About the Author

Dr. Simon Monk (Preston, UK) has a degree in Cybernetics and Computer Science and a PhD in Software Engineering. Monk spent several years as an academic before he returned to industry, co-founding the mobile software company Momote Ltd. He has been an active electronics hobbyist since his early teens and is a full-time writer on hobby electronics and open-source hardware. Dr. Monk is the author of numerous electronics books, specializing in open-source hardware platforms, especially Arduino and Raspberry Pi. He is also co-author with Paul Scherz of *Practical Electronics for Inventors,* 3rd edition. You can follow Simon on Twitter, where he is @simonmonk2.

Acknowledgments

Many thanks to all those at McGraw-Hill Education who have done such a great job in producing this book. In particular, thanks to my editor Roger Stewart and to Vastavikta Sharma, Jody McKenzie, Mike McGee, and Claire Splan.

Special thanks are due to Duncan Amos, John Heath, and John Hutchinson for their technical review of the material and encouragement.

And last but not least, thanks once again to Linda, for her patience and generosity in giving me space to do this.

Introduction

This is a book about "hacking" electronics. It is not a formal, theory-based book about electronics. Its sole aim is to equip the reader with the skills he or she needs to use electronics to make something, whether it's starting from scratch, connecting together modules, or adapting existing electronic devices for some new use.

You will learn how to experiment and get your ideas into some kind of order, so that what you make will work. Along the way, you'll gain an appreciation for why things work and the limits of what they can do, and learn how to make prototypes on solderless breadboard, how to solder components directly to each other, and how to use stripboard.

You will also learn how to use the popular Arduino microcontroller board, which has become one of the most important tools available to the electronics hacker. There are over 20 examples of how to use an Arduino with electronics in this book.

Electronics has changed. This is a modern book that avoids theory you will likely never use and instead concentrates on how you can build things using readymade modules when they are available. There is, after all, no point in reinventing the wheel.

Some of the things explained and described in the book include

- Using LEDs, including high-power Lumileds
- Using LiPo battery packs and buck-boost power supply modules
- Using sensors to measure light, temperature, vibration, acceleration, sound level, and color
- Interfacing with Arduino microcontroller boards, including using Arduino shields such as the Ethernet and LCD display shields
- Using servo and stepper motors

Some of the things described in the book that you can make along the way include

- A noxious gas detector
- An Internet-controlled hacked electric toy
- A device for measuring color
- An ultrasonic rangefinder
- A remote control robotic rover
- An accelerometer-based version of the “egg and spoon” race
- A one-watt audio amplifier
- A bug made from a hacked MP3 FM transmitter
- Working brakes and head lights that can be added to a slot car

You Will Need

This is a very practical, hands-on type of book. You will therefore need some tools and components to get the most out of it.

As far as tools go, you will need little more than a multimeter and soldering equipment.

When it comes to areas of electronics where a microcontroller would be useful, an Arduino Uno board is best. So you may wish to buy one of these microcontroller boards before attempting some of the projects.

Every component used in this book is listed in the Appendix, along with sources where it can be obtained. The majority of the components can be found in a starter kit from SparkFun, but most electronic starter kits will provide a lot of what you will need.

In many of the “how-tos,” there will be a You Will Need section. This will refer to a code in the Appendix that explains where to get the component.

How to Use This Book

The book is organized into chapters, each of which has a theme. Within each chapter, most of the numbered sections contain a "how-to" on some topic of electronics.

The book contains the following chapters:

Chapter	Title	Description
Chapter 1	Getting Started	The book starts off by telling you where you can buy equipment and components, as well as things to hack. This chapter also deals with the basics of soldering and focuses on a project to hack an old computer fan to make a fume extractor for use while soldering.
Chapter 2	Theory and Practice	This chapter introduces electronic components—or at least the ones you are likely to use—and explains how to identify them and describes what they do. It also introduces a small amount of essential theory, which you will use over and over again.
Chapter 3	Basic Hacks	This chapter contains a set of fairly basic "hacking" how-tos, introducing concepts like using transistors with example projects. It includes hacking a "push light" to make it automatically turn on when it gets dark and how to control a motor using power MOSFETs.
Chapter 4	LEDs	In addition to discussing regular LEDs and how to use them and make them flash and so on, this chapter also looks at using constant current drivers for LEDs and how to power large numbers of LEDs and laser diode modules.
Chapter 5	Batteries and Power	This chapter discusses the various types of battery, both single use and rechargeable. It also covers how to charge batteries including LiPos. Automatic battery backup, voltage regulation, and solar charging are also explained.
Chapter 6	Hacking Arduino	The Arduino has become the microcontroller board of choice for electronics hackers. Its open-source hardware design makes using a complex device like a microcontroller very straightforward. The chapter gets you started with the Arduino and includes a few simple how-tos, like controlling a relay, playing sounds, and controlling servo motors from an Arduino. It also covers the use of Arduino expansion shields.

Chapter	Title	Description
Chapter 7	Hacking with Modules	When you want to make something, you can often use readymade modules at least for part of the project. Modules exist for all sorts of things, from wireless remotes to motor drivers.
Chapter 8	Hacking with Sensors	Sensor ICs and modules are available for sensing everything from gas to acceleration. In this chapter, we explore a good range of them and explain how to use them and connect some of them to an Arduino.
Chapter 9	Audio Hacks	This chapter has a number of useful how-tos relating to electronics and sound. It includes making and adapting audio leads, as well as audio amplifiers, and discusses the use of microphones.
Chapter 10	Mending and Breaking Electronics	Mending electronics and scavenging useful parts from dead electronics are a worthy activity for the electronics hacker. This chapter explains how to take things apart and sometimes put them back together again.
Chapter 11	Tools	The final chapter of the book is intended as a reference to explain more about how to get the most out of tools such as multimeters and lab power supplies.

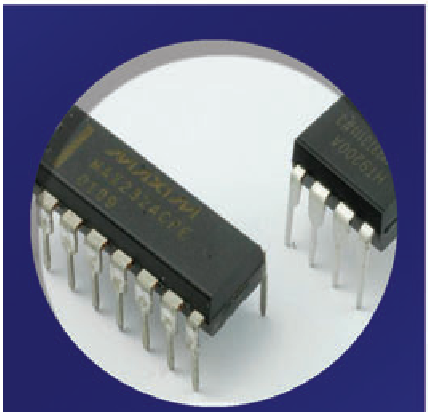
HACKING ELECTRONICS



1

Getting Started

In this first chapter, we will investigate some of the tools and techniques needed to hack electronics. We will start with a little soldering, and wire up an old computer fan to help keep the solder fumes out of our lungs.

As it says in the title, this book is all about "hacking electronics." The word "hacking" has come to mean many things. But in this book, "hacking" means "just do it!" You don't need a degree in electronic engineering to create or modify something electronic. The best way to learn is by having a go at it. You will learn as much from your mistakes as from your successes.

As you start to make things and experiment, you will likely want to understand more of the theory behind it all. Traditional electronics textbooks are pretty terrifying unless you have a good grasp of complex mathematics. This book strives to, above all else, enable you to do things first and worry about the theory later.

To get started, you will need some tools, and also find out where to get components and parts to use in your projects.

Getting Stuff

In addition to buying components and tools, there are lots of low-cost and interesting electronic consumer items that can be hacked and used for new purposes, or that can act as donors of interesting components.

Buying Components

Most component purchases happen on the Internet, although there are local electronic stores like RadioShack (in the U.S.) and Maplin (in the UK) where you can buy components. At traditional brick-and-mortar stores like those, the product range is often limited and the prices can be on the high side. They do, after all, have a shop to pay for. These stores are invaluable, however, on the odd occasion where you need something in a hurry. Perhaps you need an LED because you accidentally destroyed one, or maybe you want to look at the enclosures they sell for projects.

Sometimes it's just nice to hold a box or look at tools for real, rather than trying to size them up from pictures on a web site.

As you get into electronics, you will likely gradually accumulate a set of components and tools that you can draw from when you start a new project. Components are relatively cheap, so when I need one of something, I generally order two or three or even five if they are cheap, enough that I have extras on hand that can be used another time. This way, you will often find that when you start to work on something, you actually have pretty much everything you need already.

Component buying really depends on where you are in the world. In the U.S., Mouser and DigiKey are the largest suppliers of electronic components to the hobby electronics market. In fact, both of these suppliers sell worldwide. Farnell also supplies pretty much anything you could want, anywhere in the world.

When it comes to buying ready-made electronics modules for your projects, the SparkFun, Seeed Studio, Adafruit, and ITead Studio web sites can help. All have a wide range of modules, and much enjoyment can be had simply from browsing their online catalogs.

Nearly all the components used in this book have part codes for one or more of the suppliers I just mentioned. The only exceptions are for a few unusual modules that are better to buy from eBay.

There is also no end to the electronic components available on online auction sites, many coming direct from countries in the far east and often at extremely low prices. This is frequently the place to go for unusual components and things like laser modules and high-power LEDs that can be expensive in regular component suppliers. They are also very good for buying components in bulk. Sometimes these components are not grade A, however, so read the descriptions carefully and don't be disappointed if some of the items in the batch are dead-on-arrival.

Where to Buy Things to Hack

The first thing to consider, now that you are into hacking electronics, is an effect that your household and friends will have on you. You will become the recipient of dead electronics. But keep an eye open in your new role as refuse collector. Sometimes these "dead" items may actually be candidates for straightforward resurrection.

Another major source of useful bits is the dollar/pound/euro (delete as appropriate) store. Find the aisle with the electronic stuff: flashlights, fans, solar toys, illuminated cooling laptop bases, and so on. It's amazing what can be bought for a single unit of currency. Often you will find motors and arrays of LEDs for a lower price than you would the raw components from a conventional supplier.

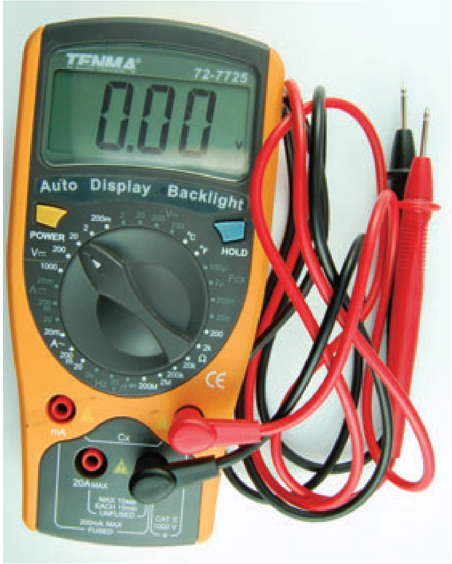
Supermarkets are another source of cheap electronics that can be hacked. Good examples of useful gadgets are cheap powered computer speakers, mice, power supplies, radio receivers, LED flashlights, and computer keyboards.

A Basic Toolkit

Don't think you are going to get through this chapter without doing some soldering. Given this, you will need some basic tools. These do not have to be expensive. In fact, when you are starting out on something new, it's a good idea to learn to use things that are inexpensive, so it doesn't matter if you spoil them. After all, you wouldn't learn the violin on a Stradivarius. Plus, what will you have to look forward to if you buy all your high-end tools now!

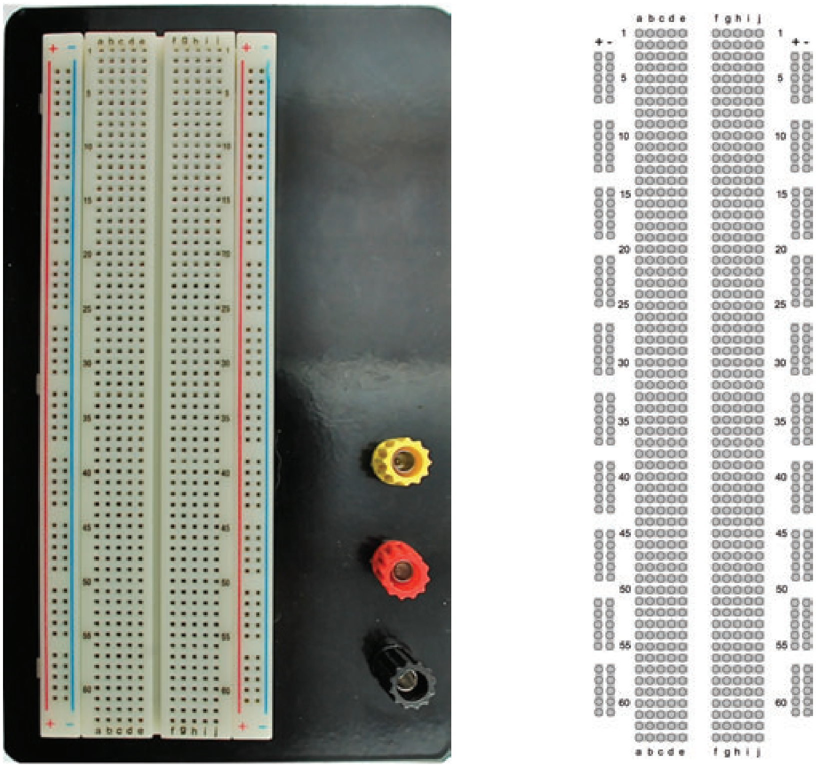
Many starter toolkits are available. For our purposes, you will need a basic soldering iron, solder, a soldering iron stand, some pliers, snips, and a screwdriver or two. SparkFun sells just such a kit (SKU TOL-09465), so buy that one or look for something similar.

FIGURE 1-1 A digital multimeter



You will also need a multimeter (Figure 1-1). I would suggest a low-cost digital multimeter (don't even think of going above USD 20). Even if you end up buying a better one, you will still end up using the other one since it's often useful to measure more than one thing at a time. The key things you need are DC Volts, DC current, resistance, and a continuity test. Everything else is fluff that you will only need once in a blue moon. Again, look for something similar to this model from SparkFun (SKU TOL-09141) or the slightly higher specification meter shown in Figure 1-1.

Solderless breadboards (Figure 1-2) are very useful for quickly trying out designs before you commit them to solder. You poke the leads of components into the sockets, and metal clips behind the holes connect all the holes on a row together. They are not expensive (see T5 in the Appendix).



(a)

(b)

Figure 1-2 Solderless breadboard

You will also need some solid core wire in different colors (T6) to make bridging connections on the breadboard. Another good idea is to buy special-purpose jumper wires with little plugs on the end—although these are useful, they are by no means essential.

Breadboard comes in all shapes and sizes, but a big one is probably most useful. Where I use solderless breadboard in the book, I use the one specified in T5 in the Appendix. This has 63 rows by 2 columns with two supply strips down each side (Figure 1-2a). It is also mounted on an aluminum base with rubber feet to stop it moving about on the table. This is a very common size of breadboard and most suppliers will have something similar.

Figure 1-2b shows how the conductive strips are arranged underneath the plastic top surface of the board. All the holes that share a common gray area beneath are connected together in rows of five connectors. The long strips down each side are used for the power supply to the components. One positive and one negative. They are color-coded red and green.

How to Strip a Wire

Let's start with some basic techniques you need to know when hacking electronics. Perhaps the most basic of these is stripping wire.

You Will Need

Quantity	Item	Appendix Code
	Wire to be stripped	T9 or scrap
1	Pliers	T1
1	Snips	T1

Whenever you hack electronics, there is likely to be some wire involved, so you need to know how to use it. Figure 1-3 shows a selection of commonly used types of wire, set beside a matchstick to give them perspective.

On the left, next to the matchstick, are three lengths of solid-core wire, sometimes called hookup wire. This is mostly used with solderless breadboard, because being made of a single core of wire inside plastic insulation, it will eventually break if it is bent. Being made of a single strand of wire does mean it is much easier to push into sockets when prototyping since it doesn't bunch up like multi-core wire.

When using it with breadboard, you can either buy already-stripped lengths of wire in various colors as a kit (see Appendix, T6) or reels of wire that you can cut to the lengths you want yourself (see Appendix, T7, T8, T9). It is useful to have at least

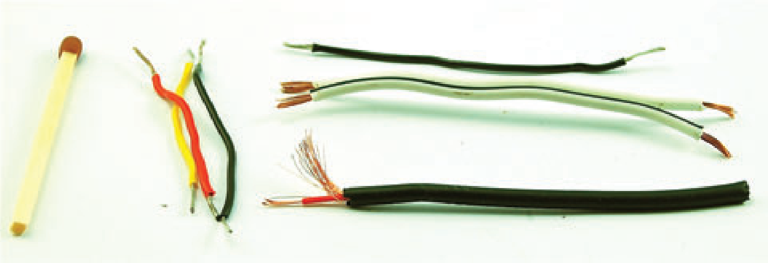


FIGURE 1-3 Common types of wire

three colors: red, yellow, and black are a good choice. It makes it easier to see how a project is connected up if you use red for the positive power supply, black for negative, and yellow for any other wires needed.

The top right of Figure 1-3 shows a length of multi-core wire, as well as some twin-strand multi-core wire. Multi-core wire is used when connecting up modules of a project. For instance, the wires to a loudspeaker from an amplifier module might use some twin, multi-core wire. It's useful to have some of this wire around. It is easily reclaimed from broken electronic devices, and relatively cheap to buy new (see Appendix, T10 and T11).

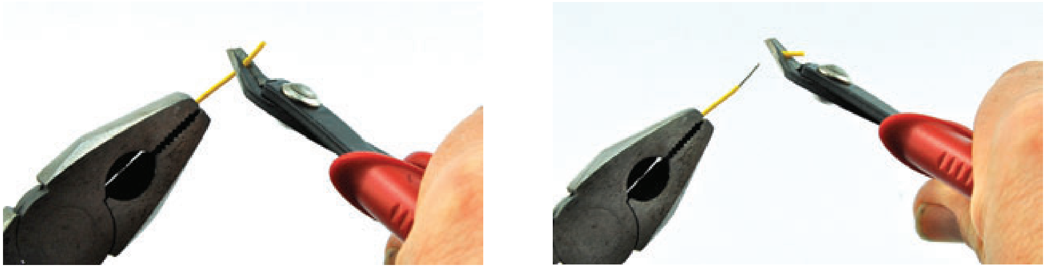
The wire at the bottom right of Figure 1-3 is screened wire. This is the type of wire you find in audio and headphone leads. It has an inner core of multi-core insulated wire surrounded by a screened wire on the outside. This type of wire is used where you don't want electrical noise from the environment such as mains hum (60 Hz electrical noise from 110V equipment) to influence the signal running through the central wire. The outer wire screens the inner wire from any stray signals and noise. There are variations of this where there is more than one core surrounded by the screening—for example, in a stereo audio lead.

Insulated wire is of no use to us unless we have a way of taking some of the insulation off it at the end, as this is where we will connect it to something. This is called "stripping" the wire. You can buy special-purpose wire strippers for this, which you can adjust to the diameter of the wire you want to strip. This implies that you know the width of the wire, however. If you are using some wire that you scavenged from a dead electronic appliance, you won't know the width. Having said that, with a bit of practice you will find you can strip wire just as well using a pair of pliers and some wire snips.

Both of these are essential tools for the electronics hacker. Neither tool needs to be expensive. In fact, snips tend to get notches in them that make them annoying to use, so a cheap pair (I usually pay about USD 2) that can be replaced regularly is a good idea.

Figures 1-4a and 1-4b show how to strip a wire with pliers and snips. The pliers are used to hold things still with a firm grip, while the snips do the actual stripping.

Grip the wire in the pliers, about an inch away from the end (Figure 1-4a). Use the snips to grip the insulation where you want to take it off. Sometimes it helps to just nip the insulation all the way around before gripping it tightly with the snips, and then pull the insulation off (Figure 1-4b).



(a) (b)

FIGURE 1-4 Stripping wire

For longer lengths of wire, you can just wrap the wire around your finger a few times instead of using pliers.

This takes a bit of practice. Sometimes you will have the snips grip it too tightly and accidentally cut the wire all the way through, while other times you won't grip it hard enough with the snips and the insulation will stay in place or stretch. Before attempting anything important, practice with an old length of wire.

How to Join Wires Together by Twisting

It is possible to join wires without soldering. Soldering is more permanent, but sometimes this technique is good enough.

One of the simplest ways of joining wires is to simply twist the bare ends together. This works much better for multi-core wire than the single-core variety, but if done properly with the single-core, it will still make a reliable connection.

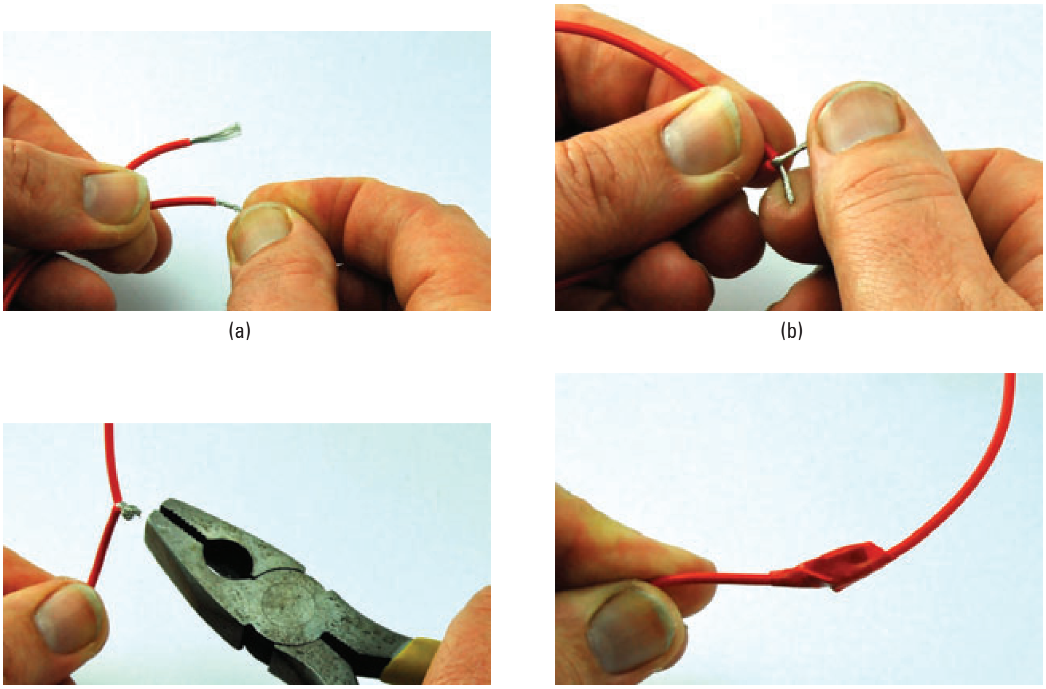
You Will Need

To try out joining two wires by twisting (there is slightly more to it than you might expect), you will need the following.

Quantity	Item	Appendix Code
2	Wires to be joined	T10
1	Roll of PVC insulating tape	T3

If you need to strip the wires first to get at the copper, refer back to the section "How to Strip a Wire."

Figures 1-5a thru 1-5d show the sequence of events in joining two wires by twisting them.



(a) (b)

(c) (d)

Figure 1-5 Joining wires by twisting

First, twist the strands of each wire up clockwise (Figure 1-5a). This just tidies up any straggling strands of the multi-core wire. Then, twist together the two pre-twisted wires (Figure 1-5b) so they are both twisting around each other. Try to avoid the situation where one of the wires twists around the second, while the second remains straight. If it does this, it is very easy for the first wire to just slip off the second. Next, twist the joined wires up into a neat little knot (Figure 1-5c). Note that a pair of pliers may be easier to use when making the knot, especially if the wire is on the thick side. Lastly, cover the joint with four or five turns of PVC insulating tape (Figure 1-5d).

How to Join Wires by Soldering

Soldering is the main skill necessary for hacking electronics.

Safety

I don't want to put you off, but … be aware that soldering involves melting metal at very high temperatures. Not only that, but melting metal that's coupled with noxious fumes. It is a law of nature that anyone who has a motorbike eventually falls off it, and anyone who solders will burn their fingers. So be careful and follow these safety tips:

- Always put the iron back in its stand when you are not actually soldering something. If you leave it resting on the bench, sooner or later it will roll off. Or you could catch the wires with your elbow and if it falls to the floor, your natural reflex will be to try and catch it—and chances are you will catch the hot end. If you try and juggle it in one hand, while looking for something or arranging some components ready to solder, sooner or later you will either solder your fingers or burn something precious.
- Wear safety glasses. Blobs of molten solder will sometimes flick up, especially when soldering a wire or component that is under tension. You do not want a blob of molten solder in your eye. If you are long-sighted, magnifying goggles may not look cool, but they will serve the dual purpose of protecting your eyes and letting you see properly.
- If you do burn yourself, run cold water over the burned skin for at least a minute. If the burn is bad, seek medical attention.
- Solder in a ventilated room, and ideally set up a little fan to draw the fumes away from you and the soldering iron. Preferably have it blowing out of a window. A fun little project to practice your wire joining skills on is making a fan using an old computer (see the section "How to Hack a Computer Fan to Keep Soldering Fumes Away").

You Will Need

To practice joining some wires with solder, you will need the following items.

Quantity	Item	Appendix Code
2	Wires to be joined	T10
1	Roll of PVC insulating tape	T3
1	Soldering kit	T1
1	Magic hands (optional)	T4
1	Coffee mug (essential)	

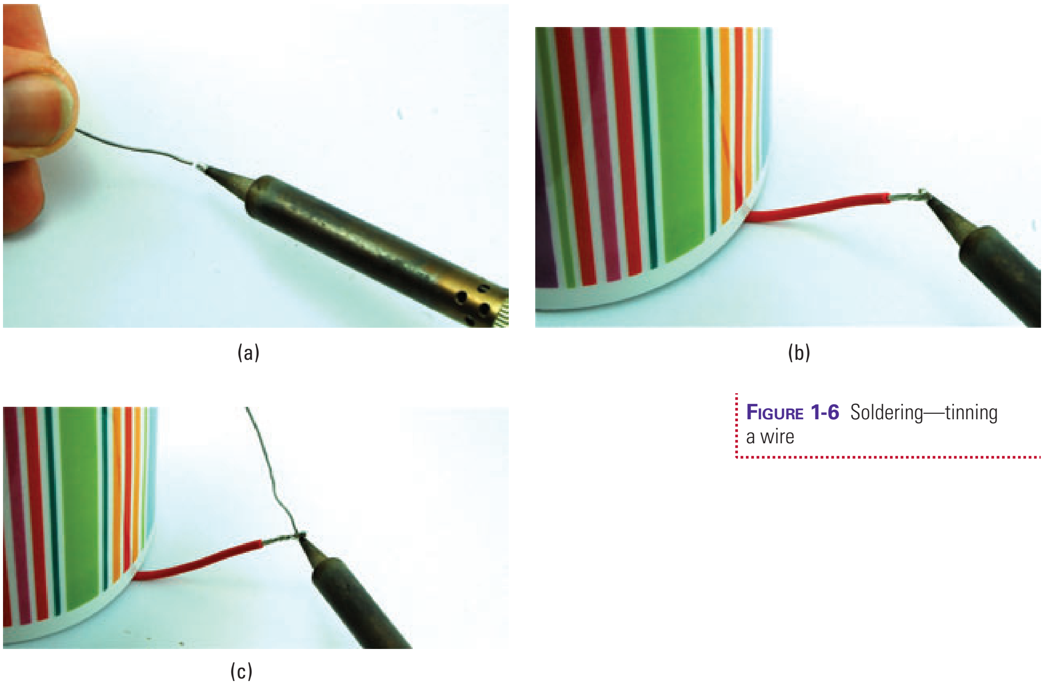
Magic hands are a great help during soldering because they solve the problem that, when soldering, you really need three hands: one to hold the iron, one to hold the solder, and one to hold the thing or things you are trying to solder. You generally use the magic hands to hold the thing or things you are trying to solder. Magic hands are comprised of a small weighted bracket with crocodile clips that can be used to hold things in place and off the work surface.

An alternative that works well for wires is to bend them a little so that the end you are soldering will stick up from the workbench. It usually helps to place something heavy like a coffee mug on the wire to keep it from moving.

Soldering

Before we get onto the business of joining these two wires, let's have a look at soldering. If you haven't soldered before, Figures 1-6a thru 1-6c show you how it's done.

1. Make sure your soldering iron has fully heated up.
2. Clean the tip by wiping it on the damp (not sopping wet) sponge on the soldering iron stand.



(a)

(b)

(c)

FIGURE 1-6 Soldering—tinning a wire

3. Touch a bit of solder onto the tip of the iron to "tin" it (see Figure 1-6a). After you have done this, the tip should be bright and shiny. If the solder doesn't melt, then your iron probably isn't hot enough yet. If the solder forms into a ball and doesn't coat the tip of the iron, the tip of it may be dirty, so wipe it on the sponge and try again.
4. Hold the soldering iron to the wire and leave it there for a second or two (Figure 1-6b).
5. Touch the solder to the wire near the soldering iron. It should flow into the wire (Figure 1-6c).

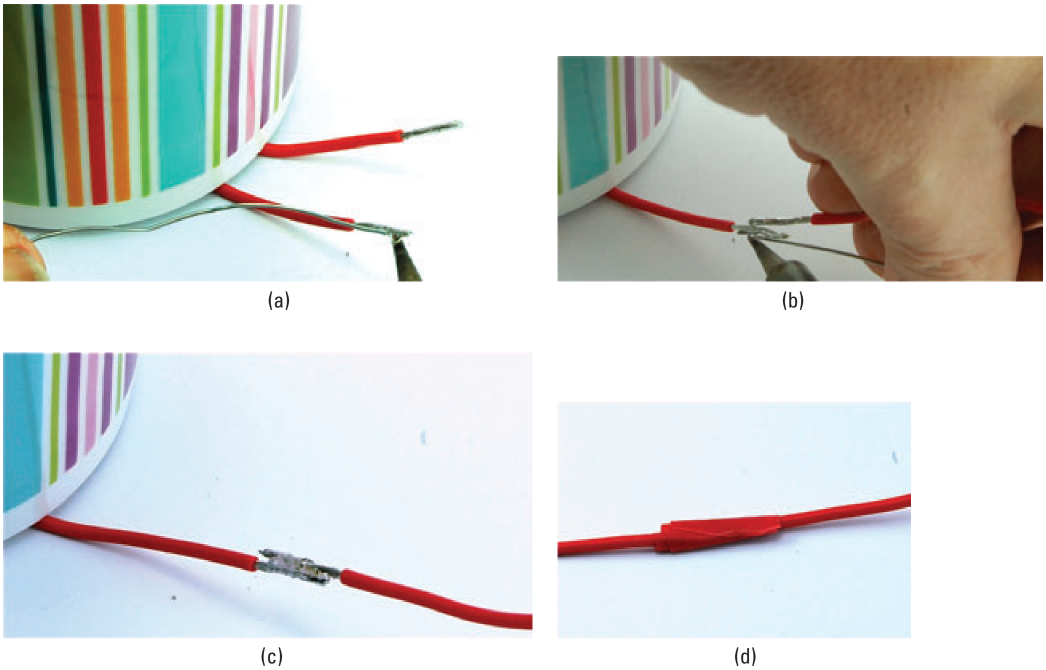
Soldering is something of an art. Some people are naturally very neat at soldering. So do not worry if your results are a bit blobby at first. You will get better. The main thing to remember is that you heat up the item you want to solder and only apply the solder when that thing is hot enough for the solder to melt onto it. If you are struggling, it sometimes helps to apply the solder to the spot where the soldering iron meets the thing being soldered.

The following section offers a bit more soldering practice for you—in this case, by soldering wires together.

Joining Wires

To join two wires with solder, you can use the same approach described in the section "How to Join Wires Together by Twisting" and then flow solder into the little knot. An alternative way—that makes for a less lumpy joined wire—is illustrated in Figures 1-7a thru 1-7d.

1. The first step is to twist each end. If it is multi-core wire (a), tin it with solder as shown in Figure 1-7a.
2. Hold the wires side by side and heat them with the iron (see Figure 1-7b). Note the chopstick technique of holding both the second wire and the solder in one hand.
3. Introduce the solder to the wires so they join together into one wire and look something like that shown Figure 1-7c.
4. Wrap the joint in three or four turns of insulating tape—half an inch is probably enough (see Figure 1-7d).



(a) (b) (c) (d)

FIGURE 1-7 Joining wires by soldering

How to Test a Connection

For the joints that we have made in the section "How to Join Wires by Soldering," it is fairly obvious that they are connected. However, especially with solid-core wire, it is not uncommon for the wire core to break somewhere under the insulation. If you own an electric guitar, you will probably be familiar with the problem of a broken guitar lead.

You Will Need

Quantity	Item	Appendix Code
1	Multimeter	T2
1	Connections to be tested	

Nearly all multimeters have a "Continuity" mode. When set in this useful mode, the multimeter will beep when the leads are connected to each other.

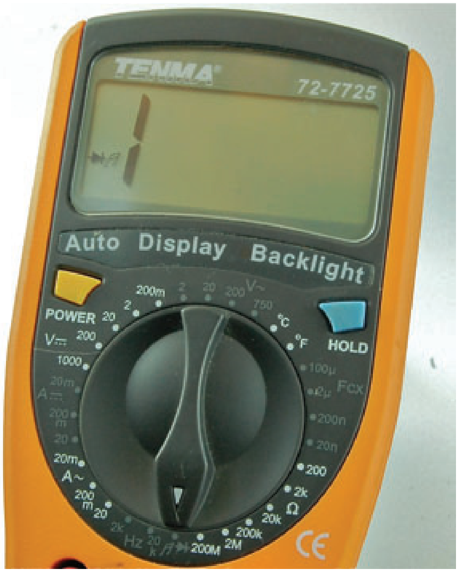


Figure 1-8 A multimeter in Continuity mode

Set your multimeter to "Continuity mode," and then try touching the leads together. Now take a length of wire and try touching the multimeter leads to each end of the wire (Figure 1-8). The buzzer should sound if the wire is okay.

You can use this technique on circuit boards. If you have an old bit of circuit board from something, try testing between the soldered connections on the same track (Figure 1-9).

If there is no connection where you would expect there to be a connection, then there may be a "dry joint," where the solder hasn't flowed properly or there is a crack in the track on the circuit board (this sometimes happens if the board gets flexed).

A dry joint is easily fixed by just applying a bit of solder and making sure it flows properly. Cracks on a circuit board can be fixed by scraping away some of the protective lacquer over the track and then soldering up the split in the track.

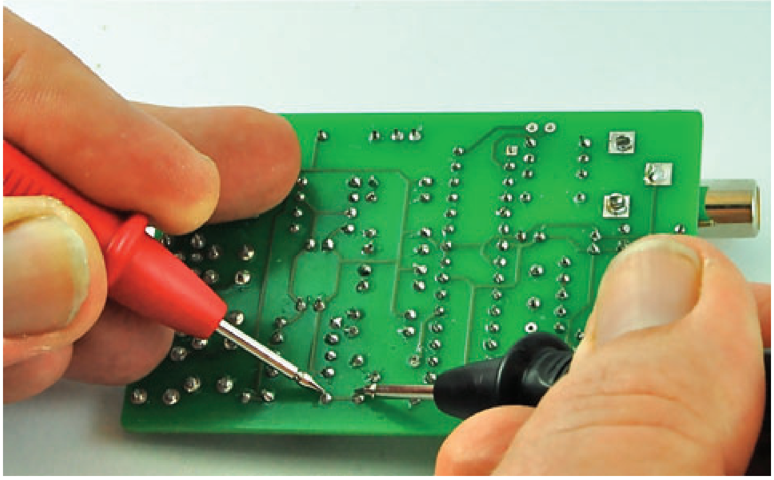

Figure 1-9 Testing a circuit board

How to Hack a Computer Fan to Keep Soldering Fumes Away

Solder fumes are unpleasant and bad for you. If you can sit by an open window while you solder, then great. If not, then this is a good little construction project to enhance your electronics hacking skills (Figure 1-10).

Okay, so it's not going to win any awards for style, but attached to my work light (which is always close to whatever I am soldering), the fumes will at least be directed away from my face.

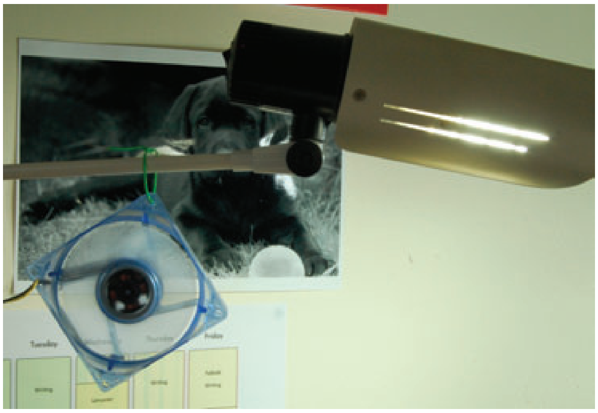

FIGURE 1-10 A homemade fume extractor

You Will Need

Quantity	Item	Appendix Code
1	Soldering equipment	T1
1	An old computer fan (two-lead)	
1	12V power supply	M1
1	SPST switch	K1

Construction

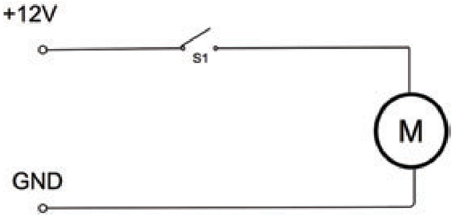

FIGURE 1-11 The schematic diagram for the fume extractor

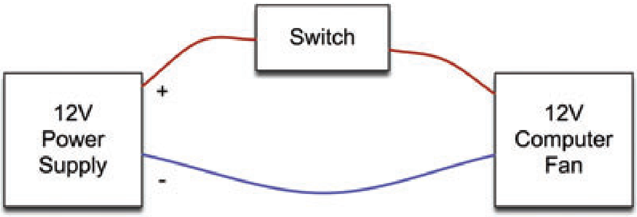
Figure 1-11 shows the schematic diagram for this mini-project.

Newcomers to electronics often view schematic diagrams like this with suspicion, thinking it better just to show the components as they actually are, with wires where wires need to be—just like in Figure 1-12. It is worth learning how to read a schematic diagram. It really isn't that hard and in the long term it will pay dividends. Not least because of the vast number of useful circuit diagrams published on the Internet. It's a bit like being able to read music. You can get so far playing by ear, but there are more options if you can read and write musical notation.

So, let's examine our schematic diagram. Over on the left we have two labels that say "+12V" and "GND." The first is the

FIGURE 1-12 The wiring diagram for the fume extractor



12V positive supply from the 12V power supply. GND actually refers to the negative connection of the power supply. GND is short for "ground" and just means zero volts. Voltage is relative, so the 12V connection of the power supply is 12V above the other connection (the GND connection). We will learn more about voltage in the next chapter.

Moving toward the right, we have a switch. This is labeled "S1," and if we had more than one switch in a schematic, they would be labeled "S2," "S3," and so on. The symbol for a switch shows how it operates. When the switch is turned to the on position, its two connections are connected together, and when it is in the off position, they aren't. It's as simple as that.

The switch is just controlling the supply of electricity to the motor of the fan (M) as if it were a faucet.

Step 1. Strip the Power Supply Leads

We have a power supply and we are going to cut the plug off the end of it and strip the wires (see the section "How to Strip a Wire"). Before you cut off the plug, make sure the power supply is NOT plugged in. Otherwise, if you snip both wires at the same time, the cutters will probably short the two connections together, which may damage the power supply.

Step 2. Identify the Power Supply Lead Polarity

Having cut the wires, we need to know which one is the positive one. To do this, let's use a multimeter. Set the multimeter to its 20V DC range. Your multimeter will probably have two voltage ranges, one for AC and one for DC. You need to use the DC range. This is often marked by a solid line above a dotted line. The AC range will either be marked as AC or have a picture of a little sine wave next to it. If you select AC instead of DC, it will not damage the meter, but you will not get a meaningful reading. (See Chapter 11 if you need more information on multimeters.)

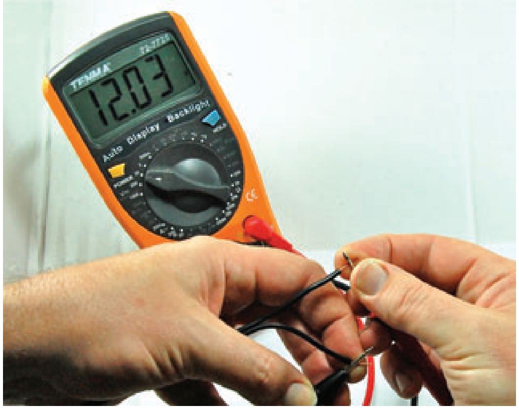


FIGURE 1-13 Using a multimeter to find the power supply polarity

First making sure that the stripped leads from the power supply are not touching, plug the power supply in and turn it on.

Now touch the two test leads from the multimeter to the leads from the power supply (Figure 1-13). If the number on the multimeter is not negative, then the red test lead of the multimeter is connected to the positive lead. Mark the lead in some way (I tied a knot in it). If the multimeter shows a negative voltage, then the leads are swapped over, so tie a knot in the power supply lead connected to the black test lead of the multimeter—in this case, this is the positive lead from the power supply.

Step 3. Connect the Negative Leads Together

Unplug your power supply. You should never solder anything that is powered up.

Cut any plug off the end of your computer fan and strip the two wires. Mine had one black (negative) and one yellow (positive) lead. Three lead fans are more complex and should be avoided. If you get the leads the wrong way around, no harm will befall you. The fan will just rotate in the opposite direction.

We are now going to join the negative lead of the fan to the negative lead (no knot) of the power supply (Figure 1-14).

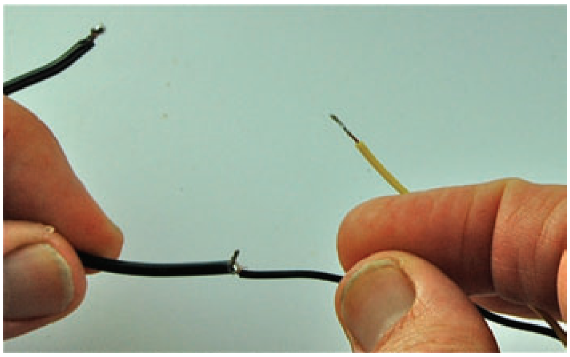

FIGURE 1-14 Connecting the negative leads together

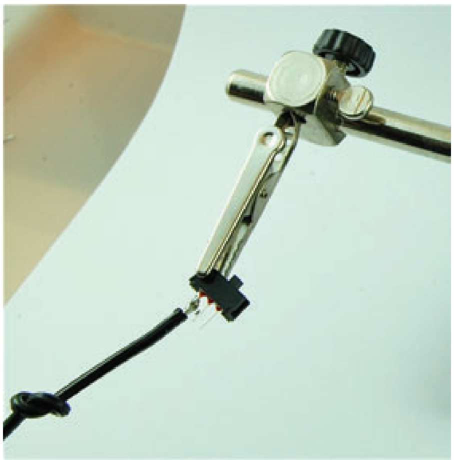

FIGURE 1-15 Connecting the positive lead to the switch

Step 4. Connect the Positive Lead to the Switch

Solder the positive lead from the power supply to one of the outer connections on the switch (it doesn't matter which). (See Figure 1-15.) It will help to tin the switch connection with a little solder before you start.

Finally, connect the remaining lead from the fan to the center connection of the switch (see Figure 1-16).

Step 5. Try It Out

Wrap the bare connections with insulating tape, plug it in, turn it on, and presto! When you flick the switch, the fan should come on.

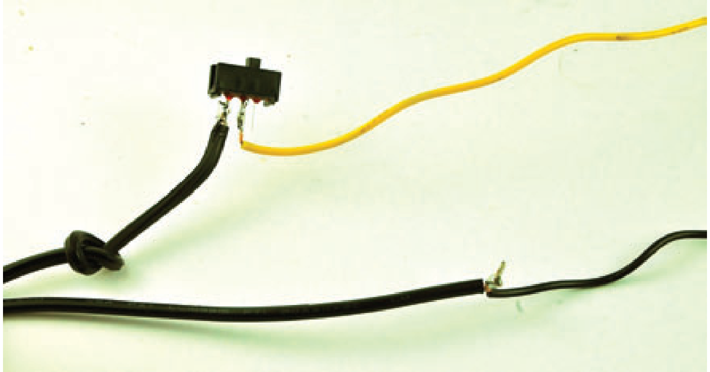

FIGURE 1-16 Connecting the fan to the switch

Summary

Now that we have the basics and are confident about a bit of soldering and dealing with wires and switches, we can now move on to Chapter 2. There, we will start looking at a few electronic components, as well as some of the basic ideas you will need to understand to successfully hack electronics.

2

Theory and Practice

There are a few fundamentals that will help us get the most out of our electronics. I have no intention of overloading you with theory, so you may find you come back to this chapter as and when you need to. But before we start on any theory, let's look at getting together some of the components we will use.

How to Assemble a Starter Kit of Components

In Chapter 1, we assembled a few tools and did some soldering. The only thing we made used a scavenged computer fan, an off-the-shelf power supply, and a switch.

Certain components you will find that you use over and over again. To get yourself a basic stock of components, I recommend you buy a starter kit. SparkFun sells such a kit (see the Appendix, K1), but it does not contain any resistors, so you will need to buy a resistor set, too (K2). Once you have these, you will have a useful collection of components that should cover 80 percent of what you need.

Other suppliers sell starter kits, and although none of them will contain everything you need for this book, most will give you a very good starting point.

You Will Need

The SparkFun Starter Kit contains the following items, and the items used directly in this book are marked with a *, so if buying an alternative kit, look for one that has the majority of these components. Also see the Appendix for a list of other components used in the book.

Quantity	Item	Quantity	Item
10	0.1uF capacitor *	3	20-pin male header *
5	100uF capacitor *	3	Mini power switch *
5	10uF capacitor *	2	Push buttons *
5	1uF capacitor	1	10k trimpot *
5	10nF capacitor	2	LM358 OpAmp
5	1nF capacitor	2	3.3V regulator
5	100pF capacitor	2	5V regulator *
5	10pF capacitor	1	555 timer *
5	1N4148 diode	1	Green LED *
5	1N4001 diode *	1	Yellow LED *
5	2N3906 PNP transistor	1	Red LED *
5	2N3904 NPN transistor *	1	7-segment red LED
3	20-pin female header	1	Mini photocell *

The separate SparkFun resistor kit (K2) contains resistors of the following values:

0Ω, 1.5Ω, 4.7Ω, 10Ω, 47Ω
110Ω, 220Ω, 330Ω, 470Ω, 680Ω
1kΩ, 2.2kΩ, 3.3kΩ, 4.7kΩ, 10kΩ
22kΩ, 47kΩ, 100kΩ, 330kΩ, 1MΩ

How to Identify Electronic Components

So, what have we just bought here? Let's go through the components in the SparkFun starter kits and explain what they do, starting with the resistors.

Resistors

Figure 2-1 shows an assortment of resistors. Resistors come in different sizes to be able to cope with different amounts of power. High-power resistors are physically big to cope with the heat they produce. Since "parts getting hot" is generally a bad thing in electronics, we will mostly avoid that. Nearly all of the time we can use the 0.25-watt resistors as provided in the SparkFun kit, which are perfect for general use.

As well as having a maximum power rating, resistors also have a "resistance." As the word suggests, resistance is actually

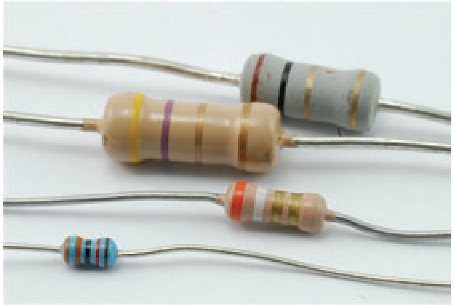

FIGURE 2-1 Assorted resistors

resistance to the flow of current. So a high-resistance resistor will not allow much current to flow, while a low-value resistor will allow lots of current to flow.

Resistors are the most commonly used component you can find. Since we will be using them a lot, we will go into greater detail on the subject in the section "What Are Current, Resistance, and Voltage?" later in this chapter.

Resistors have little stripes on them that tell you their value. You can learn to read the stripes (more in a moment on that) or you can avoid all of this by storing them in a bag or in the drawer of a component box with the value written on the box or bag. If in doubt, check the value with the resistance measurement feature of your multimeter.

However, an essential piece of geekiness is to know your resistor color-codes. Each color has a value, as shown next:

Color	Value
Black	0
Brown	1
Red	2
Orange	3
Yellow	4
Green	5
Blue	6
Violet	7
Gray	8
White	9
Gold	1/10
Silver	1/100

Gold and silver, as well as representing the fractions 1/10 and 1/100, are also used to indicate how accurate the resistor is. So gold is ±5% and silver is ±10%.

There will generally be three of these bands grouped together at one end of the resistor. This is followed by a gap, and then a single band at the other end of the resistor. The single band indicates the accuracy of the resistor value. Since none of the projects in this book require very accurate resistors, there is no need to select your resistors on the basis of accuracy.

Figure 2-2 shows the arrangement of the colored bands. The resistor value uses just the three bands. The first band is the first digit, the second the second digit, and the third "multiplier" band is how many zeros to put after the first two digits.

So, a 270Ω (*ohm*) resistor will have first digit 2 (red), second digit 7 (violet), and a multiplier of 1 (brown). Similarly, a 10KΩ resistor will have bands of brown, black, and orange (1, 0, 000).

In addition to fixed resistors, there are also variable resistors (a.k.a., potentiometers or pots). This comes in handy with volume controls, where turning a knob changes the resistance and alters the level of sound.

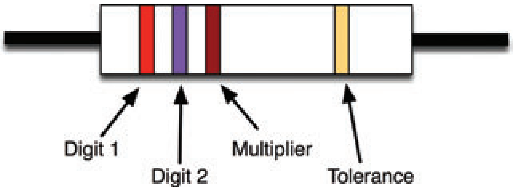

FIGURE 2-2 Resistor stripes

Capacitors

When hacking electronics, you will occasionally need to use a capacitor. Luckily, you do not need to know much about what they do. They are often used to head-off problems like the instability of a circuit or unwanted noise. Their use is often given a name like "decoupling capacitor" or "smoothing capacitor." There are simple rules you can follow about where you need a capacitor. These will be highlighted as we encounter them in later sections.

For the curious, capacitors store charge, a bit like a battery, but not much charge, and they can store the charge and release it very quickly.

Figure 2-3 shows a selection of capacitors.

If you look closely at the second capacitor from the left, you will see the number 103. This is actually the value of the capacitor in picofarads. The unit of capacitance is farad, but a 1F capacitor would be considered a huge capacitor, storing a great deal of charge. So, while such beasts do exist, everyday capacitors are either measured in nanofarads (nF = 1/1,000,000,000F) or microfarads (μF = 1/1,000,000F). You will also find capacitors in the picofarad range (pF = 1/1,000,000,000,000F).

Returning to 103. … Rather like resistors, this means 10 and then 3 zeros, in units of pF. So in this case that's 10,000pF or 10nF.

Larger capacitors, like those on the right of Figure 2-3, are called electrolytic capacitors. They are usually in the μF

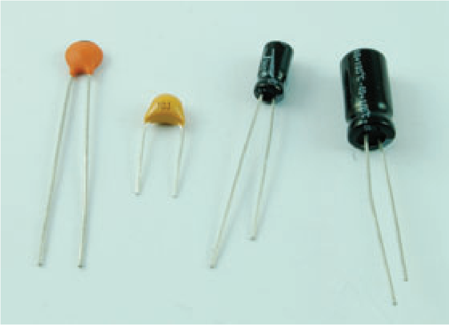

FIGURE 2-3 Assorted capacitors

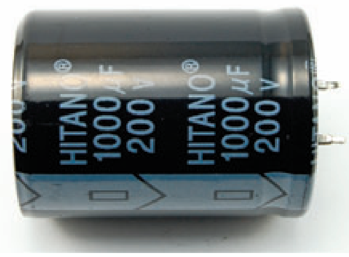

Figure 2-4 An electrolytic capacitor

range and have their value written on their side. They also have a + and a – side, and unlike most other capacitors must be connected the right way around.

Figure 2-4 shows a large electrolytic, with value (1000μF) and its negative lead clearly indicated at the bottom of the figure. If the capacitor has one lead longer than the other, the longer one will normally be the positive lead.

The capacitor in Figure 2-4 also has a voltage written on it (200V). This is the capacitor's maximum voltage. So if you put more than 200V across its leads, it will fail. Big electrolytic capacitors like this have a reputation for failing spectacularly and may burst, spewing forth goo.

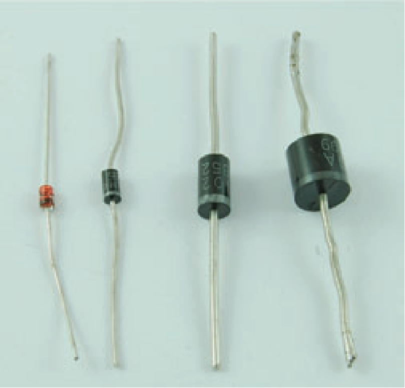

Figure 2-5 A selection of diodes

Diodes

You will occasionally need to use diodes. They are kind of a one-way valve, only allowing current to flow in one direction. They are therefore often used to protect sensitive components from accidental reverse voltage that could damage them.

Diodes (Figure 2-5) have a stripe at one end. That end is called the cathode, while the other end is called the anode. We will hear more about diodes later.

As with resistors, the bigger the diode physically, the more power it can cope with before it gets too hot and expires. Ninety percent of the time, you will just be using one of the two diodes on the left-hand side of the figure.

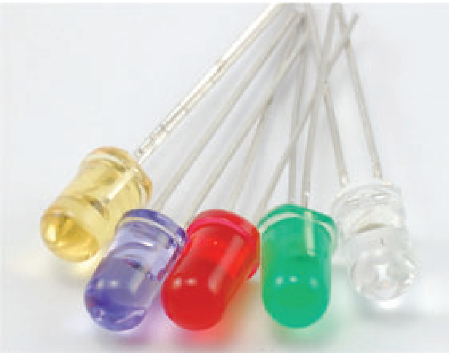

Figure 2-6 Assorted LEDs

LEDs

LEDs light up, and generally look pretty. Figure 2-6 shows a selection of LEDs.

LEDs are a little sensitive, so you should not connect them directly to a battery. Instead you have to use a resistor to reduce the current flowing into the LED. If you do not do this, the LED will probably die almost instantly.

Later on, we will see how to select the right resistor for the job.

Just like regular diodes, LEDs have a positive and a negative lead (anode and cathode). The anode is the longer of the two leads. There is also usually a flat side to the LED case on the cathode side.

As well as single LEDs, you also get LEDs in more complicated arrangements within a single package. Figure 2-7 shows some interesting-looking LEDs.

From left to right, these LEDs are an ultraviolet LED, an LED with both red and green LEDs in the same package, a high-power RGB (red, green, blue) LED that can be controlled to produce any color of light, a seven-segment LED display, and an LED bar graph display.

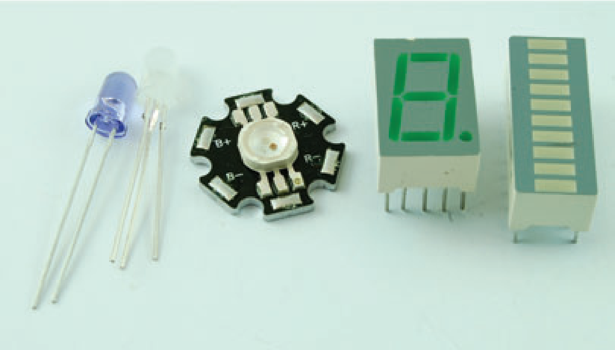

FIGURE 2-7 More LEDs

This is just a small selection of LED types. There are many others to choose from. In later sections, we will explore some of these more exotic LEDs.

Transistors

While transistors can be used in audio amplifiers and in many circumstances, for the casual electronics hacker, the transistor can be thought of as a switch. But rather than a switch controlled by a lever, it is a switch that switches a big current, yet is controlled by a small current.

Generally speaking, the physical size of the transistor (Figure 2-8) determines how big the current that it switches can be before it starts producing smoke.

Of the transistors in Figure 2-8, the right-hand two are quite specialized and employed for high power use.

Generally, the rule for a component is that if it's ugly and has three legs, it's probably some kind of transistor.

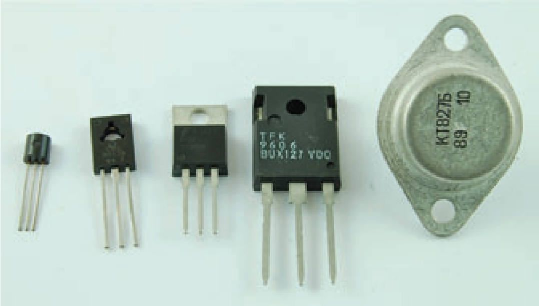

FIGURE 2-8 Transistors

Integrated Circuits

An integrated circuit (IC), or just "chip," is a load of transistors and other components printed onto silicon. The purpose of the IC varies wildly. It can be a microcontroller (mini-computer), or an entire audio amplifier, or a computer memory, or any one of thousands of other possibilities.

ICs make life easy, because as they say, often "there's a chip for that." Indeed, if there is something you want to make, there may well be a chip for it already, and if there isn't, then there will probably be a general-purpose chip that takes you halfway there.

ICs look like bugs (Figure 2-9).

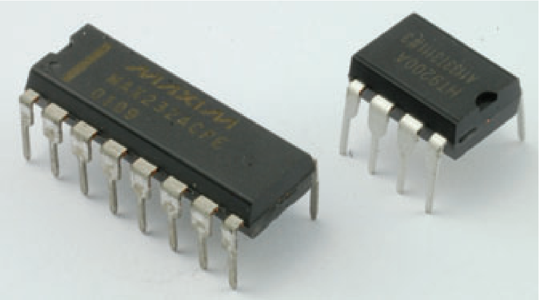

Figure 2-9 Integrated circuits

Other Stuff

There are so many other components out there, some of which are very familiar, such as batteries and switches. Others are less familiar and include potentiometers (variable resistors found in volume controls), phototransistors, rotary encoders, light dependent resistors, and so on. We will explore these as they arise later in the book.

Surface Mount Components

Let's touch a little on the subject of surface mount devices (SMDs). These components are just resistors, transistors, capacitors, ICs, and so on, but in tiny packages designed to be soldered onto the top surface of circuit boards by machines.

Figure 2-10 shows a selection of SMDs.

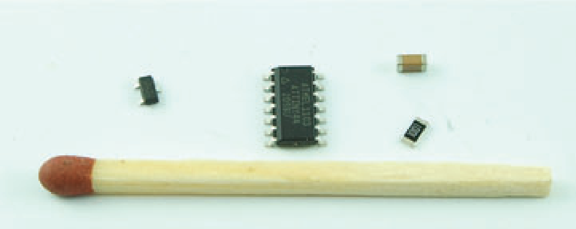

Figure 2-10 Surface mount components

The matchstick shows you just how small these devices are. It is perfectly possible to do surface mount soldering by hand, but you need a steady hand and a high-quality soldering iron. Not to mention a lot of patience. You are also likely to need a means of making circuit boards, as they are not easy to use with breadboard or other prototyping tools.

In this book, we mostly look at using the conventional "through-hole" components rather than SMDs. However, as your experience grows and you feel you might like working with SMDs, do not be afraid to try.

What Are Current, Resistance, and Voltage?

Voltage, current, and resistance are three properties that are fundamental to almost everything you will do in electronics. They are intimately related, and if you can master the relationship between them, you will be a wise hacker indeed.

Please take the time to read and understand this little bit of theory. Once you understand it, many other things should automatically fall into place.

Current

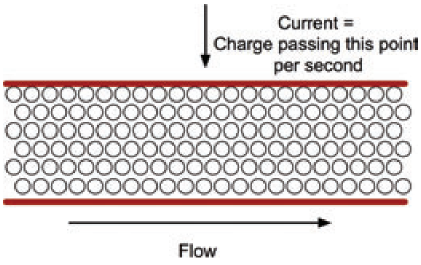

Figure 2-11 Current

The problem with electrons is that you cannot see them, so you just have to imagine how they do things. I like to think of electrons as little balls flowing through pipes. Any physicists reading this will probably be clutching their heads or hurling this book to the floor in disgust now. But it works for me.

Each electron has a charge and it's always the same—lots of electrons, lots of charge, few electrons, and a little bit of charge.

Current, rather like the current in a river, is measured by counting how much charge passes you per second (Figure 2-11).

Resistance

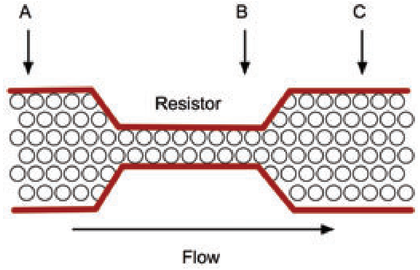

Figure 2-12 A resistor

A resistor's job is to provide resistance to the flow of current. So, if we keep thinking about our river, it is like a constriction in a river (Figure 2-12).

The resistor has reduced the amount of charge that can pass by a point. And it doesn't matter which point you measure at (A, B, or C) because, if you look upstream of the resistor, the charge is hanging around waiting to move through the resistor. Therefore, less is moving past A per second. In the resistor (B), it's restricted.

The "speed" analogy does not really hold true for electrons, but one important point is that the current will be the same wherever you measure it.

Imagine what happens when a resistor stops too much current from flowing through an LED.

Voltage

Voltage is the final part of the equation (that we will come to in a minute). If we persist with the water-in-a-river analogy, then voltage is like the height that the river drops over a given distance (Figure 2-13).

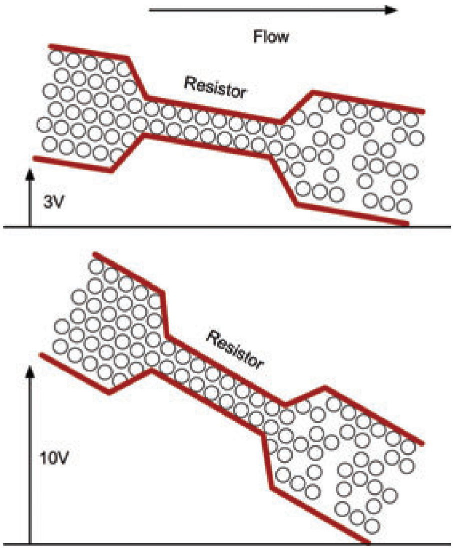

FIGURE 2-13 Voltage

As everyone knows, a river that loses height quickly flows fast and furious, whereas a relatively gently sloped river will have a correspondingly gentle current.

This analogy helps with the concept of voltage being relative. That is, it does not matter if the river is falling from 10,000 ft to 5,000 ft or from 5,000 ft to 0 ft. The drop is the same and so will be the rate of flow.

Ohm's Law

Before we get into the math of this, let's think for a moment about current, voltage, and resistance and how they relate to each other.

Try this little quiz. Think in terms of the river if you find it helps.

1. If the voltage increases, will the current (a) increase or (b) decrease?
2. If the resistance increases, will the current (a) increase or (b) decrease?

Did you get the answers (a) and (b) correct, respectively?

If you write this down as an equation, it is called Ohm's law and can be written as:

$$I = V / R$$

I for current (I guess "C" was already taken), V for Volts, and R for resistance.

So, the current flowing through a resistor, or any wire connecting to it, will be the voltage across the resistor divided by the resistance of the resistor.

The units of resistance are in Ω (the abbreviation for ohms), while units of current are in A (short for amps, which is short for amperes) and in voltage V (the easy one).

So, if we have a voltage of 10V across a resistor of 100Ω the current flowing will be:

$$10V / 100\Omega = 0.1A$$

For convenience, we often use mA (1/1000 of an amp). So 0.1A is also 100mA.

That's enough about Ohm's law for now, we will meet it again later. It is the single most useful thing you can know about electronics. In the next section, we will look at the only other truly essential math you will need—power.

What Is Power?

Power is all about energy and time. So, in a way, it's a bit like current. But, instead of being the amount of charge passing a point, it is the amount of energy transformed into heat per second when a current passes through something that resists the flow (like a resistor). Forget the river, it doesn't really help much here.

Restricting the flow of a current generates heat, and the amount of heat generated can be calculated as the voltage across a resistor times the current flowing through it. The units of power are the watt (W). You would write this in math as:

$$P = I \times V$$

So, in our earlier example, we had 10V across a 100Ω resistor, so the current through the resistor was 100mA and will generate 0.1A × 10V, or 1 W of power. Given that the resistors that we have from the SparkFun kit are 250 mW (0.25 W). Our resistor will get hot and may eventually break.

If you don't know the current, but you do know the resistance, another useful formula for calculating the power is:

$$P = V^2 / R$$

Or, power is voltage squared (times itself) divided by the resistance. So, for the example earlier:

$$P = 10 \times 10 / 100 = 1\ W$$

That's reassuringly the same answer as we got before.

Most components have a maximum power rating like this, so when selecting a resistor, transistor, diode, and so on, it is worth doing a quick check and multiplying the voltage across the component by the current that you expect to flow through it. Then, choose a component with a maximum power rating comfortably greater than the expected power.

Power is the best measure of how much electricity is being used. It is the electrical energy being used per second, and unlike current it can be compared for devices operating from

Device	Power
Battery-powered FM radio (volume down)	20 mW
Battery-powered FM radio (volume up)	500 mW
Arduino Uno microcontroller board (9V supply)	200 mW
Home WiFi router	10 W
Compact fluorescent (low-power) light bulb	15 W
Filament light bulb	60 W
LCD TV 40-inch	200 W
Electric kettle	3000 W (3 kW)

TABLE 2-1 Power Usage

both 110 volt outlets and low voltage. It is good to have a basic understanding of just how much—or how little—electricity devices use. Table 2-1 shows some devices you might find around the home and lists how much power they use.

So, now you know why you don't get battery-powered kettles!

How to Read a Schematic Diagram

Hacking electronics often involves trawling the Internet, looking for people who have made something like the thing you want to make or adapt. You will often find schematic diagrams that tell you how to make and do things. So you need to be able to understand these schematics in order to turn them into real electronics.

These may at first sight seem a little baffling, but schematics obey a few simple rules and tend to use the same patterns over and over again. So there is a lot less to learn than you might think.

Ponder Figure 2-14 while we consider some of these rules—or more accurately conventions—because sometimes they are broken.

Figure 2-14 goes a long way to explaining why we sometimes talk of electronic circuits. It's kind of a loop. The current is flowing out of the battery, through the switch (when it's closed), through the resistor and LED (D1), and then back to the battery. The lines on the schematic can be thought of as perfect wires without any resistance.

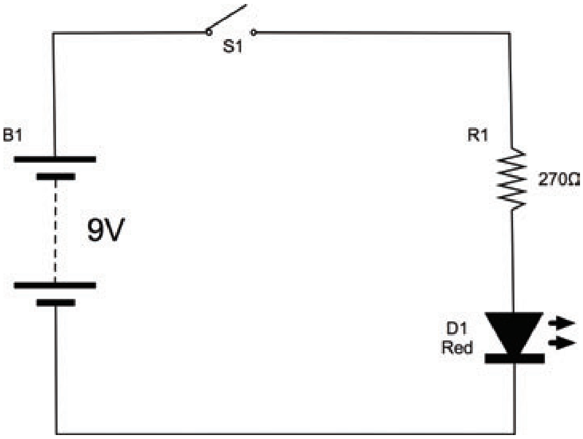

FIGURE 2-14 A simple schematic

The First Rule of Schematics: Positive Voltages Are Uppermost

A convention that most people follow when drawing a schematic is to put the higher voltages near the top, so on the left-hand side of the diagram, we have a 9V battery. The bottom of the battery is at 0V or GND (Ground), while the top of the battery will by 9V higher than that.

Notice that we draw the resistor R1 above the LED (D1). This way, we can think of some of the voltage as being lost across the resistor, before the remainder is lost through the diode and flows back to the negative connection of the battery.

Second Rule of Schematics: Things Happen Left to Right

Western civilization invented electronics and writes from left to right. You read from left to right and, culturally, more things happen from left to right. Electronics is no different, so it is common to start with the source of the electricity—the battery or power supply on the left—and then work our way from left to right across the diagram.

So, next we have our switch, which controls the flow of the electricity, and then the resistor and LED.

Names and Values

It is normal to give every component in a schematic a name. So, in this case the battery pack is called B1, the switch S1, the resistor R1, and the LED D1. This means that when you go from a schematic to a breadboard layout and eventually a circuit board, you can see which components on the schematic correspond to which components on the breadboard or circuit board.

It is also normal to specify the value of each of the components where appropriate. So, for example, the resistors' value of 270Ω is marked on the diagram. The rest of the components don't need much else said about them.

Component Symbols

Table 2-2 lists the most common circuit symbols you will encounter. This is nothing like a complete list, but we will discuss other symbols later in the book.

There are two main styles of circuit symbol: American and European. Fortunately, they are similar enough to avoid difficulties in recognizing them.

In this book, we will use the U.S. circuit symbols.

Symbol (U.S.)	Symbol (European)	Photo	Component	Use
			Resistor	Resisting
			Capacitor	Temporary charge storage
			Capacitor (polarized)	
			Transistor (bipolar NPN)	Using a small current to control a larger current
			Transistor (MOSFET N-channel)	Using a very small current to control a larger current
			Diode	Prevents current from flowing in the wrong direction
			LED	Indication and illumination
			Battery	Power supply
			Switch	Turning things on and off; control

TABLE 2-2 Common Schematic Symbols

Summary

In the next chapter, we get a much more practical look at some basic hacks and hone our electronic construction skills. This includes using prototyping boards and taking our soldering beyond simply connecting wires to other wires.

We will also learn how to use solderless breadboard so we can build electronics quickly and get underway.

Basic Hacks

This chapter contains a set of fairly basic “hacking” how-tos. These build and use various electronic construction techniques. So this is probably a good chapter to at least skim through so that when you attempt more advanced how-tos, you can refer back to it if needed.

How to Make a Resistor Get Hot

Sometimes things will get hot when you are hacking electronics. It’s always better when this is expected rather than when it’s a surprise, so it’s worth doing a little experimenting in this area.

You Will Need

Quantity	Item	Appendix Code
1	100Ω 0.25-watt resistor	K2
1	4 × AA battery holder	H1
1	4 × AA batteries (the rechargeable type is a good idea)	

Figure 3-1 shows the schematic diagram.

The Experiment

All we will do is connect the 100Ω resistor across the battery terminals and see how hot it gets.

Caution Be careful when doing this because the resistor’s temperature will rise to about 50°C/122°F. The resistor’s leads, however, will not get very hot.

We are using a battery holder that takes four AA cells, each providing about 1.5V. They are each connected, one after the other, providing us with 6V total. Figure 3-2 shows how the batteries are actually connected within the battery box as a schematic diagram. In this kind of arrangement, the batteries are said to be in series.

Figure 3-3 shows the resistor heater in action.

Simply touch a finger to the resistor to confirm it's hot.

Is this bad/good? Will the resistor eventually break because it's warm? No, it won't. Resistors are designed to cope with a bit of heat. If we do the math, the power that the resistor is burning is the voltage squared divided by the resistance, which is:

(6 × 6) / 100 = 0.36W

If it is a 0.25-W resistor, then we are exceeding its maximum power. This would be a foolish thing to do if we were designing a product for mass production. However, that's *not* what we are doing, and the chances are the resistor would continue to work like that indefinitely.

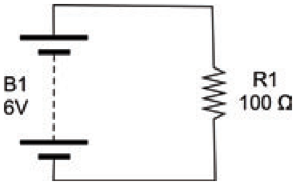

FIGURE 3-1 The schematic for heating a resistor

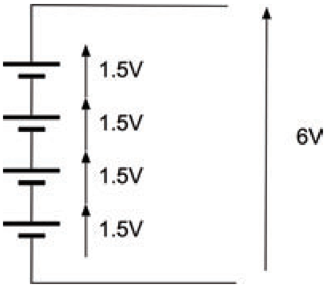

FIGURE 3-2 The schematic diagram for a battery holder

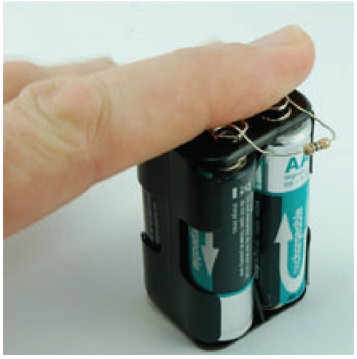

FIGURE 3-3 Making a resistor get hot

How to Use Resistors to Divide a Voltage

Sometimes voltages are too big. For example, in an FM radio, the signal going from the radio part to the audio amplifier part will be deliberately too large so it can be reduced using the volume knob.

Another example might be when you have a sensor that produces a voltage between 0 and 10V but you want to connect it to an Arduino microcontroller that expects it to be between 0 and 5V.

A very common technique in electronics is to use a pair of resistors (or a single variable resistor) as a "voltage divider."

You Will Need

Quantity	Item	Appendix Code
1	10kΩ trimpot (tiny variable resistor)	K1, R1
1	Solderless breadboard	T5
	Solid-core jumper wire	T6
1	4 × AA battery holder	H1
1	4 × AA batteries	
1	Battery clip	H2
1	Multimeter	T2

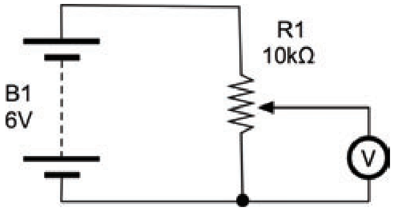

FIGURE 3-4 A voltage divider schematic diagram

Figure 3-4 shows the schematic diagram for our experiment. There are a couple of new schematic symbols here. The first is the variable resistor (or pot). This looks like a regular resistor symbol, but has a line with an arrow connecting to the resistor. This is the moving slider connection of the variable resistor.

The second new symbol is the circle with a "V" in it. This is a voltmeter, which in our case is the multimeter set to its DC voltage range.

The variable resistor we will use has three leads. One lead is fixed at each end of a conductive track, while a third connection to the central slider moves from one end of the track to the other. The overall resistance of the whole track is 10kΩ.

Our voltage in is going to be supplied from the battery pack and will be roughly 6V. We are going to use a multimeter to measure the output voltage and see how much it is being reduced by our voltage divider.

If you remember, the grey bars indicate where the connections underneath the holes are connected together. Take some time to follow the lines on the stripboard and reassure yourself that everything is connected in the same way as the schematic (Figure 3-4).

Plug the trimpot into the breadboard as shown, and then wire up the battery by carefully pushing the leads into the + and – power supply lines on the breadboard: red to +, black to –. If you struggle to get the multi-core wires of the battery clip into the holes, solder a bit of solid-core wire to the end of the leads.

Attach wires between the positive supply and the top connection of the trimpot, and the negative supply and the bottom connection of the trimpot. Finally, attach the multimeter. If your multimeter has alligator clips, use these in preference to the normal probes, clipping short jumper wires into the alligator clips and then pushing the other ends into the positions shown in Figure 3-5. When you have done all this, your breadboard should look something like Figures 3-6a and 3-6b.

Turn the trimpot to its fully clockwise position. The multimeter should read 0V (Figure 3-6a). Now turn it fully anti-clockwise and it should read something around 6V (Figure 3-6b)—in other words, the full battery voltage. Finally, turn it to roughly the middle position and you should see that the meter indicates about 3V (Figure 3-6c).

Think of the variable resistor as behaving a bit like two resistors, R1 and R2, as shown in Figure 3-7.

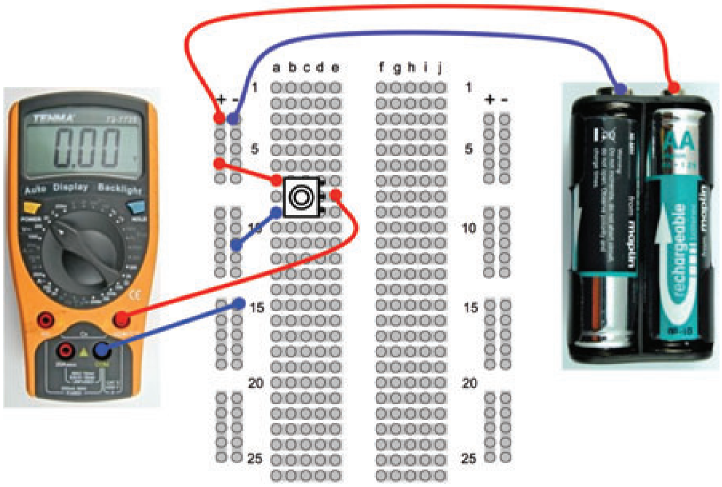

FIGURE 3-5 A voltage divider breadboard layout

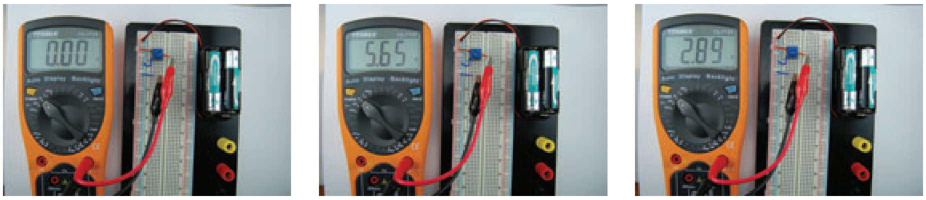

(a) (b) (c)

FIGURE 3-6 A voltage divider breadboard

The formula to calculate Vout if we know Vin, R1 and R2 is as follows:

$$Vout = Vin * R2 / (R1 + R2)$$

So, if R1 and R2 are both 5 kΩ and Vin is 6V, then:

$$Vout = 6V * 5k\Omega / (5k\Omega + 5k\Omega) = 30 / 10 = 3V$$

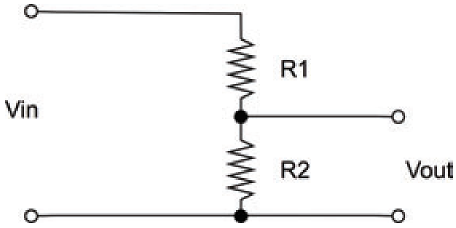

FIGURE 3-7 A voltage divider with fixed resistors

This ties in with what we found when we put the trimpot to its middle position. It is exactly the same as having two fixed resistors of 5 kΩ each.

As with many of the calculations you make in electronics, people have made handy calculating tools. If you type "voltage divider calculator" into a search engine, you will find them. One such example can be found here: www.electronics2000.co.uk/calc/potential-divider-calculator.php.

These calculators will also usually match to the nearest available fixed resistor value.

How to Convert a Resistance to a Voltage (and Make a Light Meter)

An LDR (light-dependent resistor; a.k.a., photoresistor) is a resistor whose resistance changes depending on the amount of light falling on its transparent window. We will use one of these devices to demonstrate the idea of converting a resistance to a voltage by using it as one-half of a potential divider.

You Will Need

Quantity	Item	Appendix Code
1	Light-dependent resistor	K1, R2
1	Solderless breadboard	T5
	Solid-core jumper wire	T6
1	4 × AA battery holder	H1
1	4 × AA batteries	
1	Battery clip	H2
1	Multimeter	T2

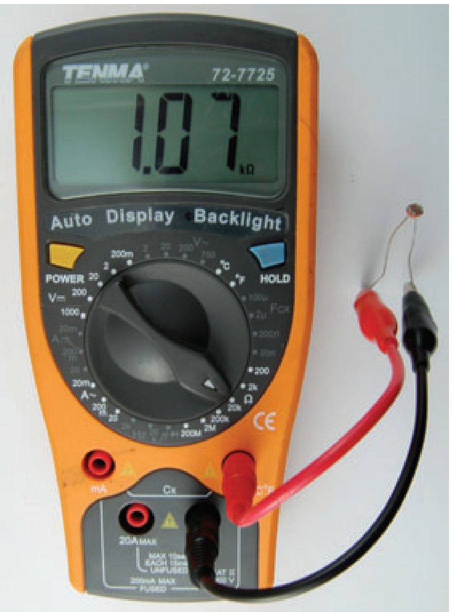

FIGURE 3-8 Measuring the LDR resistance

Before we get the breadboard out, let's just experiment directly with the LDR. Figure 3-8 shows the LDR connected directly to the multimeter on its 20kΩ resistance setting. As you can see, the resistance of my LDR was 1.07kΩ. Putting my hand over the LDR to screen out some of the light increased that resistance to a few tens of kΩ. So, the way the LDR works, the more light that reaches it, the lower the resistance.

Microcontrollers such as the Arduino can measure voltages and do things with them, but not directly measure resistance. So to convert our LDR's resistance into a more easily used voltage, we can put it in a voltage divider as one of the resistors (Figure 3-9).

Note that the symbol for the LDR is like a resistor but with little arrows pointing to it to indicate its sensitivity to light.

We can make up this schematic on our breadboard, this time setting our multimeter to the 20V DC range and watching how the voltage changes as we cover the LDR to reduce the light getting to it (Figures 3-10 and 3-11).

Hack a Push Light to Make It Light Sensing

Battery-powered push lights are one of the many glorious bargains you are likely to find in a dollar/euro/pound store. These are intended for use in cupboards and other dark locations where a bit of extra light would be useful. Push them once and they light, push them again and they turn off.

It will not surprise you to hear that we are going to use our LDR to turn the light on and off. But we are also going to use a transistor.

Our approach will be to get it working on breadboard first and then solder up the design onto the push light. In fact, we will use a single LED in place of the push lamp until we know that it will work.

You Will Need

Quantity	Name	Item	Appendix Code
1	R1	Light-dependent resistor	K1, R2
1	T1	Transistor 2N3904	K1, S1
1	R2	Resistor 10kΩ	K2
1*	R3	Resistor 220Ω	K2
1*	D1	Red LED or high-brightness LED	K1 or S2
*		Solid-core jumper wire	T6
1		Push light	

* These components are only needed for the breadboard experiment.

We want the LDR to control an LED, so a first thought at a circuit might be as shown in Figure 3-12.

There are two fatal flaws in this design. First, as more light falls on the LDR its resistance decreases, allowing more current to flow so the LED will get brighter. This is the opposite of what we want. We want the LED to come on when it's dark.

We need to use a transistor.

The basic operation of a transistor is shown in Figure 3-13. There are many different types of transistors, and probably the most common (and the type we will use) is called an NPN bipolar transistor.

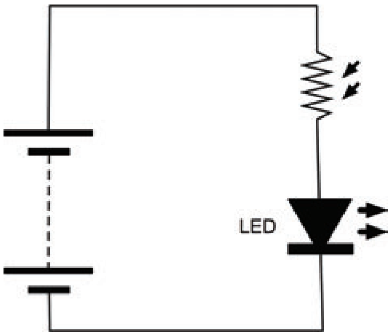

FIGURE 3-12 An LED and LDR

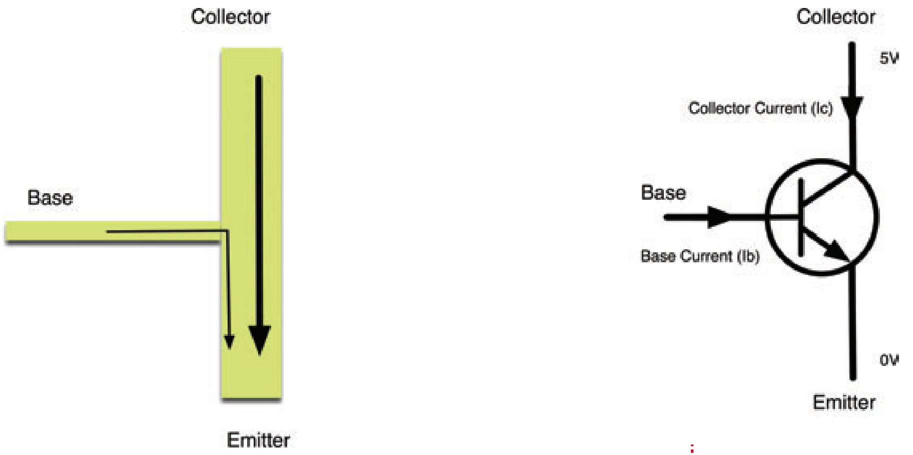

FIGURE 3-13 A bipolar transistor

This transistor has three leads: the emitter, the collector, and the base. The basic principal is that a small current flowing through the base will allow a much bigger current to flow between the collector and the emitter.

Just how much bigger the current is depends on the transistor, but it's typically a factor of 100.

Breadboard

Figure 3-14 shows the schematic diagram we will build on the breadboard. To understand this circuit, let's consider two cases.

Case 1: When It's Dark

In this case, the LDR R1 will have a very high resistance, so you could almost imagine that it isn't there at all. In that case, current will flow through R2, through the base and emitter of the transistor, allowing as much current as it needs to flow through R3, the LED, and T1 into its collector and out through the emitter. When enough current flows into the base of a transistor to allow current to flow from the collector to the emitter, this is called "turning on" the transistor.

We can calculate the base current using Ohm's law. In this situation, the base of the transistor will be at only about half a volt, so we can assume there is more or less the full 6V across the 10kΩ resistor R2. Since I = V / R, the current will be 6 / 10,000 A or 0.6mA.

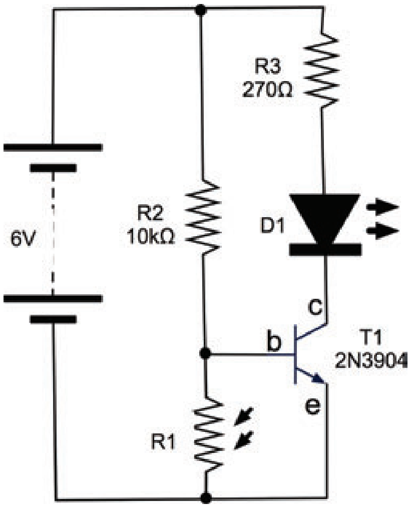

FIGURE 3-14 Using an LDR and transistor to switch an LED

Case 2: When It's Light

When it is light, we have to consider the resistance of the LDR R1. The lighter it is, the lower the resistance of R1 and the more of the current otherwise destined for the base of the transistor will be diverted through R1, preventing the transistor from turning on.

I think the time has come to build the project on breadboard. Figure 3-15 shows the breadboard layout, and Figures 3-16a and 3-16b the finished breadboard.

When placing the LED on the breadboard, make sure you get it the right way around. The longer lead is the positive lead, and it should be on row 10 connected to R3. (See Figure 3-16a.)

If everything is fine, you should find that when you cover the LDR, the LED should light (Figure 3-16b).

Construction

Now that we have proved our circuit works, we can get on with modding the push light. Figure 3-17 shows the push light the author used. Unless you are very lucky, yours is likely to be

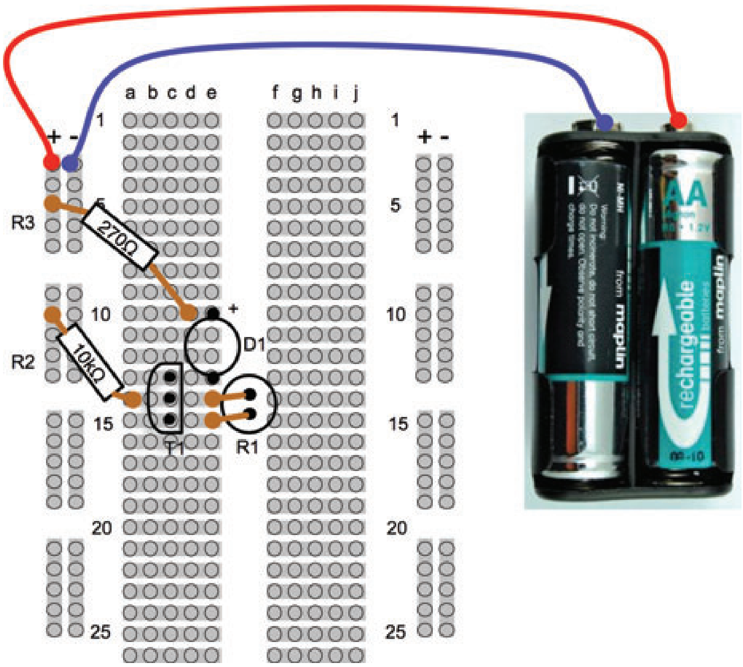

FIGURE 3-15 The light switch breadboard layout

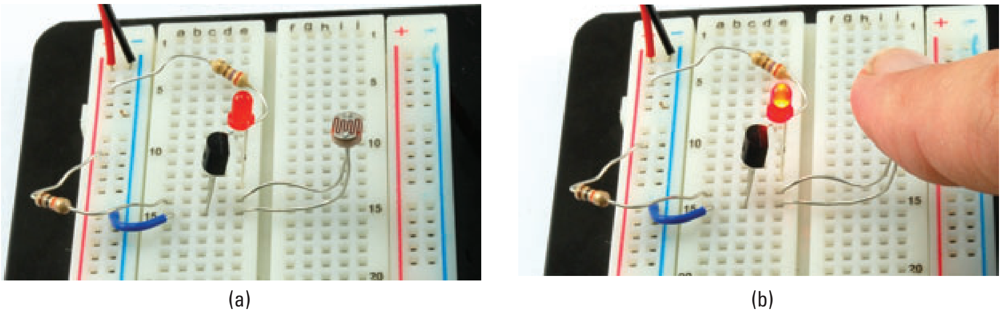

FIGURE 3-16 The light switch breadboard

different, so read through the following sections carefully and you should be able to work out how to change your light. To make life easy for yourself, try and find a push light that operates from 6V (4 AA or AAA cells).

You will probably find screws on the back of the push light. Remove these and put them somewhere safe. The inside of the push light is shown in Figure 3-18. The various connections on the light are marked. You can find the corresponding connections on your light using a multimeter.

Setting the multimeter to its 20V DC range will let you determine which battery lead is positive and which is negative. Looking at the wiring, we can draw a schematic diagram for the light as it stands, before we start altering it (Figure 3-19).

FIGURE 3-17 A push light

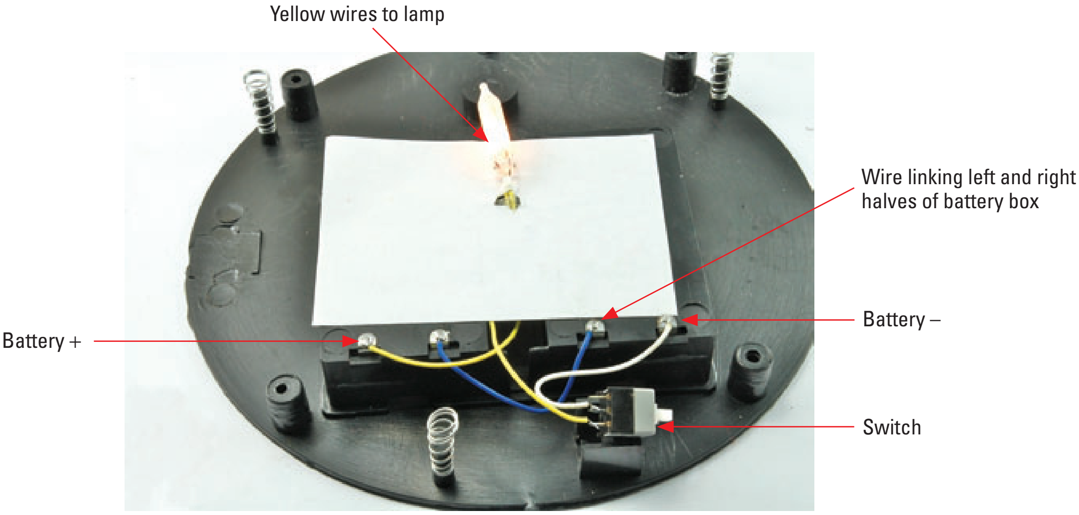

FIGURE 3-18 Inside the push light

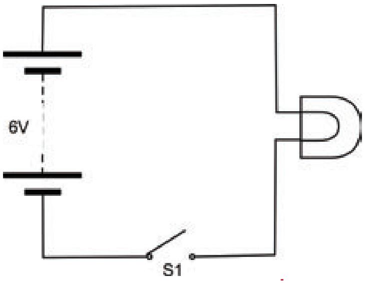

FIGURE 3-19 The schematic diagram for the original push light

This light uses an old-fashioned incandescent bulb. We will replace that with a high-brightness LED. If you don't have one of these, a regular LED of the color of your choice will work, but not be very bright.

Figure 3-20 shows how we replaced the bulb with the LED and the 220Ω resistor. Make sure the longer positive lead of the LED is connected to the resistor and the far side of that resistor is connected to the positive terminal of the battery.

Try pressing the switch to make sure the LED is working.

We can now draw a schematic that combines what we have in the existing lamp and our LDR circuit (Figure 3-21).

In fact, all this really amounts to is adding in the switch to the original LED schematic. We have already installed R3 and D1 when we replaced the bulb with an LED. The switch is already there, so all we need to add is the transistor, LDR, and R2. Figure 3-22 shows how we will rewire the push light.

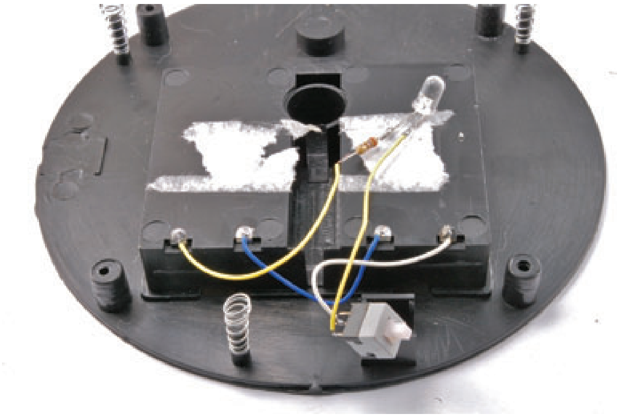

FIGURE 3-20 Replacing the bulb with an LED and a resistor

Figure 3-23 shows the sequence of steps in soldering the extra components onto the light.

1. Start by desoldering the lead from the switch that isn't connected to the negative battery terminal (Figure 3-23a).
2. Solder the 10kΩ resistor R2 between the middle lead of the transistor (the base) and the positive terminal on the battery box.
3. With the flat of the transistor facing upward, as shown in the diagram, connect the left-hand lead of the transistor to the wire you just disconnected from the switch (Figure 3-23b).
4. Solder the LDR between the left and middle pins of the transistor, and connect the combined left-hand transistor lead and LDR lead to the connection on the switch that the wire used to be attached to. (See Figure 3-23c.)
5. Tuck the components away neatly, bending the leads to make sure there is no way the bare leads can touch each other. (See Figure 3-23d.)

How to Choose a Bipolar Transistor

The transistor we used in the previous section, "Hack a Push Light to Make It Light Sensing," is a useful general-purpose transistor. But there are many other types of transistors that we can use for different purposes. This section is to help you find the right transistor and try to use it in such a way that it doesn't die in a puff of smoke.

Datasheets

Transistors have a number of parameters we need to know about. All transistors have an associated datasheet. This is produced by the manufacturer and specifies everything you could possibly want to know about the device, from the dimensions of its leads to its electrical characteristics.

Most of the time you will use one of three or four transistors and will not need to look into the exact details of how the transistor behaves, but if you do need to, it's there on the datasheet. So, you may just want to skip to the next subsection where we look at a few different types of transistors—just the useful ones, nothing exotic.

Table 3-1 shows some of the data you will find on the 2N3904's datasheet under maximum ratings.

Maximum Collector-Emitter and Collector-Base voltages of 40V and 60V mean we do not have to worry about exceeding them in battery-powered devices. We need to be careful that we do not exceed the emitter-base voltage though.

The maximum collector current of 200mA is quite healthy though. It means we could in theory control ten LEDs, all taking 20mA at the same time. If we do exceed this value, then the transistor will get hot and eventually fail.

The one electrical characteristic we are most interested in is DC current gain or h_{FE} as it will be called on the datasheet. This is listed in the electrical characteristics section of the datasheet.

You may remember that the DC gain is the multiplier that determines how much more current can flow in through the base than the collector. Looking at Table 3-2, this means that at a collector current of 10mA and a collector emitter voltage of 1.0V (it's

Absolute Maximum Ratings

Symbol	Parameter	Value	Units
V_{CEO}	Collector-Emitter Voltage	40	V
V_{CBO}	Collector-Base Voltage	60	V
V_{EBO}	Emitter-Base Voltage	6.0	V

TABLE 3-1 2N3904 Maximum Ratings

Symbol	Parameter	Test Condition	Min	Max	Units
ON CHARACTERISTICS					
h_{FE}	DC Current Gain	I_C = 0.1 mA, V_{CE} = 1.0V	40		
		I_C = 1.0 mA, V_{CE} = 1.0V	70		
		I_C = 10 mA, V_{CE} = 1.0V	100	300	
		I_C = 50 mA, V_{CE} = 1.0V	60		
		I_C = 100 mA, V_{CE} = 1.0V	30		

TABLE 3-2 2N3904 Electrical Characteristics

nearly always about that), the typical gain will be 100, meaning that only 10mA / 100 = 100nA needs to be flowing into the base for this amount of current to flow through the collector.

MOSFET Transistors

The 2N3904 is what is called a bipolar transistor. It's basically a device that amplifies current. A small current into the base controls a much bigger current flowing through the collector. Sometimes, the current gain of just 100 or so is not nearly enough.

There is another type of transistor that does not suffer from this limitation called the MOSFET (Metal Oxide Semiconductor Field Effect Transistor). You can see why it gets shortened to MOSFET. These transistors are controlled by voltage rather than current and make very good switches.

MOSFETs do not have emitters, bases, and collectors, they have "sources," "gates," and "drains." They turn on when the gate voltage passes a threshold, usually about 2V. Once on, quite large currents can flow through the "drain" to the "source" rather like a bipolar transistor. But since the gate is isolated from the rest of the transistor by a layer of insulating glass, hardly any current flows into the gate. It is the voltage at the gate that determines what current will flow.

We will meet MOSFETs again later in the section "How to Use a Power MOSFET to Control a Motor," and in Chapter 7 in the section "How to Control Motor Speed with a Power MOSFET."

PNP and N-Channel Transistors

The automated light switch of the previous section switched on the "negative side of the load." That is, if you go back to Figure 3-21, you can see that the resistor and LED that make up the light are not connected to GND except through the

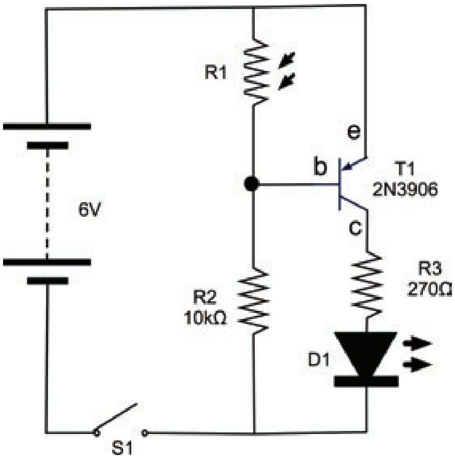

Figure 3-24 Using a PNP bipolar transistor

transistor. If for some reason (and this does happen) we wanted to switch the positive side, then we would need to use a PNP equivalent of the NPN 2N3904, such as the 2N3906. NPN stands for Negative-Positive-Negative, and yes, you can guess what PNP stands for. That is because transistors are kind of semiconductor sandwiches, with material of either N or P type as the bread. If the bread is N type (the most common), then the base voltage needs to be higher than the emitter voltage (by about 0.5V) before the transistor starts to turn on. On the other hand, a PNP transistor turns on when the base voltage is more than 0.5V lower than the emitter voltage.

If we wanted to switch the positive side, we could use a PNP transistor (as shown in the PNP alternative to Figure 3-21) displayed in Figure 3-24.

MOSFETs also have their own equivalent of PNP transistors called P-channel, their version of the more common NPN being called N-channel.

Common Transistors

The transistors in Table 3-3 will cover a wide range of transistor applications. There are thousands and thousands of other transistors, but in this book we only really use them for switching, so these will cover most "bases"!

Name	Appendix Code	Type	Max Switching Current	Notes
Low/medium-current switching				
2N3904	S1	NPN bipolar	200mA	Current gain about 100
2N3906	S4	PNP bipolar	200mA	Current gain about 100
2N7000	S3	N-channel MOSFET	200mA	2.1V gate-source threshold voltage; turns on when gate is 2.1V higher than source
High-current switching

TABLE 3-3 Really Useful Transistors

How to Use a Power MOSFET to Control a Motor

Figure 3-25 shows the schematic symbol and the pinout for the FQP30N06 N-channel MOSFET.

This MOSFET is capable of controlling loads of up to 30A. We are not going to push it any way near that far, we are just going to use it to control the power to a small electric motor that might have a peak load of 1 or 2A. While this would be too much for the bipolar transistors that we have been using so far, this MOSFET will hardly notice!

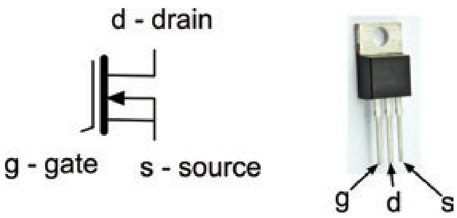

Figure 3-25 The FQP30N06 N-channel MOSFET

You Will Need

To try out this high-power MOSFET, you will need the following items.

Quantity	Item	Appendix Code
1	Solderless breadboard	T5
	Solid-core jumper wire	T6
1	4 × AA battery holder	H1
1	4 × AA batteries	
1	Battery clip	H2
1	Multimeter	T2
1	10kΩ trimpot	K1
1	FQP30N06 MOSFET	S6
1	6V DC motor or gear motor	H6

The DC motor can be any small motor you can find that is around 6V. A motor rated at 12V should still turn at 6V. To test it, just connect its terminals directly to the 6V battery.

Breadboard

The schematic diagram for what we will make is shown in Figure 3-26.

The variable resistor will control the voltage at the gate of the MOSFET. When that gate voltage exceeds the gate threshold, the transistor will turn on and the motor will start.

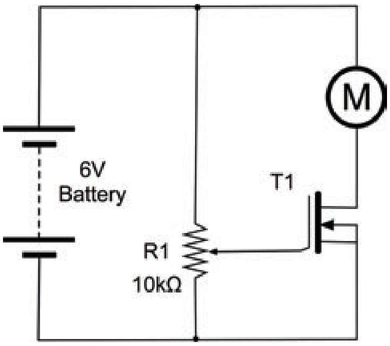

Figure 3-26 A schematic for the MOSFET experiment

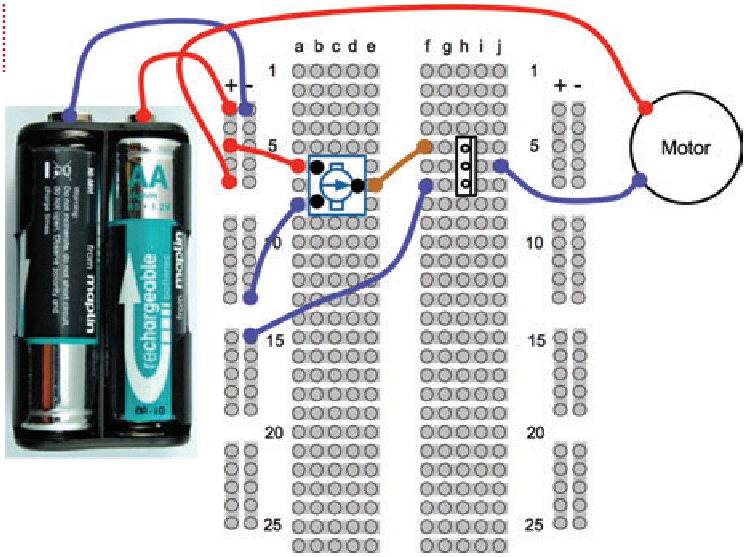
Figure 3-27 The breadboard layout for the MOSFET experiment

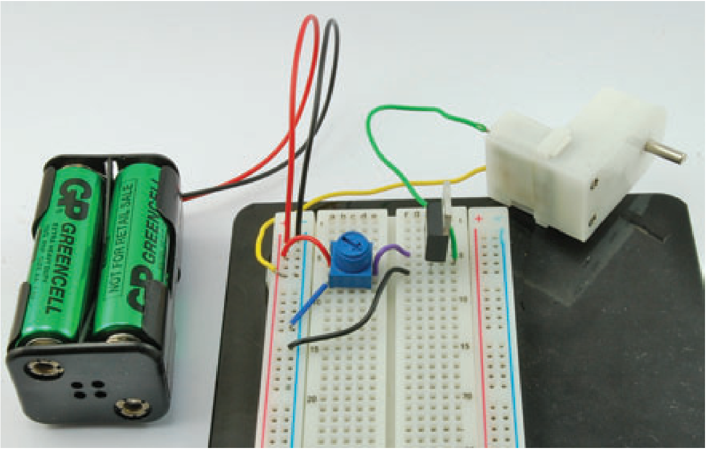


The breadboard layout for the project and a photograph of the experiment in action are shown in Figure 3-27 and Figure 3-28.

To connect the motor to the breadboard, you will probably need to solder a pair of leads to it. It does not matter which way around you connect the motor. The polarity just determines which direction the motor turns. So if you swap the motor leads over, it will turn in the opposite direction.

Try turning the knob on the variable resistor. You will see that you do not have a great deal of control over the speed of

Figure 3-28 The MOSFET experiment



the motor. If you hover around the threshold voltage, you can control the motor speed, but you can probably see why the MOSFET is most commonly used as a switch that is either on or off.

This kind of MOSFET is called a logic level MOSFET, because its gate voltage is low enough to be controlled directly by digital output pins on a microcontroller. This is not true of all MOSFETs. Some have gate threshold voltages of 6V or more.

In Chapter 7, you will use a MOSFET to finely control the motor speed.

How to Select the Right Switch

On the face of it, a switch is a very simple thing. It closes two contacts, making a connection. Often, that is all you need, but other times you will require something more complicated. For example, let's say you want to switch two things at the same time.

There are also switches that only make the contact while you are pressing them, or ones that latch in one position. Switches may be push button, toggle, or rotary. There are many options to choose from and in this section we will attempt to explain the options.

Figure 3-29 shows a selection of switches.

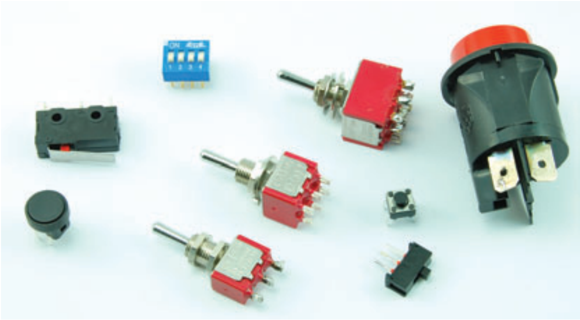


FIGURE 3-29 Switches

Push-Button Switches

Where so many things use a microcontroller, a simple push switch is probably the most common type of switch (Figure 3-30).

This kind of switch is designed to be soldered directly onto a circuit board. It will also fit onto our breadboard, which makes it quite handy.

The confusing thing about this switch is that it has four connections where you would only expect there to be two. Looking at Figure 3-30, you can see that connections B and C are always connected together, as are A and D. However, when the button is pressed, all four pins are all connected together.

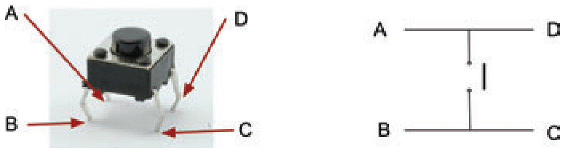

FIGURE 3-30 A push switch

This does mean that you need to be careful to find the right pins or your switch will be connected all the time.

If there is any doubt about how the switch works, use your multimeter set to Continuity mode to work out what is connected to what—first without the switch pressed and then with the switch pressed.

Microswitches

A microswitch is another type of handy switch. They are not designed to be pressed directly, but are often used in things like microwave ovens to detect that the door is closed, or as anti-tamper switches that detect when the cover is removed from an intruder alarm box.

Figure 3-31 shows a microswitch—with three pins!

The reason a microswitch has three pins rather than just two is that it is what is known as a "double throw" or "change-over" switch. In other words, there is one common connection C and two other connections. The common connection will always be connected to one of those contacts, but never both at the same time. The normally open (n.o.) connection is only closed when the button is pressed; however, the normally closed (n.c.) connection is normally closed, and only opens when the button is released.

If you have one of these switches, you might like to connect your multimeter to it. Attach one lead to the common connection and use it to find the n.c. connection, then press the button and the beep should stop.

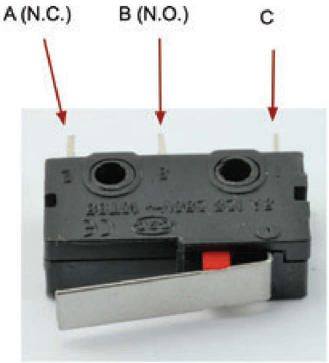

FIGURE 3-31 A microswitch

Toggle Switches

If you look through a component catalog (which every good electronics hacker should), you will find a bewildering array of toggle switches. Some will be described as DPDT, SPDT, SPST, or SPST, momentary on, and so forth.

Let's untangle some of this jargon, with a key for these cryptic letters:

- D = Double
- S = Single
- P = Pole
- T = Throw

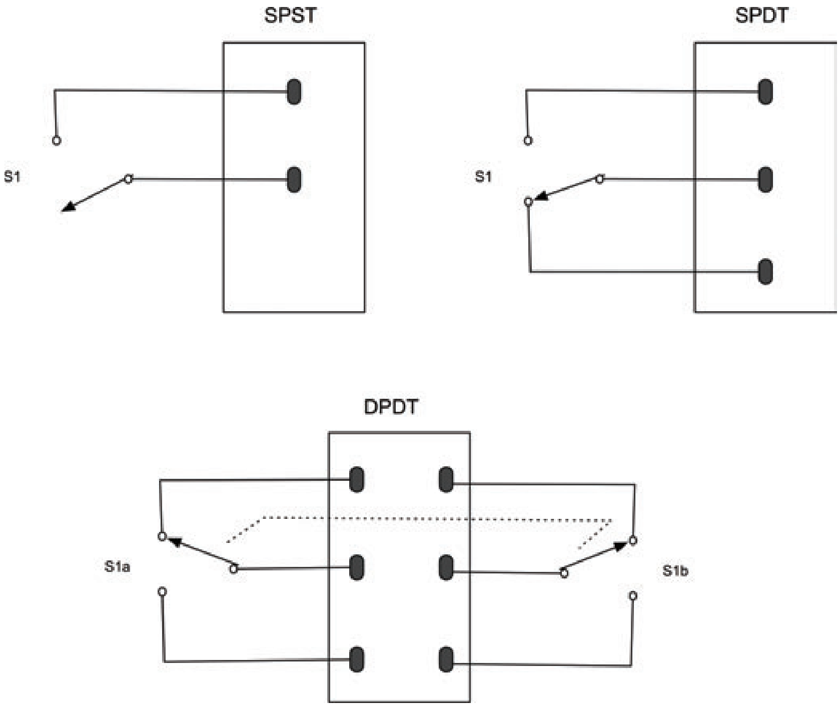
So, a DPDT switch is double pole, double throw. The word "pole" refers to the number of separate switch contacts that are controlled from the one mechanical lever. So, a double pole switch can switch two things on and off independently. A single throw switch can only open or close a contact (or two contacts if it is double pole). However, a double throw switch can make the common contact be connected to one of two other contacts. So, a microswitch is a double throw switch because it has both normally closed and normally open contacts.

Figure 3-32 summarizes this.

Notice in Figure 3-32 that when drawing a schematic with a double pole switch, it is normal to draw the switch as two switches (S1a and S1b) and connect them with a dotted line to show they are linked mechanically.

The matter is further complicated because you can have three poles or even more on a switch, and double throw switches are sometimes sprung, so they do not stay in one or both of these positions. They may also have a center-off position where the common contact is not connected to anything.

FIGURE 3-32 Toggle switches—poles and throws



You might see a switch described as "DPDT, On-Off-Mom." Well, we know what the DPDT bit means. It will have six legs for a start. The "On-Off-Mom" part means that it also has a center position, where the common connection is not made to anything. Switch it one way and it will be on to one set of contacts and stay in that position. Switch it the other way and it will be sprung to return to the central position, allowing you to make a "momentary" connection.

A lot of this terminology applies to other kinds of switches in addition to toggle switches.

Summary

We now know a bit about voltage, current resistance, and power. In the next chapter, we will use these ideas in looking at how to use LEDs.

LEDs

LEDs (light-emitting diodes) are diodes that emit light when a current passes through them. Well on the way to completely replacing filament light bulbs in almost all applications, they can be used as indicators and, with the very high brightness types of LED, can provide illumination.

They are much more efficient than conventional light bulbs, producing far more light per watt of power, and are a lot less delicate.

LEDs do, however, require a little more thought when used. They have to be powered with the correct polarity and require circuitry to limit the current flowing through them.

How to Stop an LED from Burning Out

LEDs are delicate little things and quite easy to destroy accidentally. One of the quickest ways of destroying an LED is to attach it to a battery without using a resistor to limit the current.

To get to grips with LEDs, we will put three different color LEDs on our breadboard (Figure 4-1).

You Will Need

Quantity	Names	Item	Appendix Code
1		Solderless breadboard	T5
1	D1	Red LED	K1
1	D2	Yellow LED	K1
1	D3	Green LED	K1
1	R1	330Ω resistor	K2
2	R2, R3	220Ω resistor	K2
		Jumper wires	T6
1		4 × AA battery holder	H1
1		Battery clip	H2
4		AA batteries	

Diodes

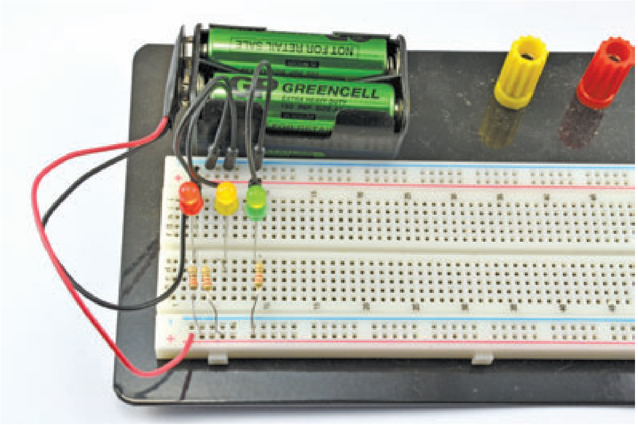

Figure 4-1 LEDs on a breadboard

We need to understand LEDs a little better if we are to successfully use them. LED stands for light-emitting diode, so let's start by looking at what a diode is (Figure 4-2).

A diode is a component that only lets current flow in one direction. It has two leads, one called the anode, and the other called the cathode. If the anode is at a higher voltage than the cathode (it has to be greater by about half a volt), then it will conduct electricity and is said to be "forward-biased." If on the other hand the anode isn't at least half a volt higher than the cathode, it is said to be "reverse-biased" and no current flows.

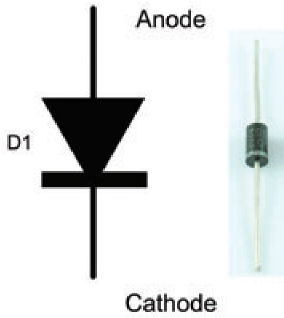

Figure 4-2 A diode

LEDs

An LED is just like a regular diode except that when it is forward-biased, it conducts and generates light. It also differs from a regular diode in that the anode usually needs to be at least 2V higher than the cathode for it to be forward-biased.

Figure 4-3 shows the schematic diagram for driving an LED.

The key to this circuit is to use a resistor to limit the current flowing through the LED. A normal red LED will typically just be lit at about 5mA and is designed to be used at around 10 to 20mA (this is called the "forward current" or I_F). We will aim for 15mA for our LED. We can also assume that when it is conducting, there will be about 2V across it. This is called the "forward voltage" or V_F. That means there will be 6 – 2 = 4V across the resistor.

So, we have a resistor that has a current flowing through it (and the LED) of 15mA and a voltage across it of 4V. We can use Ohm's law to calculate the value of resistance we need to achieve this:

$$R = V / I = 4V / 0.015A = 267\Omega$$

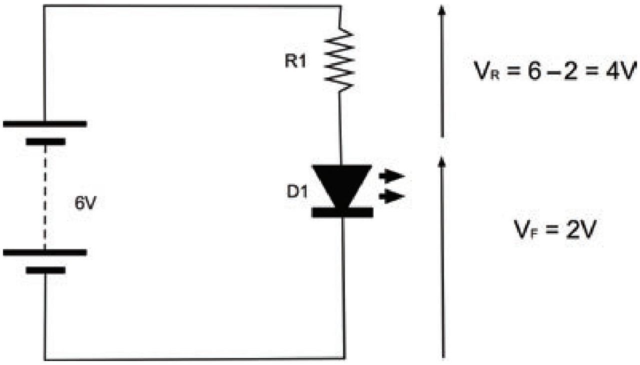

Figure 4-3 Limiting current to an LED

Parameter	Red	Green	Yellow	Orange	Blue	Units
Maximum forward current (I_F)	25	25	25	25	30	mA
Typical forward voltage (V_F)	1.7	2.1	2.1	2.1	3.6	V
Maximum forward voltage	2	3	3	3	4	V
Maximum reverse voltage	3	5	5	5	5	V

TABLE 4-1 An LED Datasheet

Resistors come in standard values, and the nearest higher value in our resistor starter kit is 330Ω.

As I mentioned earlier, a red LED will almost always light quite brightly with something like 10–20mA. The exact current is not critical. It needs to be high enough to make the LED light, but not exceed the maximum forward current of the LED (for a small red LED, typically 25mA).

Table 4-1 shows a section of the datasheet for a typical range of LEDs of different colors. Note how V_F changes for different color LEDs. This will mean you may need to use a different resistor, but usually if the supply voltage is above say 6V, then small variations in V_F for color will not require a different resistor value.

The other parameter you should be aware of is the "maximum reverse voltage." If you exceed this by, say, wiring your LED the wrong way around, it is likely to break the LED.

Many online series resistor calculators are available that—given the supply voltage V_F and current I_F for your LED—will calculate the series resistor for you. For example:

www.electronics2000.co.uk/calc/led-series-resistor-calculator.php

Table 4-2 is a useful rough guide, assuming a forward current of around 15mA.

Supply Voltage (V)	Red	Green, Yellow, Orange	Blue
3	91Ω	60Ω	none
5	220Ω	180Ω	91Ω
6	270Ω / 330Ω	220Ω	180Ω

Figure 4-4 An LED's schematic

Trying It Out

You might like to try out your LEDs and get them lit up on the breadboard. So, using Figures 4-4 and 4-5 as a guide, wire up your breadboard. Remember that the longer lead of the LED is normally the anode (positive) and thus should be to the left of the breadboard.

An important point to notice here is that each LED has its own series resistor. It is tempting to use one lower value current limiting resistor and put the LEDs in parallel, but don't do this. If you do, the LED with the lowest V_F will hog all the current and probably burn out, at which point the LED with the next lowest V_F will do the same, until all the LEDs are dead.

How to Select the Right LED for the Job

LEDs come in all colors, shapes, and sizes. Many times, you just want a little indicator light, in which case a standard red LED is usually fine. However, there are many other options, including LEDs bright enough to be used as lamps.

You Will Need

Quantity	Names	Item	Appendix Code
1		Solderless breadboard	T5
1	D1	RGB common cathode LED	S4
3	R1–R3	500Ω trimpot	R3
1	R1	330Ω resistor	K2
2	R2, R3	220Ω resistor	K2
		Jumper wires	T6
1		4 × AA battery holder	H1
1		Battery clip	H2
4		AA batteries	

Brightness and Angle

When selecting an LED, they may simply be described as “standard” or “high brightness” or “ultra-bright.” These terms are subjective and open to abuse by unscrupulous vendors. What you really want to know is the LED’s luminous intensity, which is how much light the LED produces. You also want to know the angle over which the LED spreads the light.

So, for a flashlight, you would use LEDs with a high luminous intensity and a narrow angle. Whereas for an indicator light to show that your gadget is turned on, you would probably use an LED with a lower luminous intensity but a wider angle.

Luminous intensity is measured in millicandela or mcd, and a standard indicator type LED will typically be around 10 to 100 mcd, with a fairly wide viewing angle being 50 degrees. A “high brightness” LED might be up to 2000 or 3000 mcd, and an ultra-bright anything up to 20,000 mcd. A narrow beam LED is about 20 degrees.

Multicolor

We have already explored the more common LED colors, but you can also get LED packages that actually contain two or three LEDs of different colors in the same package. Common varieties are red/green as well as full-color RGB (Red Green Blue). By varying the proportion of each color, you can change the color of the light produced by the LED package.

Figure 4-6 shows the schematic we can use to try out a little experiment with an RGB LED.

We are going to use a variable resistor with each of the red, green, and blue LEDs. The fixed resistors (R4, R5, and R6) are to prevent too much current flowing when the slider of the variable resistor is right at 6V.

Figure 4-7 shows the breadboard layout for this. The common lead of the LED is the longest lead, while the other three are the three-color anodes.

Once all the components are in the board and you have attached the battery, you should be able to mix various colors by changing the position of the three sliders. Figure 4-8 shows the circuit in operation.

IR and UV

As well as visible LEDs, you can also buy LEDs whose light is invisible. This is not as pointless as you might think. Infrared LEDs are used in TV remote controls, and ultraviolet LEDs are

Figure 4-6 An RGB LED test schematic

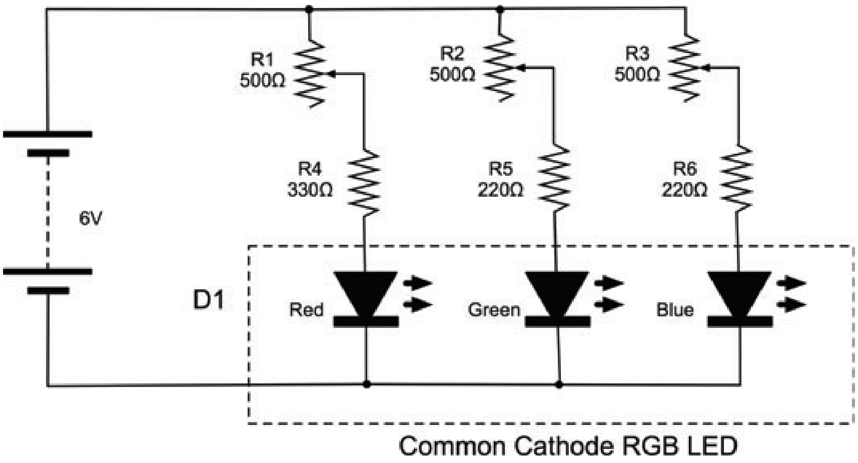

FIGURE 4-7 An RGB LED test breadboard layout

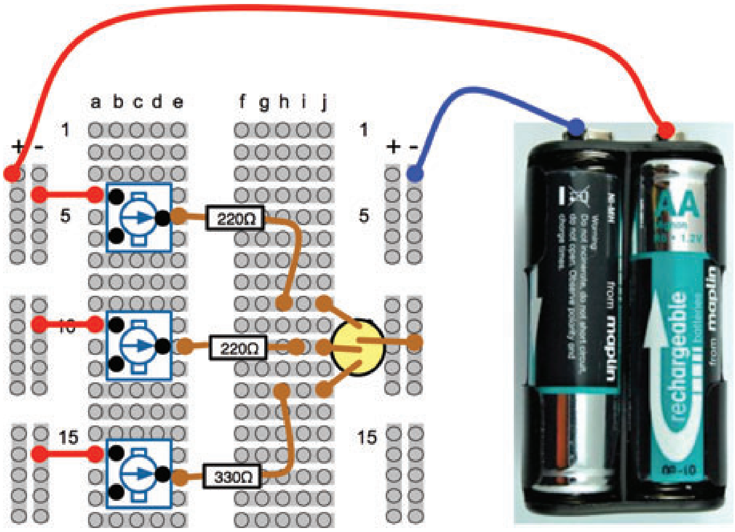
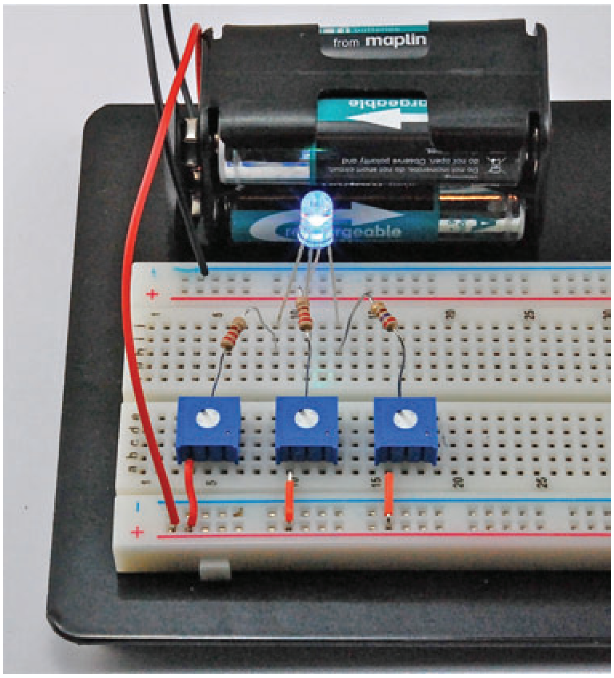


used in specialist applications such as checking the authenticity of bank notes and making people's white clothes light up in clubs.

FIGURE 4-8 An RGB test



Use these LEDs just like any other LED. They will have a recommended forward current and voltage and will need a series resistor. Of course, checking that they are working is trickier. Digital cameras are often a little sensitive to infrared and you may see a red glow on the screen.

LEDs for Illumination

LEDs are also finding their way into general household lighting. This has come about because of improvements in LED technology that have produced LEDs with a brightness comparable to incandescent light bulbs—well, they are getting there anyway. Figure 4-9 shows one such high-brightness LED. In this case, it's a 1-W LED, although 3-W and 5-W LED modules are also available.

The cool-looking star shape is thanks to the aluminum heat sink that the LED is attached to. At full power, these LEDs produce enough heat to warrant such a heat sink to disperse the heat into the air.

These LEDs can use a resistor to limit the current, but a quick calculation will show you that you will need quite a high-power resistor. A better approach to using these LEDs is to use a constant current driver, which is the subject of the next section.

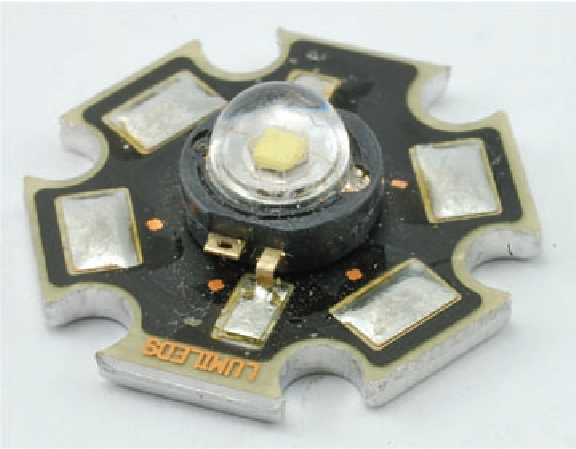


Figure 4-9 A high-power LED

How to Use a LM317 to Make a Constant Current Driver

Using a resistor to limit the current is all right for small LEDs. However, it is a bit hit or miss since it is very dependent on the LED being used and the power being provided. So for low-power LEDs, where the supply current is not critical it works okay. For high-power LEDs, you can use a series resistor (it will need to be quite high power), but a better way is to use a constant current driver.

As the name suggests, the constant current driver will supply the same current whatever voltage it is supplied with and whatever the forward voltage of the LED. You just set the current and that is how much current will flow through the high-power LED.

A very useful IC that is often used for this purpose is the LM317. This IC is primarily intended as an adjustable voltage regulator, but can easily be adapted for use in regulating current.

This project will start off on breadboard and then we will cut the top off a battery clip and solder the LM317 and resistor to it to make an emergency 1-W LED light.

You Will Need

Quantity	Names	Item	Appendix Code
1		Solderless breadboard	T5
1	D1	1-W white Lumileds LED	S3

Quantity	Names	Item	Appendix Code
3	R1	4.7Ω resistor	K2
1		Battery clip (to destroy)	H2
1		PP3 9V battery	
		Jumper wires	T6

Design

Figure 4-10 shows the schematic diagram for regulating the current to a high-power LED like the one shown in Figure 4-9.

The LM317 is very easy to use in a constant current mode. It will always strive to keep its output voltage at exactly 1.25V above whatever voltage the Adj (adjust) pin is at.

The LED we are going to use is a 1W white light LED. It has an I_f (forward current) of 300mA and a V_f (forward voltage) of 3.4V.

The formula for calculating the right value for R1 for use with the LM317 is:

$$R = 1.25V / I$$

so in this case, R = 1.25 / 0.3 = 4.2Ω

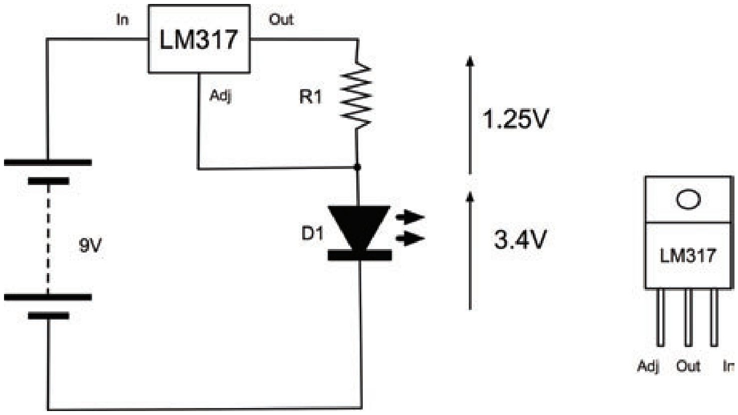
If we used a standard resistor value of 4.7Ω, then this would reduce the current to:

$$I = 1.25V / 4.7\Omega = 266 \text{ mA}$$

Checking the power rating for the resistor, the LM317 will always have 1.25V between Out and Adj. So:

$$P = V \times I = 1.25V \times 266mA = 0.33W$$

Figure 4-10 An LM317 constant current LED driver schematic



A half-watt resistor will therefore be fine.

The LM317 also needs its input to be about 3V higher than its output to guarantee 1.25V between Adj and the output. This means that a 6V battery would not be quite high enough because the forward voltage is 3.4V. However, we could drive the circuit using a 9V battery or even a 12V power supply without modification, since whatever the input voltage, the current will always be limited to about 260mA.

A quick calculation of the power consumed by the LM317 will reassure us that we are not going to come near exceeding its maximum power rating.

For a 9V battery, the voltage between In and Out will be 9 – (1.25 + 3.4) = 4.35V. The current is 260mA, so the power is: 4.35 × 0.26 = 1.13W.

According to its data sheet, the maximum power handling capability of the LM317 is 20W, and it can cope with a current of up to 2.2A for a supply voltage of less than 15V. So we are fine.

Breadboard

Figure 4-11 shows the breadboard layout for this, and Figure 4-12 displays the actual breadboard. These LEDs are almost painfully bright, so avoid staring at them. When working with them, I cover them with a sheet of paper so I can see when they are on without being temporarily blinded!

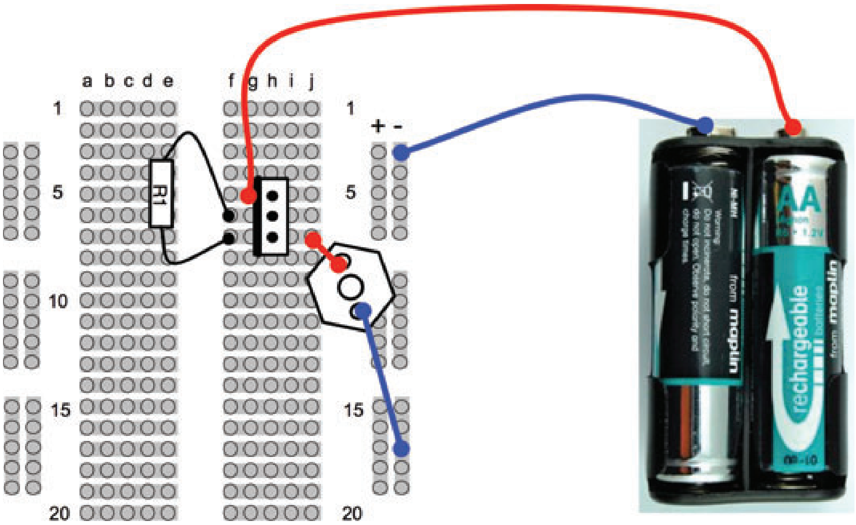


FIGURE 4-11 The LED constant current driver breadboard layout

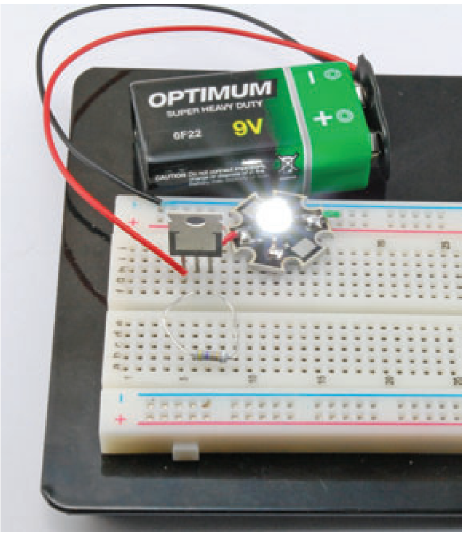

FIGURE 4-12 The LED constant current driver

You will need to solder lengths of solid-core wire to the LED's terminals so it can plug into the breadboard. It is a good idea to leave the insulation on so there is no chance of the bare wires touching the heat sink and shorting.

Construction

We will use this to make a little emergency lantern by hacking a battery clip to build the electronics on top of it so it can be clipped on top of a PP3 battery in the event of a power failure (Figure 4-13).

Figures 4-14a thru 4-14d shows the stages involved in soldering this up.

First, remove the plastic from the back of the battery clip using a craft knife. Then, unsolder the exposed leads (Figure 4-14a).

The next step (Figure 4-14b) is to solder the Input lead of the LM317 to the positive terminal of the battery clip. Remember that the positive connector on the clip will be the opposite of the connector on the battery itself, so the positive connector on the clip is the socket-shaped connector. Gently bend the leads of the LM317 apart a little to make this easier.

Now solder the LED in place making sure the cathode of the LED goes to the negative connection on the battery clip (Figure 4-14c).

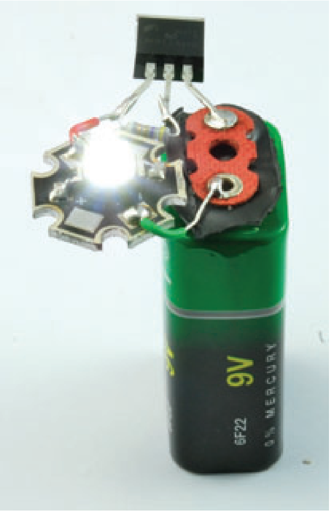

FIGURE 4-13 Emergency LED lighting

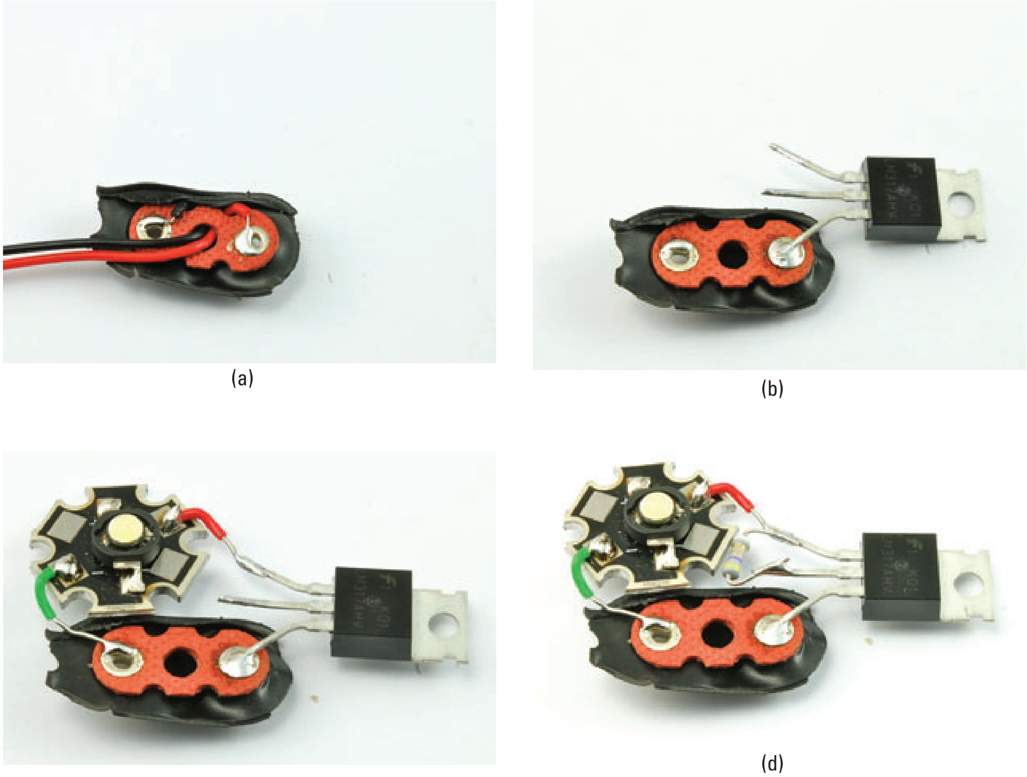

(a)

(b)

(c)

(d)

Figure 4-14 Making an emergency 1-W LED light

Finally, solder the resistor across the two topmost leads of the LM317 (Figure 4-14d).

How to Measure the Forward Voltage of an LED

If you want to power lots of LEDs at the same time, it is a good idea to test a few of the LEDs you actually intend to use and measure the forward voltage at the current you intend to use. Figure 4-15 shows how you would do this.

Figure 4-15a shows the schematic diagram. A variable resistor is used to vary the current through the LED and when the desired forward current is set, the voltage can be read.

The current and voltage do not have to be read at the same time, but if you do have two meters, this does make life easier.

Figure 4-15 Measuring the forward voltage of an LED

Set the variable resistor to its middle point and wire up the breadboard as shown in Figure 4-15b. You will probably have to move the positive lead of your multimeter to a different socket when measuring current. Select a current range of 200mA DC. Now adjust the variable resistor until the current reads 20mA.

We can now measure the voltage across the LED. To do this, first disconnect the multimeter, put the positive multimeter back in the right socket for measuring voltage, and then change the range to 20V DC. Wire it up as shown in Figure 4-15c and measure the voltage. In this case, it was 1.98V.

You Will Need

Quantity	Names	Item	Appendix Code
1		Solderless breadboard	T5
1	D1	LED	K1
3	R1	500Ω trimpot	R3
		Jumper wires	T6
1		4 × AA battery holder	H1
1		Battery clip	H2
4		AA batteries	

How to Power Large Numbers of LEDs

If you use something like a 12V power supply, you can put a number of LEDs in series, with just one LED. In fact, if you know the forward voltages fairly accurately, and the power supply is well regulated, you can get away without any series resistor at all.

So, if you have fairly standard LEDs that have a forward voltage of 2V, then you could just put six of them in series. However, it will not be terribly easy to predict how much current the LEDs will take.

A safer approach is to arrange the LEDs in parallel strings, each string having its own current-limiting resistor (Figure 4-16).

Although the math for this isn't too hard, there can be a fair bit of it, so you can save yourself a lot of time by using an online calculator like http://led.linear1.org/led.wiz (Figure 4-17).

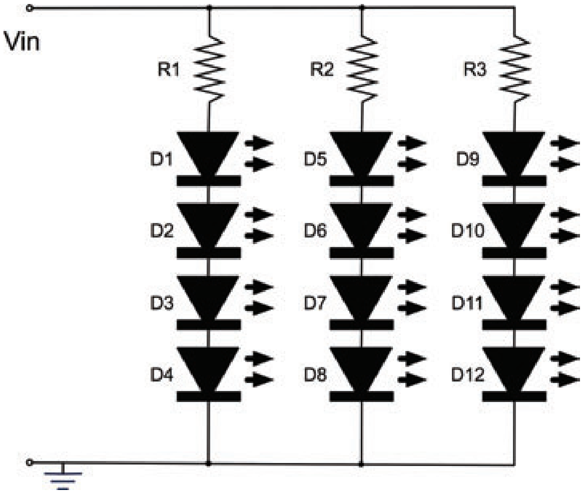

Figure 4-16 Powering multiple LEDs

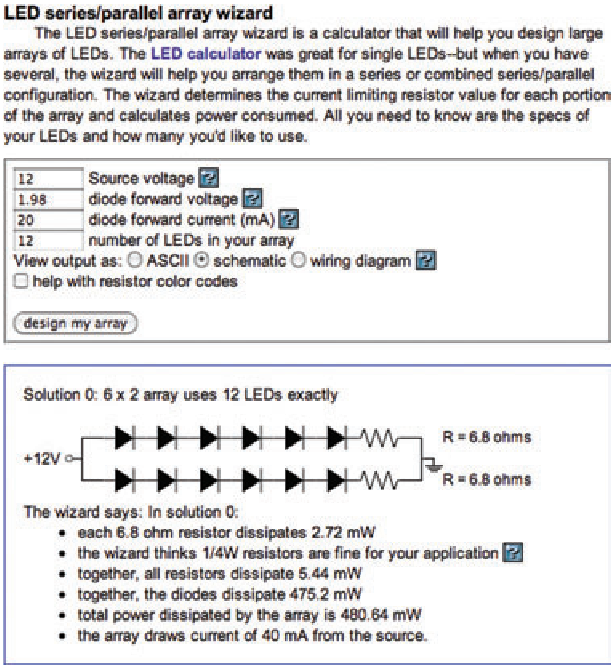

LED series/parallel array wizard

The LED series/parallel array wizard is a calculator that will help you design large arrays of LEDs. The LED calculator was great for single LEDs--but when you have several, the wizard will help you arrange them in a series or combined series/parallel configuration. The wizard determines the current limiting resistor value for each portion of the array and calculates power consumed. All you need to know are the specs of your LEDs and how many you'd like to use.

12	Source voltage
1.98	diode forward voltage
20	diode forward current (mA)
12	number of LEDs in your array

View output as: ○ ASCII ● schematic ○ wiring diagram

☐ help with resistor color codes

Solution 0: 6 x 2 array uses 12 LEDs exactly

The wizard says: In solution 0:

- each 6.8 ohm resistor dissipates 2.72 mW
- the wizard thinks 1/4W resistors are fine for your application
- together, all resistors dissipate 5.44 mW
- together, the diodes dissipate 475.2 mW
- total power dissipated by the array is 480.64 mW
- the array draws current of 40 mA from the source.

Figure 4-17 The LED wizard

In this particular designer, you enter the source voltage for the overall supply, the LED forward voltage, the desired current for each LED, and the number of LEDs you want to light. The wizard then does the math and works out a few different layouts.

One consideration is that where you have a string of LEDs in series, if any of the LEDs fail, then all the LEDs will be off.

How to Make LEDs Flash

The 555 timer IC is a useful little IC that can be used for many different purposes, but is particularly convenient for making LEDs flash or generating higher frequency oscillations suitable for making audible tones (see Chapter 9).

We are going to make this design on breadboard and then transfer it to a more permanent home on a bit of stripboard.

You Will Need

Quantity	Names	Item	Appendix Code
1		Solderless breadboard	T5
1	D1	LED red	K1
1	D1	LED green	K1
1	R1	1kΩ resistor	K2
1	R2	470kΩ resistor	K2
2	R3, R4	220Ω resistor	K2
1	C1	1µF capacitor	K2
1	IC1	555 timer	K2
		Jumper wires	T6
1		4 × AA battery holder	H1
1		Battery clip	H2
4		AA batteries	

Breadboard

The schematic for the LED flasher is shown in Figure 4-18.

The breadboard layout is shown in Figure 4-19. Make sure you have the IC the right way up. There will be a notch in the IC body next to the top (pins 1 and 8). The capacitor and LEDs must both be the correct way around, too.

Figure 4-20 shows the finished breadboard. You should find that the LEDs alternate, each staying on for about a second.

Now that we know the design is right and everything works, try swapping out R2 with a 100kΩ resistor and notice the effect on the flashing.

The 555 timer is a very versatile device, and in this configuration it oscillates at a frequency determined by the formula:

frequency = 1.44 / ([R1 + 2 * R2] * C)

where the units of R1, R2, and C1 are in Ω and F. Plugging in the values for this design, we get:

frequency = 1.44 / ([1000 + 2 * 470000] * 0.000001) = 1.53 Hz

One hertz (or Hz) means one oscillation per second. When we use the 555 timer in a later chapter to generate an audible tone, we will be using the same circuit to generate a frequency in the hundreds of hertz.

As with so many electronic calculations, there are also online calculators for the 555 timer.

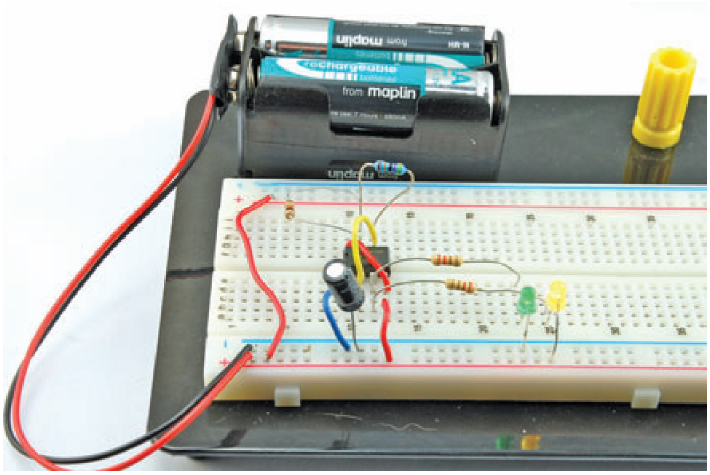
FIGURE 4-20 The LED flasher on breadboard



How to Use Stripboard (LED Flasher)

Breadboard is very useful for trying things out, but not so useful as a permanent home for your electronics. The problem is that the wires tend to fall out, and it's all a bit big and bulky.

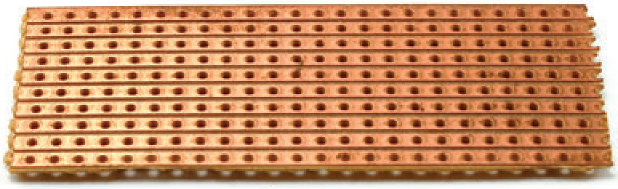


FIGURE 4-21 Stripboard

Stripboard (Figure 4-21) is a bit like general-purpose printed circuit board. It is a perforated board with conductive strips running underneath, rather like breadboard. The board can be cut to the size you need and components and wires soldered onto it.

Designing the Stripboard Layout

Figure 4-22 shows the final stripboard layout for the LED flasher that we made in the previous section. It is not easy to explain how we got to this from the schematic and breadboard layout. There is a certain amount of trial and error, but there are a few principals you can follow to try and make it easier.

The first is to use a drawing tool with a stripboard template. For Mac users, with OmniGraffle, a template is available for download from the book's web site (www.hackingelectronics.com). There is also an image file that can be printed out and used as a template to sketch out the design.

The Xs underneath the IC are breaks in the track, which we will make with a drill bit. One of the goals of a good stripboard

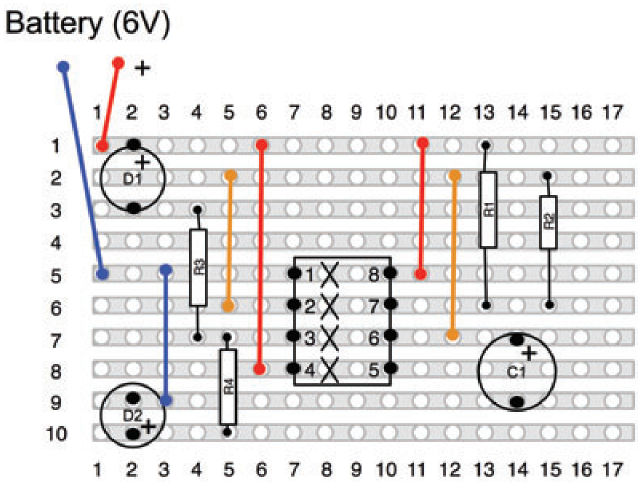

FIGURE 3-22 An LED flasher stripboard layout

layout is to try and avoid making too many breaks in the track. Breaks are unavoidable for an IC like this. If we did not make them, pin 1 would be connected to pin 8, pin 2 to pin 7, and so on, and nothing would work.

The colored lines on the board are linking wires. So, for instance, from the schematic diagram of Figure 4-18, we can see that pins 4 and 8 of the IC should be connected together and both go to the positive supply. This is accomplished by the two red linking wires. Similarly, pins 2 and 6 need to be connected together. This is accomplished by using the orange leads.

Although logically the stripboard layout is the same as the schematic, the components are in rather different places. The LEDs are on the left in the stripboard layout and on the right on the schematic. It is not always like this, and it's easier if they are similar, but in this case the left-hand pins of the IC include the output pin 3 that the LEDs need, and the pins connected to R1, R3, and C1 are all on the right-hand side of the IC.

Try making a stripboard layout from the schematic, you may well come up with a different and better layout than the one I produced.

The steps I went through in designing this layout are as follows:

1. Place the IC fairly centrally, with a bit more room above than below and with pin 1 uppermost (convention).
2. Find a good place for R3 and R4 to be put so the strips are at least three holes apart for one resistor lead, when the other lead of each resistor goes to pin 3.

3. Pick the top track of the stripboard to be +V so it can be close to the positive end of one of the LEDs
4. Pick row 5 to be the ground connection. This way it can run straight on to pin 1 of the IC.
5. Add a link wire from row 5 to row 9 to provide the negative connection for the LED D2.
6. Put a jumper wire from pin 4 of the IC to row 1 (+V).

Turning now to the right-hand side of the board:

1. Put a jumper in connecting pin 8 of the IC to row 1 (+V).
2. R1 and R2 both have one end connected to pin 7, so put them side by side with the far end of R1 going to row 1 (+V).
3. R2 needs to connect to pin 6, but pin 6 and pin 7 of the IC are too close together for the resistor to lie flat, so take that lead up to the unused row 2 instead, then put jumpers from row 2 down to both pin 6 and pin 2 of the IC.
4. Finally, C1 needs to go between pin 6 (or pin 2, but 6 is easier) and GND (row 9).

A good way of checking that you have made all the connections you need is to print off the schematic and then go through each connection on the stripboard and check off its counterpart on the schematic.

This may all seem a little like magic, but try it. It's not as hard to do as it is to describe.

You Will Need

You will need all the components listed in the section "How to Make LEDs Flash," plus the following items.

Quantity	Item	Appendix Code
1	Stripboard 10 strips by 17 holes	H3
1	Soldering kit	T1
1	Drill bit (1/8 inch)	

Before we start soldering, it is worth considering what kind of LEDs you want to use for this project. You may decide to use higher-brightness LEDs or power the project from a lower voltage. If you do decide on this, recalculate the values for R3 and R4 and try it out on the breadboard layout. The 555 timer IC needs a supply voltage between 4.5V and 16V, and the output can supply up to 200mA.

Construction

Step 1. Cut the Stripboard to Size

There is no point in having a large bit of stripboard with just a few components on it, so the first thing we need to do is cut the stripboard to the right size. In this case, it's ten strips each of 17 holes. Stripboard doesn't actually cut very well. You can use a rotary tool, but wear a mask because the dust from the stripboard is nasty and you really do not want it in your lungs. I find the easiest way to cut stripboard is actually to score it with a craft knife and metal ruler on both sides and then break it over the edge of your work surface.

Score it across the holes, not between them. When the board is cut, the copper underside will look like Figure 4-23.

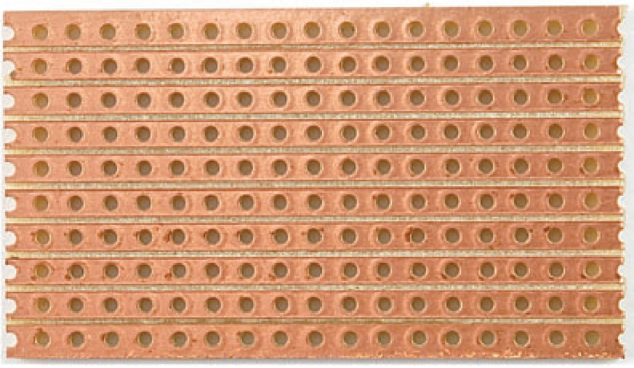

Figure 4-23 A stripboard cut to size

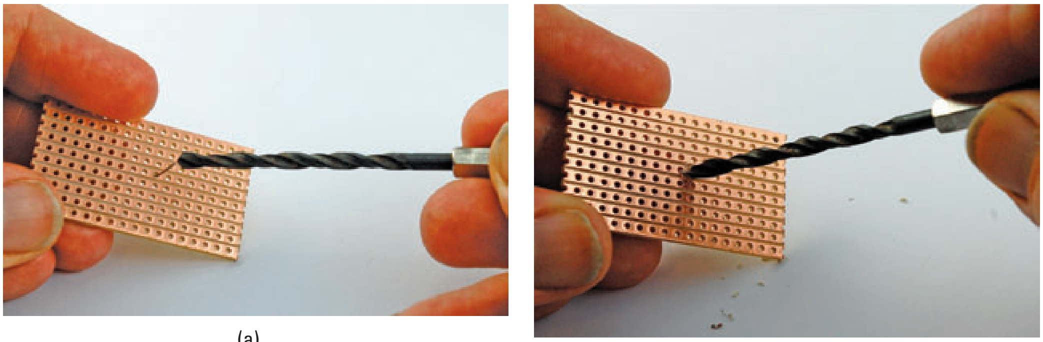
Step 2. Make the Breaks in the Tracks

A good tip is to use a permanent marker and put a dot in the top left corner. Otherwise, it is very easy to get the board turned around, resulting in breaks and links being put in the wrong place.

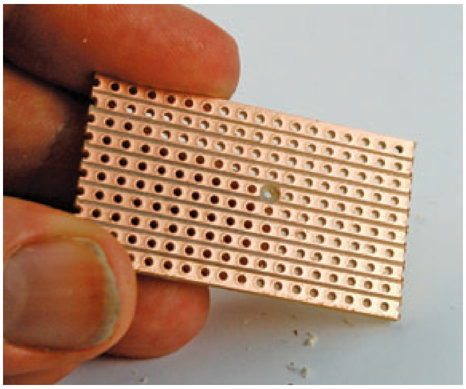
To make the breaks, count the position in rows and columns of the break from the top of the board layout and then push a bit of wire so you can identify the right hole on the copper side of the stripboard (Figure 4-24a). Using a drill bit, just "twizzle" it between thumb and forefinger to cut through the copper track. It usually only takes a couple of twists (Figure 4-24b and c).

When you have cut all four breaks, the bottom side of the breadboard should look like Figure 4-25. Check very carefully that none of the burrs from the copper have lodged between the tracks and that the breaks are complete. Photographing the board and then zooming in is a great way of actually checking the board.



(a)

(b)



(c)

FIGURE 4-24 Cutting a track on stripboard

Step 3. Make the Wire Links

A golden rule of any type of circuit board construction, including when using stripboard, is to start with the lowest-lying components. This is so that when you turn the board on its back to solder it, the thing being soldered will stay in place through the weight of the board.

In this case, the first thing to solder is the links.

Strip and cut solid-core wire to slightly longer than the length of the link. Bend it into a U-shape and push it through the holes at the top, counting the rows and columns to get the right holes (Figure 4-26a). Some people get very skilled at bending the wires with pliers to just the right length. I find it easier to bend the wires with a bit of a curve so they will kind of squash into the right holes. I find this easier than trying to get the length just right from the start.

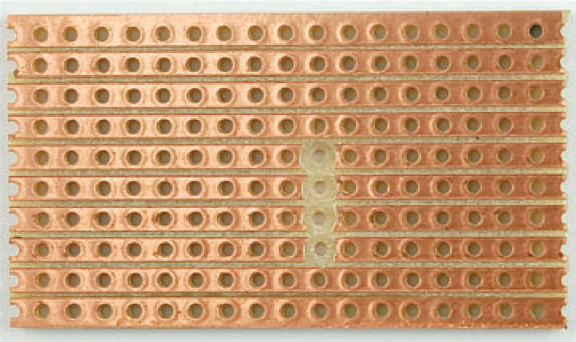


FIGURE 4-25 The stripboard with breaks cut

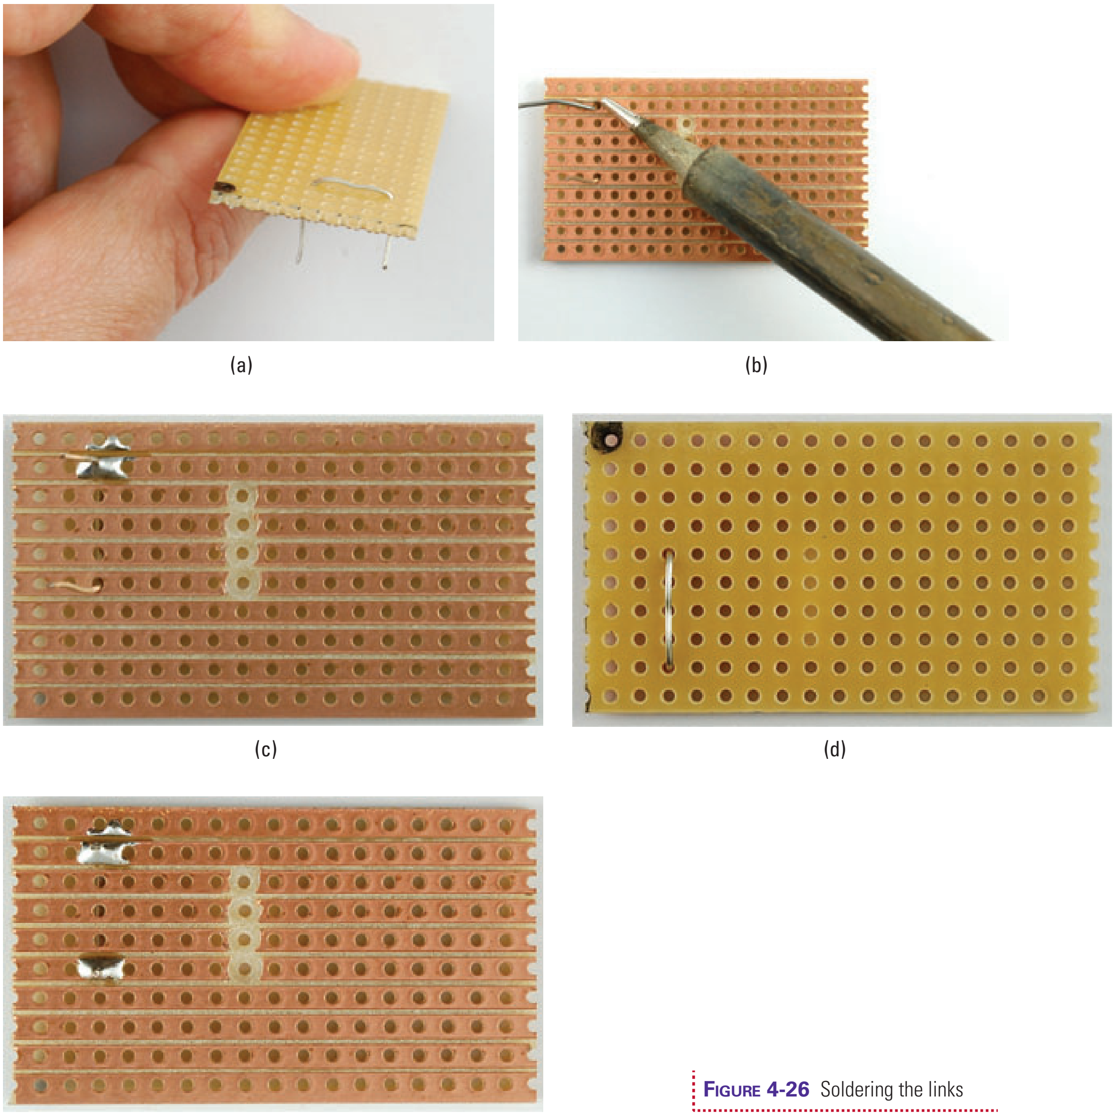
Turn the board over (see how the wire is held in place) and solder the wire by holding the iron to the point where the wire emerges from the hole. Heat it for a second or two and then apply the solder until it slows along the track, covering the hole and wire (Figure 4-26b and c).

Repeat this process for the other end of the lead and then snip off the excess wire (Figure 4-26d and e).

When you have soldered all the links, your board should look like the one in Figure 4-27.



(a)

(b)

(c)

(d)

(e)

Figure 4-26 Soldering the links

Step 4. Resistors

The resistors are the next lowest components to the board, so solder these next, in the same way as you did the links. When they are all soldered, the stripboard should look like Figure 4-28.

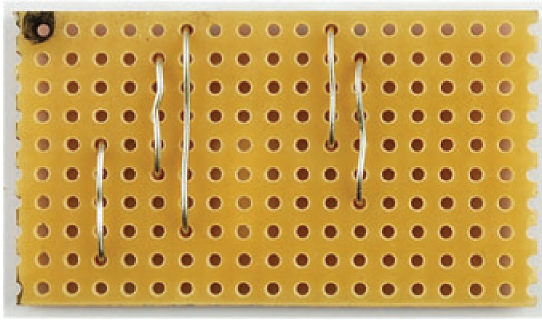


FIGURE 4-27 The stripboard with all its links

Step 5. Solder the Remaining Components

Next, solder the LED, capacitor (which can be laid on its side as shown in Figure 4-29), and finally the LEDs and connectors to the battery clip.

That's it. Now it's time for the moment of truth. Before you plug it in, do a very careful inspection for any shorts on the underside of the board.

If everything seems in order, connect the battery clip to the battery.

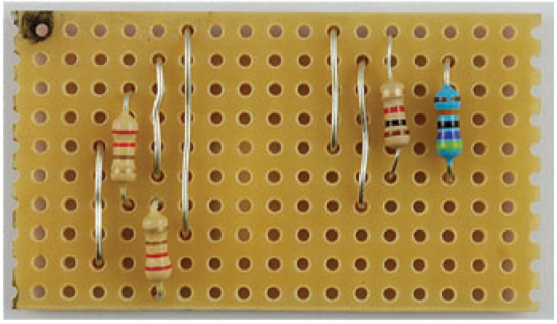

FIGURE 4-28 The stripboard with resistors in place

Troubleshooting

If it does not work, immediately unplug it and go back though and check everything, especially that the LEDs, IC, and capacitor are the correct way around. Also check that the batteries are okay.

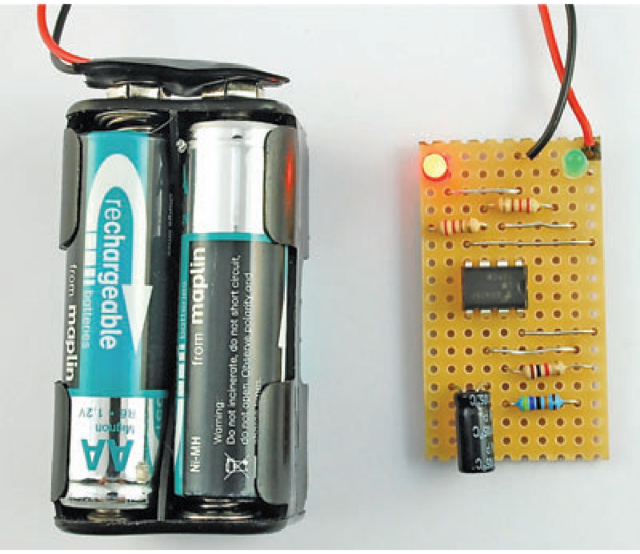

FIGURE 4-29 The LED flasher on the stripboard

How to Use a Laser Diode Module

Lasers are best bought as laser modules. The difference between a laser module and a laser diode is that the module includes a laser diode as well as a lens to focus the beam of laser light and a drive circuit to control the current to the laser diode.

If you buy a laser diode, you will have to do all this yourself.

A laser diode module, such as the 1-mW module shown in Figure 4-30, comes with a datasheet that says it needs to be supplied with 3V. So, all you need to do is find it a 3V battery and connect it up.

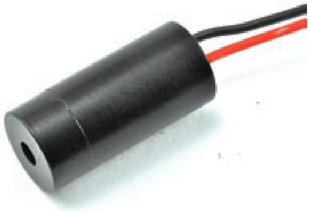

FIGURE 4-30 A laser diode module

Hacking a Slot Car Racer

Slot cars are a lot of fun, but could be improved by adding headlights and working brake lights to the car (Figure 4-31).

LEDs are just the right size to be fitted front and back into a slot car.

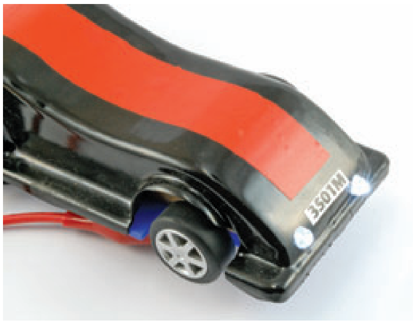

FIGURE 4-31 A modified slot car racer

You Will Need

You will need the following items to add lights to your slot car.

Quantity	Name	Item	Appendix Code
1		Slot car racer for modification	
1	D1	1N4001	S5, K1
2	D2, D3	High-brightness white LED 5rmm	S2
2	D4, D5	Red LED 5mm	S11
4	R1–4	1kΩ resistor	K2
1	C1	1000µF 16V-capacitor	C1
		Red, yellow, and black hookup wire	T7, T8, T9
1		* Two-way header plug and socket	

* I used a scavenged two-way header socket and plug to make it easier to work on the two halves of the car. This is not essential.

The slot car used here was part of a build-your-own slot car that has plenty of room inside for the electronics. Plan ahead and make sure you can fit everything in.

Storing Charge in a Capacitor

To make the brake lights stay on for a few moments after the car has stopped, you will need a capacitor to store charge.

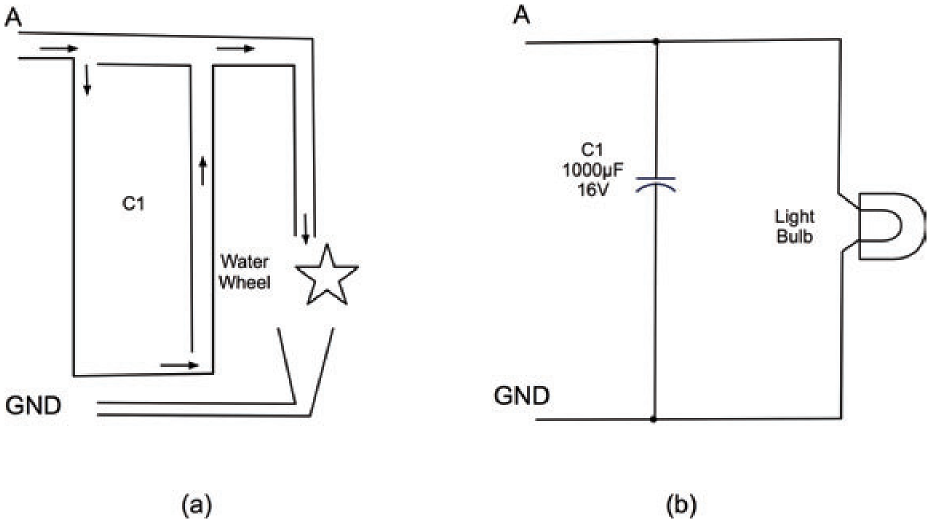
If you think back to the idea of electricity as water flowing in a river, then a capacitor is a bit like a storage tank. Figure 4-32 shows how a capacitor can be used to store charge.

Figure 4-32a shows a tank (c1) being filled with water through A. Throughout this, water will also flow along the top and drive a water wheel, turning electrical energy into motion, a bit like how a light bulb or LED turns electrical energy into light. The water falls out of the bottom, returning to ground. Imagine a pump (like a battery) pulling the water back up for another circuit. If the water stops flowing into C1 through A, then C1 will still be full of water that will keep the water wheel turning until the water level in C1 drops below that of the outlet of the water well.

Figure 4-32b shows the electronic equivalent of this circuit. While the voltage at A is higher than GND, C1 will fill with charge and the light will be lit.

When the voltage at A is disconnected, the capacitor will discharge through the light bulb, lighting it. As the level of voltage drops in the capacitor, the bulb will gradually dim until it goes out as it reaches GND.

Figure 4-32 A capacitor as a tank



On the face of it, you can think of capacitors as being a bit like batteries. Both store charge. However, there are some very important differences.

- Capacitors only store a tiny fraction of the charge that a battery of the same size can store.
- Batteries use a chemical reaction to store electrical energy. This means their voltage remains relatively constant until they are spent, at which time it falls off rapidly. Capacitors, however, drop evenly in voltage as they discharge, just like the level of water decreasing in a tank.

Design

Figure 4-33 shows the schematic diagram for this modification.

The headlights (D2 and D3) are powered all the time from the slot car's connection to the track, so whenever the motor is running the LEDs will light.

The brake lights are more interesting. These will automatically come on when the car stops, and then go off after a few seconds. To do this, we make use of a capacitor C1.

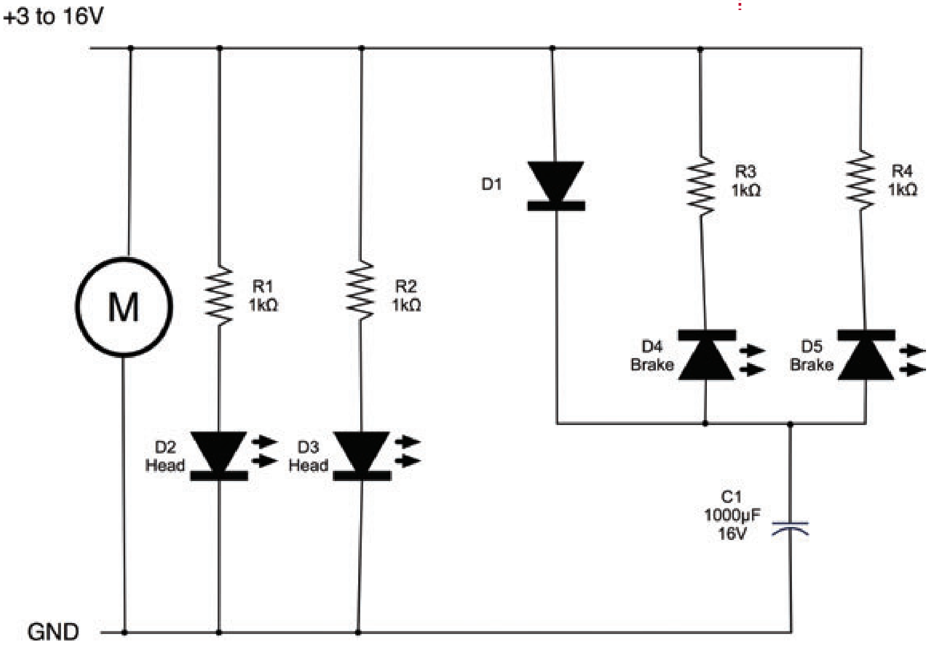


FIGURE 4-33 A schematic diagram for the slot car modification

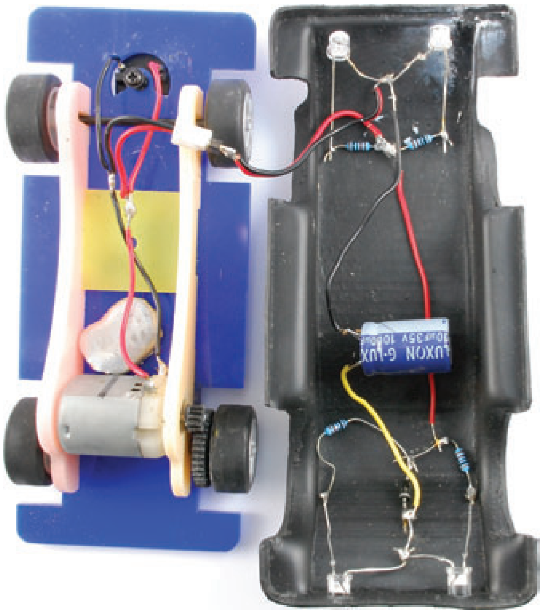

FIGURE 4-34 The components inside the car

When the car is powered, C1 will be charged through D1. At this point, the brake lights D4 and D5 will not be lit because they will be reverse-biased—that is, the voltage going in from the car tracks will be higher than the voltage at the top of the capacitor.

When you release the trigger on the controller, there will be no voltage coming in. Now the voltage at the top of the capacitor will be higher than the voltage coming in, so the capacitor will discharge through D4 and D5, making them light.

Construction

Figure 4-34 shows how the components are laid out in the two halves of the car.

How you lay these out in your vehicle may vary depending on how much space you have.

Holes were drilled in the case to take the 5mm LEDs. The LEDs are a snug fit in the holes and stay in place without any glue.

Figure 4-35 shows a wiring diagram for the arrangement that makes it easier to see what is going on.

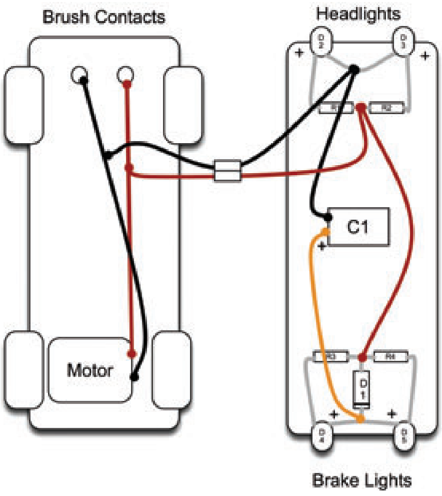

FIGURE 4-35 The wiring diagram for the modified car

Use your multimeter of the 20V range to identify which is the positive power connector on the contacts at the front of the car. This contact is connected to the red lead.

The longer leads of the LEDs are the positive connections, and the capacitor's negative lead should be marked with a "-".

The optional connector makes it easier to work on the two halves of the car separately.

Testing

Testing really just involves trying out the car on the track. If the headlight LEDs are not on as soon as you squeeze the trigger on the controller, check the wiring, paying special attention to the polarity of the LEDs.

Summary

We have learned how to use LEDs in this chapter, as well as picked up some good building skills so we can make our creations a bit more permanent using stripboard.

In the next chapter, we will examine sources of power, including batteries, power supplies, and solar panels. We will also look at how to select the right kind of battery, repurpose old rechargeable batteries, and use them in our projects.

5

Batteries and Power

Everything that you make or adapt is going to need to get its power from somewhere. This might be from a household electricity adapter, solar panels, rechargeable batteries of various sorts, or just standard AA batteries.

In this chapter, you will find out all about batteries and power, starting with batteries.

Note I use the word "battery" to describe both batteries and cells. Strictly speaking, a battery is a collection of cells wired one after the other to give the desired voltage.

Selecting the Right Battery

There are many types of battery on the market. So, to simplify things, in this chapter we will just look at the most common types of battery, those that are readily available and that will be used in most of the devices in this book.

Battery Capacity

Whether single-use or rechargeable, batteries have a capacity—that is, they hold a certain amount of electricity. Manufacturers of single-use batteries often don't specify this capacity in the batteries you buy from a supermarket. They just label them heavy duty / light duty, and so on. This is a little like having to buy milk and being given the choice of "big bottle" or "small bottle" without being able to see how big the bottle is or be told how many pints or liters it contains. One can speculate as to the reasons for this. One reason might be that battery producers think the public isn't intelligent enough to understand a stated battery capacity. Another might be that the longer a battery is on the shelf, the more its capacity shrinks. Still another is that the capacity actually varies a lot with the current drawn from the battery.

Anyway, if a battery manufacturer is kind enough to tell you what you are buying, the capacity figure will be stated in Ah or mAh. So a battery that claims to have a capacity of 3000mAh (typical of a single-use alkaline AA cell) can supply 3000mA for one hour. Or, alternatively, 3A for an hour. But it doesn't have to draw 3A. If your project only uses 30mA, you can expect the battery to last 100 hours (3000/30). In truth, the relationship is not quite that simple, because as you draw more current, the capacity decreases. Nevertheless, this will do as a rule of thumb.

Maximum Discharge Rate

You cannot take a tiny battery like a CR2032 with a capacity of 200mAh and expect to power a big electric motor at 20A for 1/100 of an hour (six minutes). There are two reasons for this. First, all batteries actually have an internal resistance. So, it is as if there is a resistor connected to one of the terminals. This varies depending on the current being drawn from the battery, but may be as high as a few tens of ohms. This will naturally limit the current.

Second, when a battery is discharged too quickly, by too high a current, it gets hot—sometimes very hot, sometimes "on fire" hot. This will damage the battery.

Batteries therefore also have a safe discharge rate, which is the maximum current you can safely draw from it.

Single-Use Batteries

Although somewhat wasteful, sometimes it makes sense to use single-use batteries that cannot be recharged. You should consider single-use batteries if:

- The project uses very little power, so they will last a long time anyway.
- The project will never be close to someplace where it can be charged up.

Table 5-1 shows some common single-use batteries. These figures are typical values and will vary a lot between actual devices.

Especially when it comes to the maximum discharge rate, you may get away with a lot more, or the battery may fail or get very hot with considerably less. It will also depend on how well ventilated a box they are in, as heating under high currents is a big problem.

So in the spirit of hacking electronics, spend less time planning and more time trying. See how hot it gets and how long it lasts. After all, we are having fun here, not designing a product.

Type	Typical Capacity	Voltage	Max. Discharge Current	Features	Common Uses
Lithium button cell (e.g., CR2032)	200mAh	3V	4mA with pulses up to 12mA	High temperature range (–30 to 80ºC); small	Low-power devices; RF remote controls; LED key ring lights, etc.
Alkaline PP3 battery	500mAh	9V	800mA	Low cost; readily available	Small portable electronic devices; smoke alarms; guitar pedals
Lithium PP3	1200mAh	9V	400mA pulses up to 800mA	Expensive; light; high-capacity	Radio receivers
AAA cell	800mAh	1.5V	1.5A continuous	Low-cost; readily available	Small motorized toys; remote controls
AA cell	3000mAh	1.5V	2A continuous	Low cost; readily available	Motorized toys
C cell	6000mAh	1.5V	Probably get away with 4A	High-capacity	Motorized toys; high-powered flashlights
D cell	15,000mAh	1.5V	Probably get away with 6A	High-capacity	Motorized toys; high-powered flashlights

TABLE 5-1 Single-Use Battery Types

Note Some of the photographs in the table are of branded batteries. The figures shown are for batteries of that type, not specifically the batteries listed.

Roll Your Own Battery

A single-cell battery with a voltage of just 1.5V is probably not going to be of any use. You will normally need to put a number of these cells in series (end to end) to produce a battery of the desired voltage.

When you do this, you do not increase the capacity. If each cell was 2000mAh, then if you put four 1.5V batteries in series, the capacity would still be 2000mAh, but at 6V rather than 1.5V.

Battery holders such as the one shown in Figure 5-1 are a great way of doing this. Look closely at how the battery holder is constructed and you'll notice how the positive of one battery is connected to the negative of the next, and so on.

This holder is designed to take six AA batteries so as to produce an overall voltage of 9V. Battery holders like this are available to take two, four, six, eight, or ten cells, both in AA and AAA.

Another advantage of using a battery holder is that you can use rechargeable batteries instead of single-use batteries. However, rechargeable cells normally have a lower voltage, so you have to take this into account when calculating the overall voltage of your battery pack.

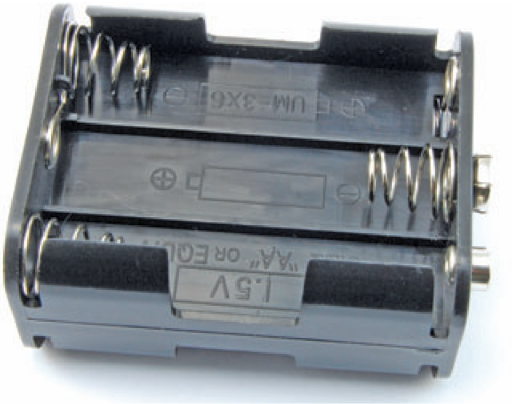

FIGURE 5-1 A battery holder

Selecting a Battery

Table 5-2 should help you decide on a suitable battery for your project. There is not always a best answer to the question "Which battery should I use?" and this table is definitely in the territory of rules of thumb.

You should also do the math and include how frequently the battery will need replacing.

	Voltage			
Power	**3V**	**6V**	**9V**	**12V**
Less than 4mA (short bursts) or 12mA continuous	Lithium button cell (e.g., CR2032)	2 × Lithium button cell (e.g., CR2032)	PP3	Unlikely
Less than 3A (short bursts) or 1.5A continuous	2 × AAA battery pack	4 × AAA battery pack	6 × AAA battery pack	8 × AAA battery pack
Less than 5A (short bursts) or 2A continuous	2 × AAA battery pack	4 × AAA battery pack	6 × AAA battery pack	8 × AAA battery pack
Even more	2 × C or D battery pack	4 × C or D battery pack	6 × C or D battery pack	8 × C or D battery pack

TABLE 5-2 Selecting a Single-Use Battery

Rechargeable Batteries

Rechargeable batteries can provide both cost and green benefits over single-use batteries. They are available in different types and in different capacities. Some, such as rechargeable AA or

AAA batteries, are designed as replacements for single-use batteries, and you remove them to charge in a separate charger. Other batteries are intended to be built into your project so all you have to do is plug a power adapter into your project to charge the batteries without removing them. The advent of cheap, high-capacity, low-weight lithium polymer (LiPo) batteries has made this a common approach for many items of consumer electronics.

Table 5-3 shows some commonly used types of rechargeable batteries.

Although there are many more types than this, these are the most commonly used batteries. Each type of battery has its own needs when it comes to charging, and we will look at each in later sections.

Type		Typical Capacity	Voltage	Features	Common Uses
NiMH button cell pack		80mAh	2.4 or 3.6V	Small	Battery backup
NiMH AAA cell		750mAh	1.25V	Low cost	Replacement for single-use AAA cell
NiMH AA cell		2000mAh	1.25V	Low cost	Replacement for single-use AA cell
NiMH C cell		4000mAh	1.25V	High capacity	Replacement for single-use C cell
Small LiPo cell		50mAh	3.7V	Low cost; high capacity for weight and size	Micro-helicopters
LC18650 LiPo cell		2200mAh	3.7V	Low cost; high capacity for weight and size; slightly bigger than AA	High-power flashlights; Tesla Roadster (yes, really—about 6800 of them)
LiPo pack		900mAh	7.4V	Low cost; high capacity for weight and size	Cell phones, iPods, etc.
Sealed lead–acid battery		1200mAh	6/12V	Easy to charge and use; heavy	Intruder alarms; small electric vehicles / wheelchairs

TABLE 5-3 Rechargeable Batteries

	NiMH	LiPo	Lead–Acid
Cost per mAh	Medium	Medium	Low
Weight per mAh	Medium	Low	High
Self-discharge	High (flat in 2–3 months)	Low (6% per month)	Low (4% per month)
Handling of full charge/ discharge cycles	Good	Good	Good
Handling of shallow discharge/charge	Medium (regular full discharge prolongs battery life)	Medium (not well-suited to trickle charging)	Good

TABLE 5-4 Characteristics of Different Battery Technologies

Table 5-4 summarizes the features of NiMH, LiPo, and lead–acid battery technologies.

If you want your project to charge a battery in place, then a LiPo or sealed lead–acid battery is probably the best choice. However, if you want the option to remove the battery and/or use single-use batteries, then a AA battery pack is a good compromise between capacity and size.

For ultra-high-power projects, lead–acid batteries, despite being an ancient technology, still perform pretty well, just as long as you don't have to carry them around! They are also easy to charge and are the most robust of the technologies, offering the least chance of fire or explosion.

Charging Batteries (in General)

Certain principals apply no matter what kind of battery you are charging. So read this section before reading those that follow it concerning specific battery types.

C

The letter C is used to denote the capacity of a battery in Ah or mAh. So, when people talk about charging a battery, they often talk about charging at 0.1C or C/10. Charging a battery at 0.1C means charging it at 1/10 of its capacity per hour. For example, if a battery has a capacity of 2000mAh, then charging it at 0.1C means charging it with a constant current of 200mA.

Over-Charging

Most batteries do not respond well to being over-charged. If you keep supplying them with a high charging current, you will damage them. They often also get hot. In the case of LiPo batteries, this can be "hot" in a fiery sort of way.

For this reason, chargers often charge at a low rate (called trickle charging), so that the low current will not damage the battery. Clearly this makes charging slow. Or, they will use a timer or other circuitry to detect when a battery is full and either stop charging altogether, or switch to trickle charging, which keeps the battery topped up until you are ready to use it.

With some kinds of battery, notably LiPos and the lead–acid variety, if you charge the battery with a constant voltage, then as the battery becomes charged, its voltage rises to match the charging voltage and the current naturally levels off.

Many LiPo batteries now come with a little built-in chip that prevents over-charging automatically. Always look for batteries with such protection.

Over-Discharging

You are probably starting to get the impression that rechargeable batteries are fussy. If so, you're right. Most types of battery are equally unhappy if you over-discharge them and let them go completely flat.

Battery Life

Anyone with a laptop more than a few years old will notice that the capacity of the battery gradually decreases until the laptop only works when plugged in, since the battery has become completely useless. Rechargeable batteries (whatever the technology) can only be recharged a few hundred (perhaps 500) times before needing to be replaced.

Many manufacturers of consumer electronics now build the battery into the device in such a way that it is not "user serviceable," with the rationale that the life of the battery is probably longer than the attention span of the consumer.

How to Charge a NiMH Battery

If you are going to remove your batteries to charge them, this section is pretty trivial. You take them out and put them in a commercial NiMH battery charger that will charge them until they are full and then stop. You can then put them back into your project and you are done.

If, on the other hand, you want to leave the batteries in place while you charge them, then you need to understand a little more about the best way to charge your NiMH batteries.

Simple Charging

The easiest way to charge a NiMH battery pack is to trickle charge it, limiting the current with a resistor. Figure 5-2 shows the schematic for charging a battery pack of four NiMH batteries using a 12V DC adaptor like the one we used back in Chapter 1 to make our fume extractor.

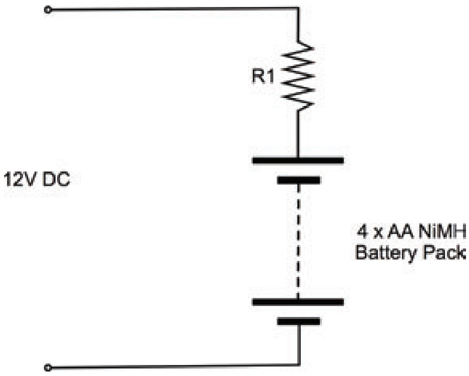

Figure 5-2 Schematic for trickle charging a NiMH battery pack

To calculate the value of R1, we first have to decide what current we want to charge our battery with. Generally, a NiMH battery can be safely trickle charged with less than 0.1C indefinitely. If the AA batteries we have each hold a C of 2000mAh, then we can charge them at up to 200mA. To be on the safe side, and if we planned to allow the batteries to "trickle" charge most of the time—for, say, a battery backup project—I would probably use a lower current of 0.05C or more conveniently C/20, which is 100mA.

Typically, the charge time for NiMH batteries is about 3C times the charging current, so at 100mA, we could expect our batteries to take 3 × 2000mAh / 100mA = 60 hours.

Back to calculating R1. When the batteries are discharged, each will be at a voltage of about 1.0V, so the voltage across the resistor will be 12V – 4V = 8V.

Using Ohm's law, R = V / I = 8V / 0.1A = 80Ω.

Let's be conservative and choose the convenient resistor value of 100Ω. Feeding this back in, the actual current will be I = V / R = 8V / 100Ω = 80mA.

When the batteries are fully charged, their voltage will rise to about 1.3V so the current will reduce to: I = V / R = (12V – 1.3V × 4) / 100Ω = 68mA.

That all sounds just fine, our 100Ω will be great. Now we just need to find out what maximum power rating we need for R1.

$$P = I\,V = 0.08A \times 8 = 0.64W = 640\text{ mW}$$

So, we should probably use a 1-W resistor.

Fast Charging

If you want to charge the batteries faster than that, then it is probably best to use a commercial charger, which will monitor the batteries and turn itself off or reduce the charge to a trickle when the batteries are full.

How to Charge a Sealed Lead–Acid Battery

These batteries are the least delicate of the battery types and could easily be trickle charged using the same approach as for NiMH batteries.

Charging with a Variable Power Supply

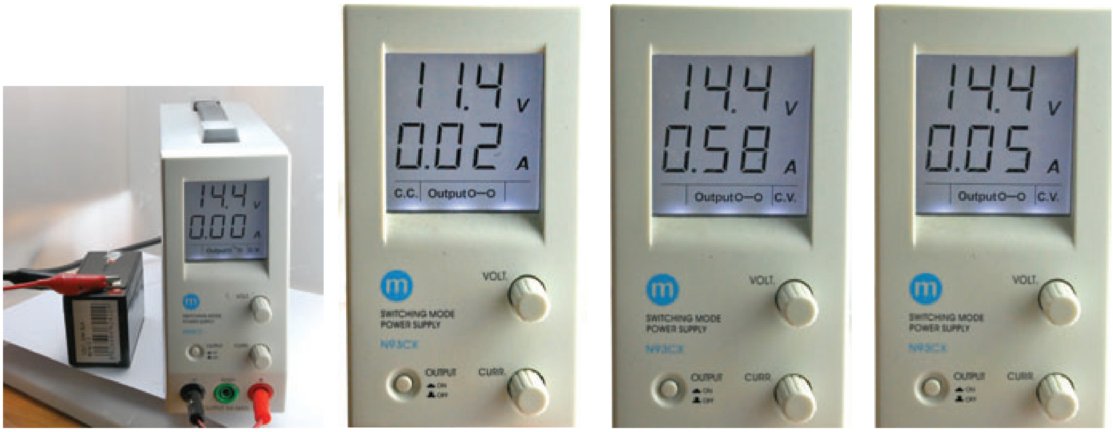
However, if you want to charge them faster, then it is best to charge them with a fixed voltage, with some current limiting (a resistor again). For a 12V battery (halve this for a 6V battery) until a discharged battery gets to around 14.4V, you can charge it with almost as much current as your power supply can take. It's only when it gets to this voltage that you need to slow down the charging to a trickle to prevent the battery from getting hot.

The reason we need to limit the current when the battery first starts to charge is that even if the battery doesn't get hot, the wires to it might get hot and whatever is supplying the voltage will only be able to supply a certain amount of current.

Figure 5-3 shows an adjustable power supply. Once you get into electronics, this is one of the first pieces of test equipment you should buy. You can use it in place of batteries while you are working on a project, and also use it to charge up pretty much any type of rechargeable battery.

A variable power supply lets you set both an output voltage and a maximum current. So the power supply will try and supply the specified voltage until the current limit is reached, at which point, the voltage will drop until the current falls back below the set current.

Figure 5-3a shows the power supply set to 14.4V and we have attached the power leads to an empty 12V 1.3Ah sealed lead–acid battery. We will start by adjusting the current setting of the power



(a) (b) (c) (d)

Figure 5-3 Using a variable power supply to charge a lead–acid battery

supply to minimum, so as to prevent any nasty surprises. The voltage immediately drops to 11.4V (Figure 5-3b), so we can gradually increase the maximum current. In actual fact, even with no current limiting (turning the current knob to maximum), the current only rose to 580mA and the voltage increases to 14.4V (Figure 5-3c). After about two hours, the current has dropped to just 200mA, indicating that our battery is getting full. Finally, after four hours, the current is just 50mA and the battery is now fully charged (Figure 5-3d).

How to Charge a LiPo Battery

The technique we have just used on a lead–acid battery using a variable power supply will work just as well on a LiPo battery if we adjust the voltage and current accordingly.

For a LiPo cell, the voltage should be set to 4.2V and the current limited (usually to 0.5A) for a smallish cell, but currents up to C are sometimes used in radio-controlled vehicles.

However, unlike lead–acid and NiMH batteries, you cannot put a number of cells in series and charge the whole lot as one battery. Instead, you have to charge them separately, or use a "balanced charger" that monitors the voltage at each cell separately and controls the power to each.

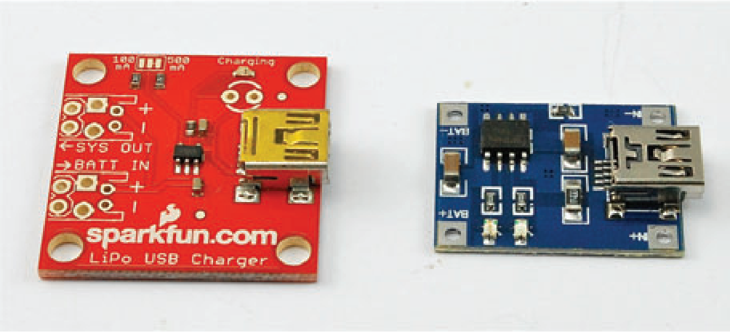


FIGURE 5-4 SparkFun and generic LiPo chargers

The safest and most reliable way to charge a LiPo is to use one of the chips that exist just for that purpose. These chips are cheap, but generally only available as surface-mounted components. However, there are plenty of ready-made modules available, many of which use the MCP73831 IC. Figure 5-4 shows two of these—one from SparkFun (see the Appendix, M16) and one for just a few dollars from eBay.

Both are used in the same manner. They will charge a single LiPo cell (3.7V) from a USB input of 5V. The SparkFun board has space on the PCB for two other connectors, one to which the battery is connected and the other for a second connection to the battery—the intention is that you connect the electronics that will use the battery to the second socket. The sockets can be either JST connectors as are often found on the end of the leads of a LiPo batter, or just screw terminals. The SparkFun module allows you to select the charging current, using a connection pad.

The generic module on the right has a fixed charge rate of 500mA and just a single pair of connections for the battery.

It is not a good idea to trickle charge a LiPo. If you want to keep them topped up, for say a battery backup solution, then leave them attached to the charger.

Hacking a Cell Phone Battery

Most of us have a cell phone or two languishing in a drawer somewhere, and one of the useful components that can usually be scavenged (assuming it's not the reason the phone is in the drawer) is the battery. The power supply is another useful item.

Figure 5-5a shows a fairly typical vintage cell phone battery. The battery is 3.7V (a single cell) and is 1600mAh (pretty good).

FIGURE 5-5 Hacking a cell phone battery

Cell phone batteries normally have more than just the usual two connections for positive and negative. So the first task must be to identify the connections on the battery.

To identify the positive and negative connections to the cell, just put your multimeter into the 20V DC range and test each combination of pairs until you get the meter to read something over 3.5V, depending on how well charged the battery is (Figure 5-5b).

The batteries often have gold-plated contacts that make them very easy to solder leads to. Once they have leads attached, you can use a charger like the one described in the previous section. Figure 5-5c shows the SparkFun charger module being used for just that purpose.

Caution When using a LiPo battery, remember that if you discharge them too far (below about 3V per cell), you can permanently damage them. Most new LiPo batteries will include an automatic cut-off circuit, built into the battery package, to prevent over-discharging, but this may not be the case for a scavenged battery.

Controlling the Voltage from a Battery

The thing with batteries is that even though they may say 1.5V, 3.7V, or 9V on the package, their voltage will drop as they discharge—often by quite a high percentage.

For example, a 1.5V alkaline AA battery when brand new will be about 1.5V and will quickly fall to about 1.3V under load but still deliver useful amounts of power down to about 1V. This means that in a pack of four AA batteries, the voltage could be anything between 6V and 4V. Most types of battery, whether single-use or rechargeable, exhibit a similar voltage drop.

This may not matter much; it just depends on what the battery is powering. If it is powering a motor or an LED, then the motor will just go a bit more slowly, or the LED will be a little dimmer as the battery discharges. However, some ICs have a very narrow voltage tolerance. There are ICs designed to work at 3.3V that specify a maximum working voltage of 3.6V. Similarly, if the voltage drops too low, the device will also stop working.

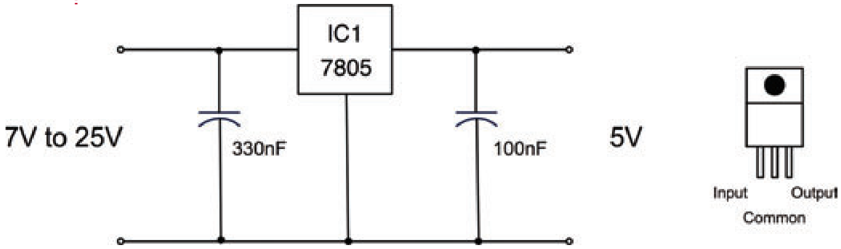
In fact, many digital chips such as microcontrollers are designed to work at a standard voltage of 3.3V or 5V.

To ensure a steady voltage, we need to use something called a voltage regulator. Fortunately for us, voltage regulators come as convenient three-pin, low-cost chips that are very easy to use. In fact, the packages just look like transistors, and the bigger the package, the more current they can control.

Figure 5-6 shows how you would use the most common of voltage regulators, called the 7805.

Using just a voltage regulator IC and two capacitors, any input voltage between 7V and 25V can be regulated to a constant 5V. The capacitors provide little reservoirs of charge that keep the regulator IC operating in a stable manner.

Figure 5-6 A voltage regulator schematic



In the following experiment with a 7805, we will omit the capacitors, as the supply voltage is a steady 9V battery and the load on the output is just a resistor (Figure 5-7).

The capacitors become much more necessary when the load varies (in other words, in the amount of current that it draws), something that is true of most circuits.

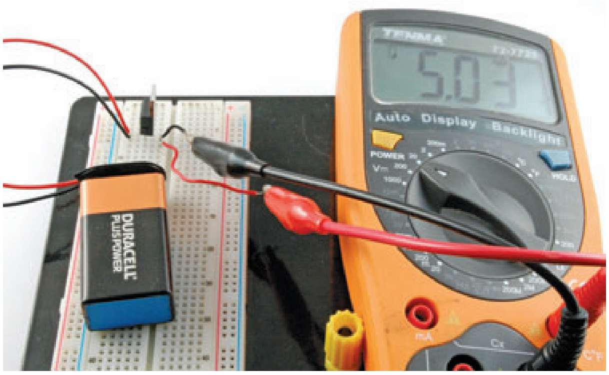


Figure 5-7 Experimenting with the 7805

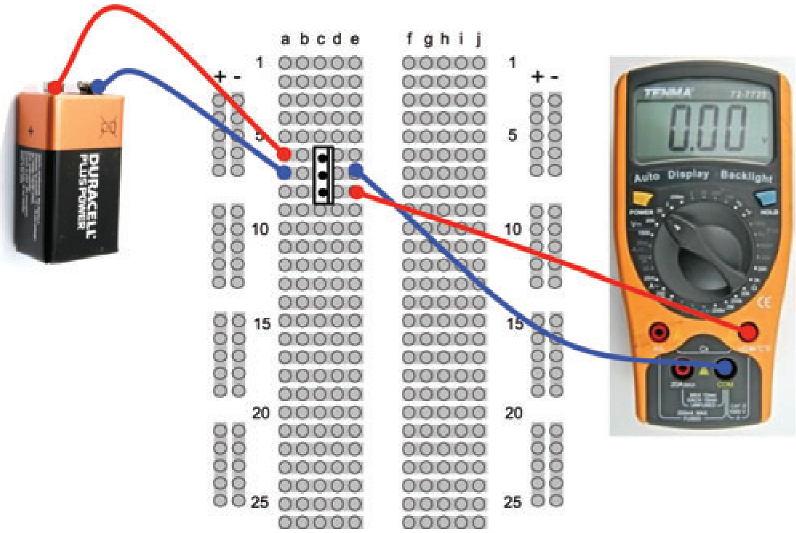
You Will Need

Quantity	Names	Item	Appendix Code
1		Solderless breadboard	T5
1	IC1	7805 voltage regulator	K1, S4
1		Battery clip	H2
1		9V PP3 battery	

Wire up the breadboard as shown in Figure 5-8.

Figure 5-8 The 7805 breadboard layout



Breadboard

With the battery connected, the multimeter should display a voltage of close to 5V.

Although 5V is a very common voltage, there are voltage regulators for most common voltages, as well as the LM317 voltage regulator that we discussed in Chapter 4, that as well as providing constant current, can also be configured as a voltage regulator.

Table 5-5 lists some common voltage regulators that provide different output voltages and different current handling capabilities.

Output Voltage	100mA	1–2A
3.3V	78L33	LF33CV
5V	78L05	7805 (App A S4) (7–25V in)
9V	78L09	7809
12V	78L12	7812

TABLE 5-5 Voltage Regulators

Boosting Voltage

The voltage regulator ICs in the section titled “Controlling the Voltage from a Battery” only work if the input voltage is greater than the output voltage. In fact, it normally has to be a couple of volts higher, but some more expensive voltage regulators called LDO (low drop out) regulators are available that only require about half a volt more on the input than the output.

Sometimes, however—and cellular phones are a good example of this—it is very convenient to use a single-cell LiPo battery of 3.7V when we require a higher voltage (often 5V) for the circuit.

In these situations, you can employ a very useful circuit called a buck-boost converter. These use an IC and a small inductor (coil of wire) and by applying pulses to the inductor, produce a higher voltage. Actually, it’s more complex than that, but you get the idea.

Buck-boost converters are readily available as modules on well-known auction sites. You can find 1A adjustable modules that will provide an adjustable output of 5V to 25V from 3.7V for a few dollars. Try searching for “Boost Step-Up 3.7V.” The main module suppliers also provide such boards for around USD 5.

SparkFun sells an interesting module (see the Appendix, M17) that combines a LiPo battery charger with a buck-boost, so you can both charge your LiPo from an external USB 5V input and use the 3.7V LiPo cell to provide an output of 5V using the buck-boost (Figure 5-9).

This actually takes all the difficulties away from using a LiPo in a situation where you want to charge the LiPo battery in situ. Your 5V microcontroller circuit or whatever you are using is just attached to the VCC and GND connections, the battery is clipped into the socket, and to charge the device, you just plug in a USB cable.

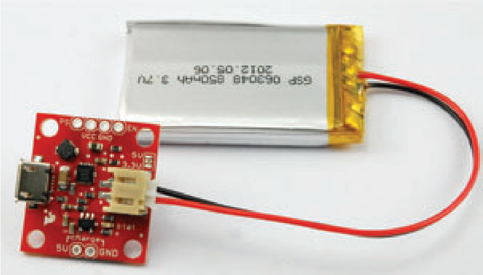


Figure 5-9 Combined LiPo charger and booster

Calculating How Long a Battery Will Last

We have already touched on the capacity of a battery—that is, the number of mAh it can supply. However, other factors come into play that we should think about when deciding if the batteries we are considering for a project are going to last long enough.

It's really just a matter of common sense, but nevertheless it's easy to make false assumptions about what you need.

As an example, I recently built an automated door for my chicken house. It opens at dawn and closes when it gets dark. It uses an electric motor, and electric motors use a lot of current, so I needed to decide what kind of batteries to use. My first thought was to use big D cells or a lead–acid battery. But when it came to do the math, I found this wasn't really necessary.

Although the motor uses 1A each time it is in operation, it is only in operation twice a day, and each time only for about three seconds. I measured the control circuit as using 1mA all the time. So, let's work out how many mAh the control circuit and motors each use in a day, and then see how many days various types of battery will last.

Let's start with the motors:

1A × 3 seconds × 2 = 6As = 6/3600Ah = 0.0016 Ah = 1.6mAh per day

On the other hand, the controller, which I had assumed was the low power part of the project would consume:

1mA × 24 hours = 24mAh per day

This means we can pretty much ignore the power consumed by the motor since it is less than a tenth of the juice required by the controller. Let's say the total requirement is 25mAh/day.

AA batteries are typically 3000mAh, so if we powered the project from AA batteries, we could expect them to last 3000mAh / 25mAh per day = 120 days.

So we do not really need to look much further, AAs will be fine. In the end, I used solar power for this project, which we will visit again in the section titled “How to Use Solar Cells” later in this chapter.

How to Design for Battery Backup

Replacing batteries is a nuisance, and expensive, so it is often cheaper and more convenient to power things from a wall-wart power supply. However, this brings its own disadvantages:

- The device is now tethered to a wire.
- If the household electricity fails, the device will stop working.

The best of both worlds can be achieved by arranging for automatic battery backup of a device that is powered by your household electricity. So, both batteries and a power supply are used, but the batteries are only used if the power supply is not available.

Diodes

What we do not want to happen is for both the batteries and the voltage from the power supply to conflict with each other when both are available. For instance, if the power supply is at a higher voltage than the batteries, it would charge them. But without anything to limit the current, this could be disastrous, even if the batteries were of the rechargeable sort.

FIGURE 5-10 Battery backup schematic

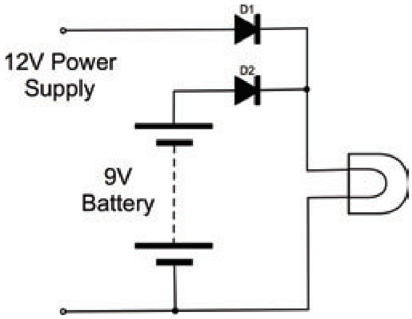

Figure 5-10 shows the basic schematic for this. The power supply always needs to be a higher voltage than the battery, so in this case it is 12V and the battery 9V. The schematic also assumes that the battery backup is being used to drive a light bulb.

Recall that diodes act rather like one-way valves. They only allow current to flow in the direction of the arrow. So, let’s look at the three possible cases of how power could be supplied here. This is simply the power supply: just batteries and both the battery and power supply (Figure 5-11).

(c) Both Power Supply and Battery

FIGURE 5-11 Diodes for battery backup

Just the Battery

If only the battery has a voltage greater than zero (in other words, the power supply is not plugged in), then the situation is as shown in Figure 5-11a. The 9V from the battery will be at the anode of D2, and the cathode of D2 will be pulled toward ground by the load of the light bulb. This will cause D2 to be forward-biased and conduct the current through the light bulb. A forward-biased diode will have an almost constant voltage of 0.5V across it, which is why we can say that the voltage after the diode is 8.5V.

On the other hand, D1 will have a higher voltage (8.5V) on its cathode (right-hand side in the diagram) than its anode (0V), so no current will flow through D1.

Just the Power Supply

If just the power supply is connected (Figure 5-11b), then the role of the diodes is reversed and now the current flows through D1 to the light bulb.

Both the Power Supply and the Battery

Figure 5-11c shows the situation where both the power supply and the battery are connected. The 12V of the power supply will ensure that the cathode of D2 is at 11.5V. Since the anode of D2 is at 9V from the battery, the diode will remain reverse-biased and no current will flow through it.

Trickle Charging

As we already have a battery and a power supply, we have most of the ingredients we need to charge the battery. We could for example use six AA rechargeable batteries in a battery box and arrange to charge them at C/20 (assuming C = 2000mAh) or 100mA from the power supply.

That way, the batteries would always be charged, and provide light whenever the power failed. Figure 5-12 shows the schematic for this.

You may not have been expecting the extra diode D3. This is really just to account for the fact that we do not know exactly how the power supply is designed, so we do not know what would happen if the battery was connected to its output (via R1) when it was turned off. This may discharge the battery or damage the power supply. The diode D3 just protects it and makes sure no current can flow back into it.

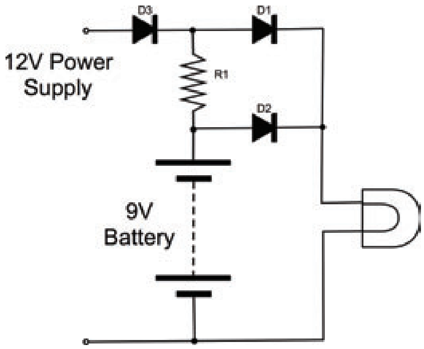

FIGURE 5-12 Battery backup and charging

We want a charging current of 100mA to flow through R1, and we know that when both the power supply and battery are connected, there will be a voltage across R1 of 12V – 0.5V – 9V or 2.5V. So, using Ohm's law, the value of the resistor should be:

$$R = V / I = 2.5 / 0.1A = 25\Omega$$

The nearest standard value to this is probably 27Ω.

Its power requirement: $P = V^2 / R = 2.5^2 / 27 = 0.23W$

This means a standard half- or quarter-watt resistor will be fine.

How to Use Solar Cells

On the face of it, solar cells seem like the perfect power source. They convert light into electricity, and so in theory you need never change a battery or be plugged into a wall outlet again!

However, as always, the reality is not quite so simple. Solar cells, unless they are very large, produce fairly small amounts of electricity and so are most suited to low-power devices and projects that are outdoors away from household electricity.

If you are thinking of trying a solar project that will be installed indoors, unless it will be sited against a south-facing window, I really wouldn't try it. Solar cells do not require direct sunlight, but to produce any useful amounts of electricity, they really need a good unobstructed view of the sky.

Two solar projects I have developed are a solar-powered radio (the solar panel is as big as the radio and, yes, it needs to be next to the window), and a solar-operated chicken house door. If you are lucky enough to live somewhere sunny, then solar power is obviously a lot easier.

Figure 5-13 shows a typical solar panel. This one was scavenged from a security light installation. It is about six inches by four inches and has a swivel mount that allows it to be angled toward the sun. It is the panel I used for the chicken house door.

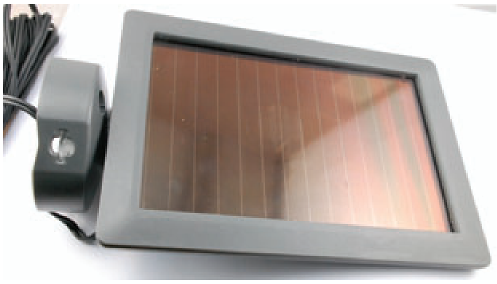

FIGURE 5-13 A solar panel

Projects that use a solar panel to provide power nearly always also use a rechargeable battery. So the panel charges the battery and the project draws its power from the battery.

Small solar cells generally only produce around half a volt, so they are usually combined into panels of many cells that increase the voltage to a level that is high enough to charge a battery.

The voltage you find on a solar panel normally refers to the voltage of battery that the solar panel is capable of charging. So, it is quite common to find 6V or 12V solar panels. When you measure the voltage from these in bright sunlight, the reading will be much higher, possibly 20V for a 12V panel. But, under the load of charging a battery, this drops rapidly.

Testing a Solar Panel

A solar panel will have a certain number of watts and a nominal voltage specified for it. These tend to be for ideal conditions, so when I get a solar panel that I want to use in a project, I like to test it to find what it is really capable of. Without knowing how much power it can provide in a real situation where it's installed, it is hard to make safe assumptions about battery capacities and how low you need to keep the current consumption.

When testing out a solar panel, you should use a resistor as a "dummy load," and then try out the solar panel in various locations and levels of brightness, measuring the voltage across the resistor. From this, you can calculate the current being provided by the panel.

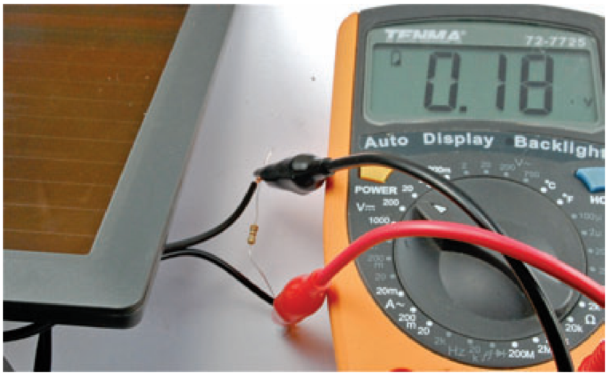

FIGURE 5-14 Testing a solar panel

Figure 5-14 shows such an arrangement for my "chicken house" solar panel. The meter is showing just 0.18V with a 100Ω load resistor inside the light box that I use for my photography. That equates to just 1.8 mA.

I find a spreadsheet a useful way of recording how the solar panel performs. Figure 5-15 shows an excerpt from the spreadsheet, complete with graph. You can then file this away until the next time you wish to use a solar panel in a project.

The spreadsheet can be downloaded from www.hackingelectronics.com, but there is really nothing complex about the math.

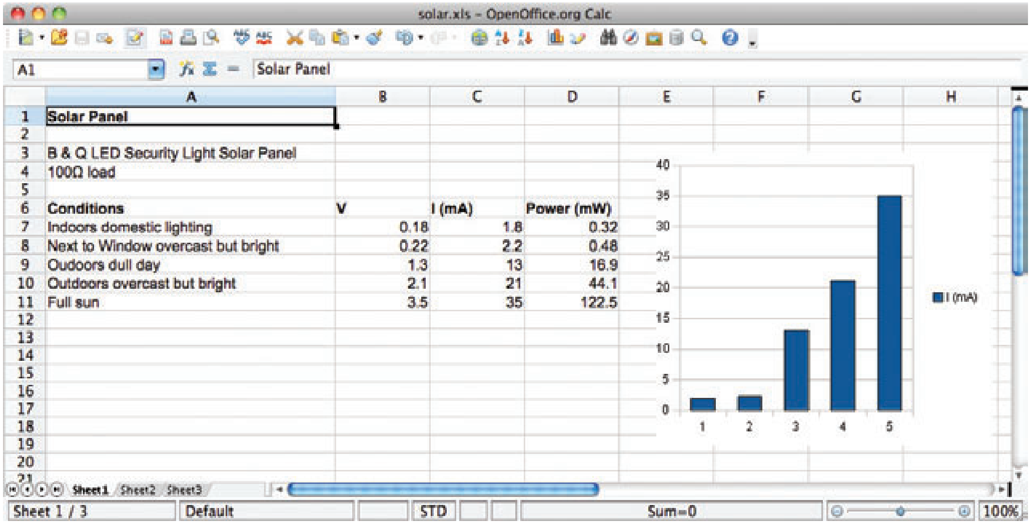
As you can see, the solar panel produces only 1 or 2mA indoors even under bright artificial lighting. The results outdoors with a clear view of the sky are better, but it really only produces quite high power in direct sunlight.

Trickle Charging with a Solar Panel

Since the solar panels produce a reasonable voltage, even in relatively low light conditions, they can easily be used to trickle charge a battery. However, you should always use a diode to protect the solar panel from the situation where the battery is at a higher voltage than the panel (say at night), since such a reverse flow will damage the solar panel.

A typical simple trickle charge schematic is shown in Figure 5-16.

FIGURE 5-15 Solar panel data



solar.xls - OpenOffice.org Calc

A1 Solar Panel

Solar Panel

B & Q LED Security Light Solar Panel

100Ω load

Conditions	V	I (mA)	Power (mW)
Indoors domestic lighting	0.18	1.8	0.32
Next to Window overcast but bright	0.22	2.2	0.48
Oudoors dull day	1.3	13	16.9
Outdoors overcast but bright	2.1	21	44.1
Full sun	3.5	35	122.5

Lead–acid batteries are still a very popular choice for trickle charging from solar. This is mainly because they are very forgiving of gentle over-charging and have a lower self-discharge rate than, say, NiMH batteries.

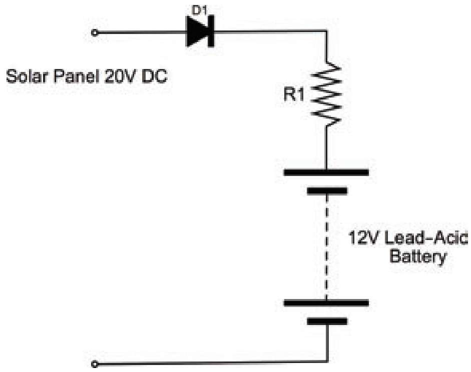


Figure 5-16 Schematic for solar trickle charging

Minimizing Power Consumption

When planning solar power for some small outdoor project, you need to make sure the solar panel charging the battery can keep up with demand.

If you live in southern California, the design for using solar panels is pretty easy. You can count on quite a lot of sun all year long. However, if you live a long way from the equator, say, in a maritime climate where it's often quite dull during the day, then you will have short winter days. You may get weeks of dull weather with short days. If your system is to work all year long, you either need to have a large battery that will last for a few weeks of dull weather, or use a larger solar panel.

The sums are pretty easy. There are mAh going into the battery from the solar panel, and mAh coming out for the device it is powering. The device might be running all the time, but the solar panel is only active half the time (daylight). So, you need to work out what you think the worst case for solar input might be for a week or two, and then design it accordingly.

It will probably be easier and cheaper to put your efforts into minimizing the current consumed by the system rather than increasing the size of the solar panel and battery.

Summary

In this chapter, we have learned about how to power our projects. In the next chapter, you will learn how to use the very popular Arduino microcontroller board.

6

Hacking Arduino

Microcontrollers are essentially low-powered computers on a chip. They have input/output pins to which you can attach electronics so the microcontroller can, well, control things. Utilizing a microcontroller used to be quite a complex process, largely because the microcontroller needed to be programmed. This was often done in assembler or complex C. But there was a lot to learn before you could do anything useful. Because of this, it discouraged their use in casual projects where you just wanted to hack something together.

Enter the Arduino (Figure 6-1). The Arduino is a simple-to-use, low-cost, readymade board that lets you use a microcontroller in your projects with a minimum of fuss.

The Arduino sells in vast quantities and has become the platform of choice for makers and hackers in need of microcontrollers.

The popularity of Arduino is due to many factors, including its:

- Low cost
- Open-source hardware design
- Easy-to-use integrated development environment (IDE) to program it with
- Plug-in shields that add features like displays and motor drivers that clip onto the top of the Arduino

All the programs for the Arduino used in this and later chapters are available for download from the book's accompanying web site (www.hackingelectronics.com).

The examples in this book are designed to work with both the Arduino Uno and the Arduino Leonardo. However, two of the projects, in the sections "How to Type Passwords Automatically" and "How to Make a USB Music Controller" (see Chapter 9), only work with Arduino Leonardo.

The Leonardo is the newer board. You may have some compatibility problems with this board and some Arduino shields. This includes any Ethernet Shield prior to the R3 Ethernet Shield. So, if you have an older Ethernet Shield, then the section "How to Control a Relay from a Web Page" will work on an Arduino Uno, but not a Leonardo, unless you have an R3 shield.

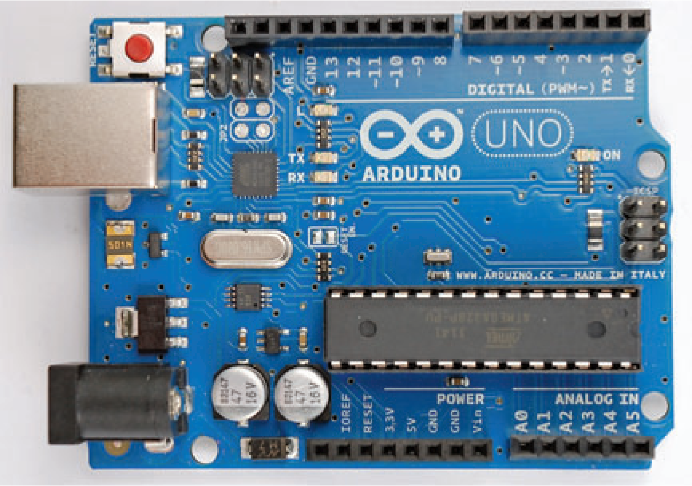

Figure 6-1 An Arduino Uno board

How to Set up Arduino (and Blink an LED)

To be able to program an Arduino, we first have to install the Arduino integrated development environment (IDE) on our computer. Arduino is available for Windows, Mac, and Linux.

You Will Need

Quantity	Item	Appendix Code
1	Arduino Uno/Leonardo	M2/M21
1	USB lead; Type B for Uno, Micro USB for Leonardo	

Setting Up Arduino

The first step is to download the software for your computer type from the official Arduino web site here: http://arduino.cc/en/Main/Software.

Once this is downloaded, you can find detailed instructions for the installation of each platform here: http://arduino.cc/en/Guide/HomePage.

One of the nice things about the Arduino is that to get started with it, all you need is an Arduino, a computer, and a USB lead to connect the two together. The Arduino can even be powered

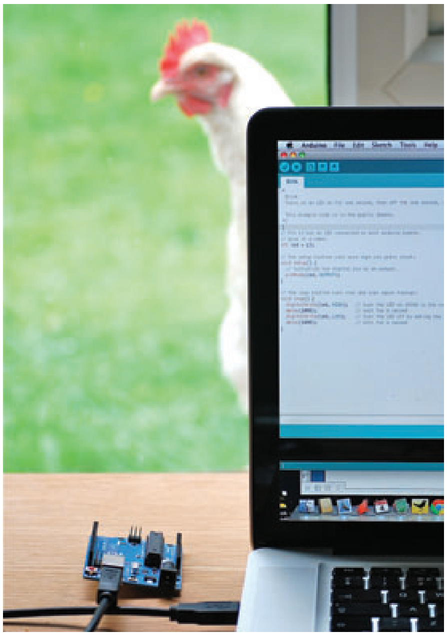

FIGURE 6-2 The Arduino, laptop, and chicken

over the USB connection to the computer. Figure 6-2 shows an Arduino Uno (the most common type of Arduino) connected to a laptop running the Arduino IDE.

To prove that the Arduino is working, we will program it to flash an LED that is on the Arduino board labeled "L" and hence known as the "L" LED.

Start by launching the Arduino IDE on your computer. Then, from the File menu (Figure 6-3), select Examples | 01.Basics | Blink.

In an attempt to make programming the Arduino sound less daunting to non-programmers, programs on the Arduino are referred to as "sketches." Before we can send the Blink sketch to your Arduino, we need to tell the Arduino IDE what type of Arduino we are using. The most common type is the Arduino Uno, and in this chapter we will assume that is what you have. So from the Tools | Board menu, select Arduino Uno (Figure 6-4).

As well as selecting the board type, we also need to select the port it is connected to. In Windows, this is easy because it is always COM3 or COM4 (see Figure 6-5). However, on a Mac or Linux, there will generally be more serial

devices. However, the Arduino IDE shows them with the most recently connected first, so your Arduino board should be at the top of the list.

To actually upload the sketch onto the Arduino board, click the Upload button on the tool bar. This is the second button on the toolbar, highlighted in Figure 6-6.

Once, you press the Upload button, a few things should happen. First, a progress bar will appear as the Arduino IDE first compiles the sketch (converts it into a suitable form for uploading). Then, the LEDs on the Arduino—labeled Rx and Tx—should flicker for a while.

Finally, the LED labeled L should start to blink. The Arduino IDE will also show a message that looks something like "Binary sketch size: 1,084 bytes (of a 32,256 byte maximum)." This means

Compiling sketch...

20 Arduino Uno on COM4

Figure 6-6 Uploading the Blink sketch

the sketch has used about 1kb of the 32k of flash memory available for programs on the Arduino.

Note that if you are using a Leonardo, you may have to keep the Reset button depressed until you see the message “Uploading…” in the Arduino software.

Modifying the Blink Sketch

It may be that your Arduino was already blinking when you first plugged it in. That is because the Arduino is often shipped with the Blink sketch already installed.

If this is the case, you might like to prove to yourself that you have actually done something by changing the blink rate. We will now examine the Blink sketch and see how we could change it to make it blink faster.

The first part of the sketch is just a comment, to tell someone looking at the sketch what it is supposed to do. This is not actual program code, and part of the preparation for the code being uploaded is for all such "comments" to be stripped out. Anything between "/*" and "*/" is ignored.

```
/*
  Blink
  Turns on an LED on for one second, then off for one
second, repeatedly.

  This example code is in the public domain.
 */
```

We then have a couple of individual line comments that start with //. Just like the block comments earlier, these are simply to inform us of what is happening. In this case, it helpfully tells us to use pin 13 as the pin we will flash. We have chosen that pin because on an Arduino Uno that pin is connected to the built-in "L" LED.

```
// Pin 13 has an LED connected on most Arduino boards.
// give it a name:
int led = 13;
```

The next part of the sketch is the "setup" function. Every Arduino sketch must have a "setup" function, and this function runs every time the Arduino is reset, either because (as the comment says) the reset button is pressed, or the Arduino is powered up.

```
// the setup routine runs once when you press reset:
void setup() {
  // initialize the digital pin as an output.
  pinMode(led, OUTPUT);
}
```

The structure of this text is a little confusing if you are new to programming. A function is a section of code that has been given a name (in this case, the name is "setup"). For now, simply use the text just cited as a template and understand that it must start with the first line "void setup() {". Afterward, you place each of the commands you want to issue on a line ending with ";", and then mark the end of the function with a "}" symbol.

In this case, the only command we expect the Arduino to carry out is to issue the "pinMode(led, OUTPUT)" command that not unsurprisingly sets that pin to be an output.

Next comes the juicy part of the sketch: the "loop" function.

Like the "setup" function, every Arduino sketch must have a "loop" function. Unlike "setup" which only runs once after a reset, the "loop" function runs continuously. That is, as soon as all its instructions have been done, it starts again.

In the "loop" function, we first turn on the LED by issuing the "digitalWrite (led, HIGH)" instruction. We then pause for a second by using the command "delay(1000)". The value is 1000 for 1000 milliseconds, or one second. We then turn the LED back off again, and delay for another second before the whole process starts over.

```
// the loop routine runs over and over again forever:

void loop() {
  digitalWrite(led, HIGH);   // turn the LED on (HIGH is the voltage level)
  delay(1000);               // wait for a second
  digitalWrite(led, LOW);    // turn the LED off by making the voltage LOW
  delay(1000);               // wait for a second
}
```

To modify this sketch to make the LED blink faster, change both occurrences of 1000 to 200. These changes are both in the "loop" function, so your function will now look like this:

```
void loop() {
  digitalWrite(led, HIGH);   // turn the LED on (HIGH is the voltage level)
  delay(200);               // wait for a second
  digitalWrite(led, LOW);    // turn the LED off by making the voltage LOW
  delay(200);               // wait for a second
}
```

If you try to save the sketch before uploading it, you will be reminded that it is a "read-only" example sketch, but the Arduino IDE will offer you the option to save it as a copy, which you can then modify to your heart's content.

You do not have to do this, of course. You can just upload the sketch unsaved, but if you do decide to save this or any other sketch, you will find that it then appears in the File | Sketchbook menu on the Arduino IDE.

So, either way, click the Upload button again. When the uploading is complete, the Arduino will reset itself and the LED should start to blink much faster.

How to Make an Arduino Control a Relay

The USB connection of an Arduino can be used for more than just programming the Arduino. You can also use it to send data between the Arduino and your computer. If we attach a relay to the Arduino, we could send a command from our computer to turn the relay on and off.

Relays

A relay (Figure 6-7) is an electromechanical switch. It's very old technology, but relays are cheap and very easy to use.

A relay is basically an electromagnet that closes switch contacts. The fact that the coil and the contacts are electrically isolated from one another makes relays great for things like switching home-powered devices on and off from something like an Arduino.

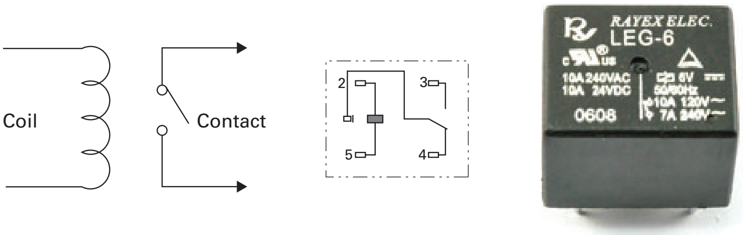
Whereas the coil of a relay is often energized by between 5V and 12V, the switch contacts can control high-power, high-voltage loads. For example, the relay photographed in Figure 6-7 claims a maximum current of 10A at 120V AC (household power) as well as 10A at 24V DC.

Arduino Outputs

Arduino outputs, and for that matter inputs, are referred to as "pins," even though if you look at the connectors along the sides of the Arduino, they are most definitely sockets rather than pins. The name harkens back to the pins on the microcontroller IC at the heart of the Arduino that were connected to the sockets.

Each of these "pins" can be configured to act as either an input or an output. When they are acting as an output, each pin can provide up to 40mA. This is more than enough to light

FIGURE 6-7 A relay



Relay Schemtic

Relay Package

A Relay

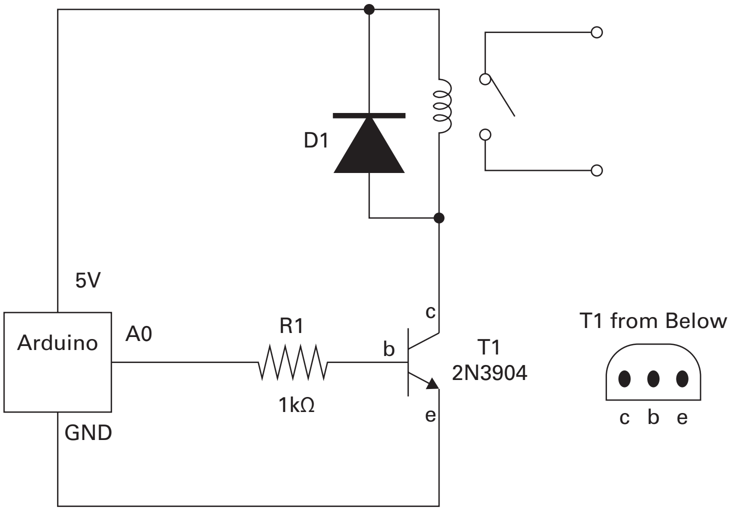


FIGURE 6-8 Schematic diagram of an Arduino-controlled relay

an LED, but not enough to energize a relay coil, which typically requires more like 100mA.

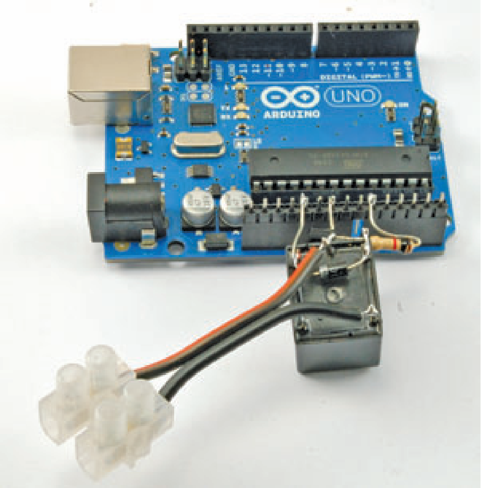
This is a problem we have already discussed. Since we want to use a small current to control a larger one, a good way to do this is by using a transistor.

Figure 6-8 shows a schematic diagram of what we are going to build.

We are using a transistor just like we did when we were controlling an LED. One difference in the schematic is that there is a diode across the relay coil. This is required because when you turn the relay off and the magnetic field in the coil collapses, you get a spike of voltage. The diode prevents this from damaging anything.

We are going to solder the components to the relay and then attach the necessary leads to a header strip that will plug into the Arduino (Figure 6-9). The header strip has 15 pins and spans both of the connector sockets on the side of the Arduino closer to the microcontroller chip. There is a gap between the two connector strips, so one of the header pins will not actually be fitted into a socket.

FIGURE 6-9 The Arduino relay interface



You Will Need

Quantity	Names	Item	Appendix Code
1		Arduino Uno/Leonardo	M2/M21
1		USB lead; Type B for Uno, Micro USB for Leonardo	
1		Transistor 2N3904	K1, S1
1	R1	1kΩ 0.25-W resistor	K2
1	D1	1N4001 diode	K1, S5
1	Relay	5V Relay	H16
1		* Pin header 15-way	K1, H4
1		Two-way screw terminal	H5

* Pin headers are usually supplied in long lengths designed to be snapped into whatever number of connections you need.

Construction

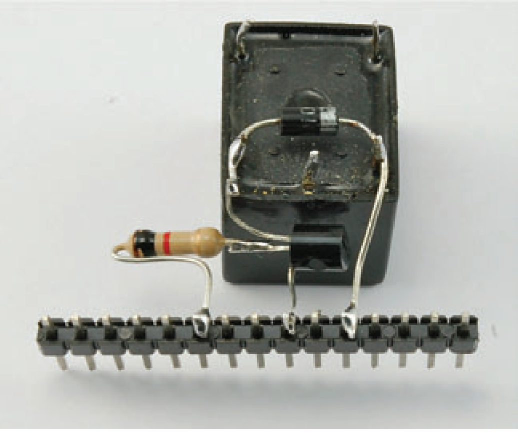
Figure 6-10 shows how the components are attached. First, solder the diode to the relay coil contacts. These are the two pins on the far side of the relay that have three pins more or less in a row. The stripe on the diode should be to the right, as shown in Figure 6-10.

After soldering the diode across the relay coils, bend out the leads of the transistor and position it as shown in Figure 6-10 with the flat side against the relay. Shorten the base (middle) lead of the transistor, shorten the leads on the resistor and attach it to the base lead.

Finally, solder the three leads to the connector strip. The resistor lead should go to the 6th lead from the left, the emitter of the transistor to the 9th from the left, and the diode lead to the 11th from the left.

Before we attach leads to the relay contacts, we can test our work using a multimeter in Continuity mode, so attach the header pins to the Arduino as shown in Figure 6-9 and clip one lead of the multimeter (on Continuity mode) to the middle contact of the relay (in between the diode leads). Attach the other lead of the multimeter to each of the two unconnected contacts on the relay. One will buzz and the other will not. Attach the lead to

Figure 6-10 Wiring the relay interface



the one that does not cause the multimeter to beep—this is the n.o. (normally open contact).

Load the sketch "relay_test" into Arduino and upload it to the Arduino board. When the Arduino restarts, you should find that every two seconds the relay will flip from being open to being closed.

Software

The sketch for this is much the same as the Blink sketch.

```
// relay_test

int relayPin = A0;

void setup()
{
  pinMode(relayPin, OUTPUT);
}

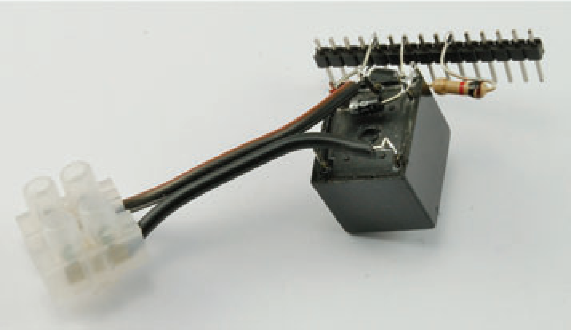
void loop()
{
  digitalWrite(relayPin, HIGH);
  delay(2000);
  digitalWrite(relayPin, LOW);
  delay(2000);
}
```

The only real difference is that we are using pin A0 rather than pin 13. Arduino has a feature that allows you to use the analog input pins A0 to A5 as digital inputs or outputs as well as analog inputs, but you have to put the letter A in front of them when using them as digital pins.

If all is well, then to make it easier to attach things to the relay contacts, we can solder some wires to them and use a two-way screw terminal block (Figure 6-11).

The relay module can be used to control all sorts of things. It can be used to control 110 or 240V home-powered devices, but be very sure you know what you are doing before you attempt that. If you plan to do this, everything must

FIGURE 6-11 Attaching leads to the relay contacts



be insulated and the whole project enclosed in a plastic box, especially since touching a "hot" wire can and does kill many people every year.

In the next section, you will hack an electrical toy so it can be turned on and off using the Arduino and relay module you have just built.

How to Hack a Toy for Arduino Control

The great thing about a relay is that it behaves just like a switch. This means that if you have something you want to turn on and off from your Arduino and that item has a switch, then all you need to do is solder some wires to the switch and attach them to the relay. This would allow both the relay and the switch to turn the device on and off. But if you do not want to keep the original switch, it can be removed, as it will be in this case.

The toy that the author chose to hack is a little electric bug (Figure 6-12).

Figure 6-12 The hapless electric bug awaiting dissection

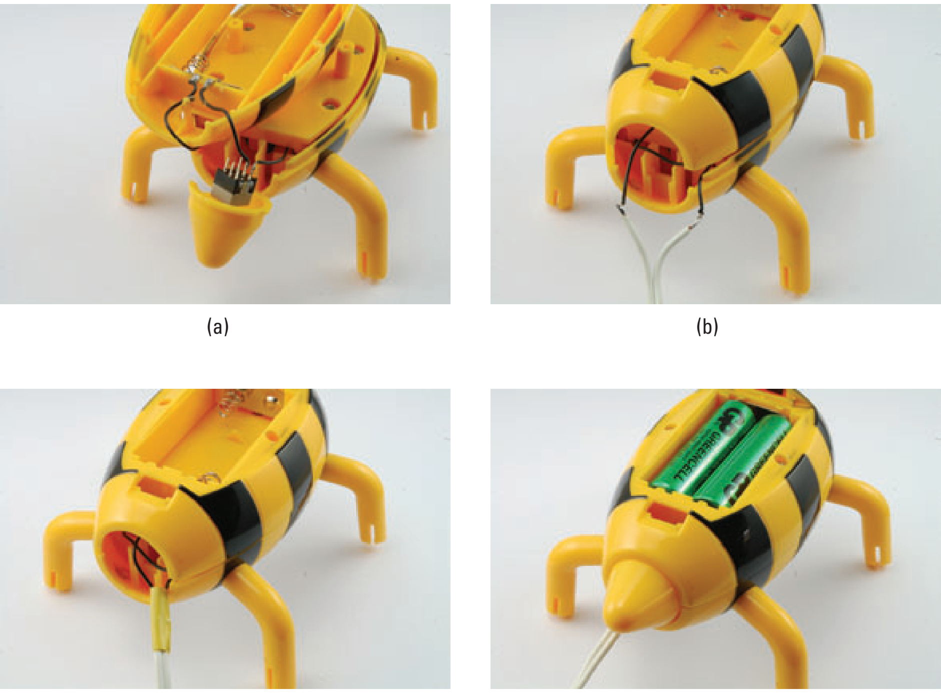
You Will Need

As well as the relay module built in the section "How to Make an Arduino Control a Relay," you will also need the following items.

Quantity	Item	Appendix Code
1	Arduino Uno/Leonardo	M2/21
1	USB lead; Type B for Uno, Micro USB for Leonardo	
1	An electric toy (battery-powered) with an on–off switch	
1	Twin multi-core wire	

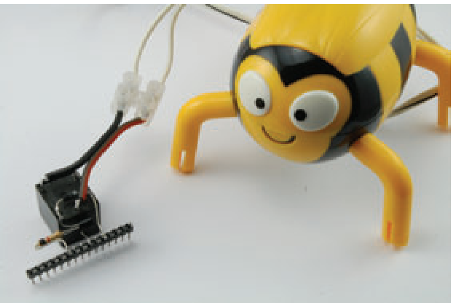
Construction

Taking the toy apart, you can see the connections to the switch (Figure 6-13a). De-solder the switch and attach wires to the leads that used to go to the switch (Figure 6-13b). You should always put insulating tape around the bare wires to prevent accidental shorts (Figure 6-13c).



(a) (b)

(c) (d)



(e)

Figure 6-13 Hacking the toy

The toy can then be assembled with the wire leaving through a gap in the case (Figure 6-13d). If there is no suitable gap, you will probably need to drill a hole.

Finally, the toy is ready to use, so plug the relay interface into the Arduino and connect the wires to its screw terminals (Figure 6-13e). If the test sketch is still installed, you should find that the toy repeatedly turns on for a couple of seconds, and then turns back off again.

This is okay, but not terribly useful. We will use another sketch that will allow us to send commands to the Arduino from your computer. The sketch is called “relay_remote”.

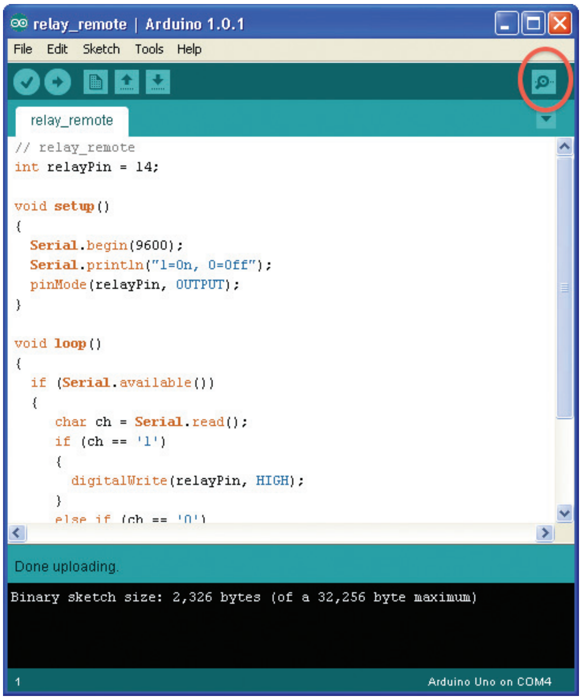
Upload this sketch to the Arduino. Then, open the Serial Monitor by clicking the button on the right-hand side of the Arduino IDE (circled in Figure 6-14).

The Serial Monitor

The Serial Monitor is part of the Arduino IDE that allows you to send and receive data between your computer and the Arduino board (Figure 6-15).

At the top of the Serial Monitor is an area where we can type commands. When we click the Send button, these are sent to the Arduino. We can see any messages that the Arduino has sent in the area below this.

Try this out by typing in the number 1 and clicking Send. This should start your toy. Entering "0" should turn it off again.



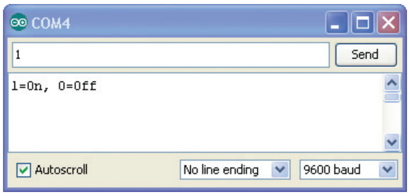
```
// relay_remote
int relayPin = 14;

void setup()
{
  Serial.begin(9600);
  Serial.println("1=On, 0=Off");
  pinMode(relayPin, OUTPUT);
}

void loop()
{
  if (Serial.available())
  {
     char ch = Serial.read();
     if (ch == '1')
     {
       digitalWrite(relayPin, HIGH);
     }
     else if (ch == '0')
```

```
Done uploading.
Binary sketch size: 2,326 bytes (of a 32,256 byte maximum)
```

FIGURE 6-14 Opening the Serial Monitor



1

```
1=On, 0=Off
```

☑ Autoscroll

No line ending

9600 baud

FIGURE 6-15 The Serial Monitor

Software

Let's now look at the sketch.

```
// relay_remote
int relayPin = A0;

void setup()
{
  Serial.begin(9600);
  Serial.println("1=On, 0=Off");
  pinMode(relayPin, OUTPUT);
}

void loop()
{
  if (Serial.available())
  {
     char ch = Serial.read();
     if (ch == '1')
     {
       digitalWrite(relayPin, HIGH);
     }
     else if (ch == '0')
     {
       digitalWrite(relayPin, LOW);
     }
  }
}
```

Notice that the "setup" function now has two new commands in it.

```
Serial.begin(9600);
Serial.println("1=On, 0=Off");
```

The first of these starts serial communications over the serial port at 9600 baud. The second sends the prompt message, so that we know what to do when the Serial Monitor opens.

The "loop" function first uses the function "Serial.available()" to check if there is any communication from the computer waiting to be processed. If there is, then this is read into a character variable.

We then have two if statements. The first checks to see if the character is a "1", and if it is, it turns on the toy. If, on the other hand, the character read is a "0", it turns it off.

We have made a little bit of a leap from our first flashing sketch, and if you need more help understanding how the sketch works, you might consider buying the book *Programming Arduino: Getting Started with Sketches* by this author.

How to Measure Voltage with an Arduino

The pins labeled A0 to A5 on an Arduino are analog inputs. That is, you can use them to measure voltage. To demonstrate this, you will use the variable resistor (trimpot) as a voltage divider connected to A3 (Figure 6-16).

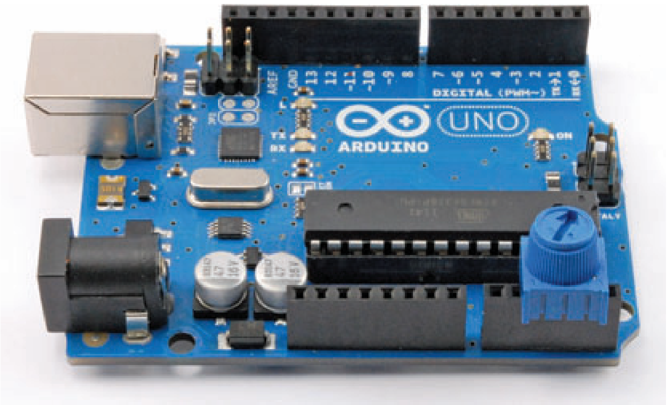


FIGURE 6-16 A variable resistor and Arduino

If you skipped the section on voltage dividers in Chapter 3 titled “How to Use Resistors to Divide a Voltage,” you probably should go back and have a quick look now.

You Will Need

To try this example, you will need the following items.

Quantity	Names	Item	Appendix Code
1		Arduino Uno/Leonardo	M2/M21
1		USB lead; Type B for Uno, Micro USB for Leonardo	
1	R1	10kΩ variable resistor	K1, R1

Construction

The construction of this project is very simple. There is no actual soldering involved, we will just push the three pins of the variable resistor into the Arduino sockets A2, A3, and A4. Figure 6-17 shows the schematic diagram for this.

You may be wondering how this will work, since you would normally expect the top of the variable resistor to be connected to 5V and the bottom to GND. Well, since a 10kΩ resistor at 5V will only be allowing 0.5mA of current to flow, we can use pins A2 as digital outputs and set A2 to 0V and A4 to 5V.

Plug the variable resistor into the Arduino so that the middle slider connection is to pin A3 and the pins on either side are connected to A2 and A4.

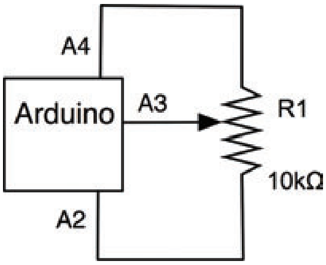

FIGURE 6-17 Schematic diagram—measuring voltage with an Arduino

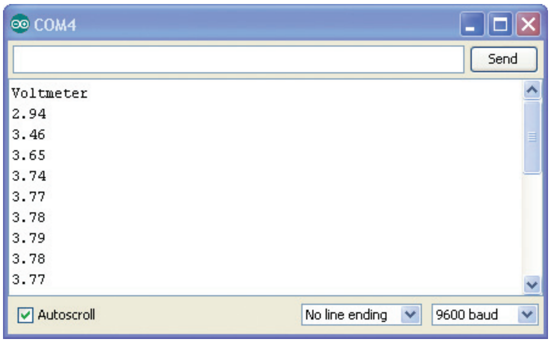
Software

Load the sketch “voltmeter” into the Arduino IDE and then program your Arduino board with it. Open the Serial Monitor and you should see something like Figure 6-18.

Try twiddling the knob from one end of the range to the other. You should find that you can set the voltage to anything between 0 and 5V.



```
Voltmeter
2.94
3.46
3.65
3.74
3.77
3.78
3.79
3.78
3.77
```

☑ Autoscroll

FIGURE 6-18 The Serial Monitor showing voltage at A3

```
// voltmeter

int voltsInPin = 3;
int gndPin = A2;
int plusPin = A4;
```

```
void setup()
{
  pinMode(gndPin, OUTPUT);
  digitalWrite(gndPin, LOW);
  pinMode(plusPin, OUTPUT);
  digitalWrite(plusPin, HIGH);
  Serial.begin(9600);
  Serial.println("Voltmeter");
}

void loop()
{
  int rawReading = analogRead(voltsInPin);
  float volts = rawReading / 204.8;
  Serial.println(volts);
  delay(200);
}
```

The sketch defines the pins as usual. Note that when referring to the analog input pins for use as analog inputs (as with “voltsInPin”), we just use the pin number. So for A3 we specify just 3. However, because we are using A2 and A4 as digital outputs, we have to add the letter A to the front.

The “setup” function sets the pin modes, but also sets “gndPin” and “plusPin” to LOW and HIGH, respectively, before starting serial communication and sending a welcome message.

Inside the loop, we use “analogRead” to give us a raw value of between 0 and 1023, where 0 means 0V and 1023 means 5V. To convert this into an actual voltage, we need to divide it by 204.8 (1023/5). In dividing a raw reading that is an integer (whole number) by a decimal number of 204.8 (called floats in Arduino), the result will be a float, and so we specify the type of the “volts” variable to be “float”.

Finally, we print out the voltage and then wait 200 milliseconds before we take the next reading. We don’t have to wait before taking the next reading, it just stops the readings from flying up the screen too fast to read.

In the next section, we will use the same hardware with the addition of an external LED and a slightly different sketch to change the rate at which an external LED flashes.

How to Use an Arduino to Control an LED

There are three useful things to be learned here. The first is how to make an Arduino drive an LED. The second is how to control the rate of flashing using a reading from a variable resistor, and finally we will show how to use the Arduino to control the power going to the LED and thus determine its brightness (Figure 6-19).

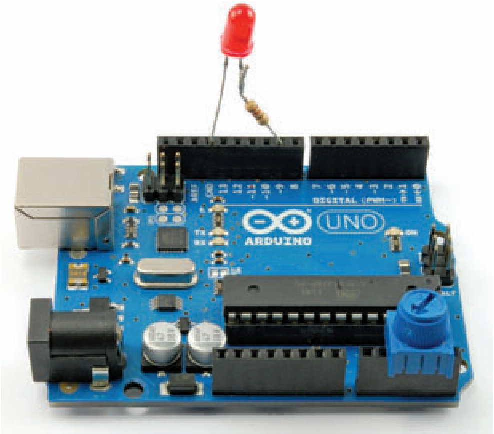


FIGURE 6-19 An Arduino, variable resistor, and LED

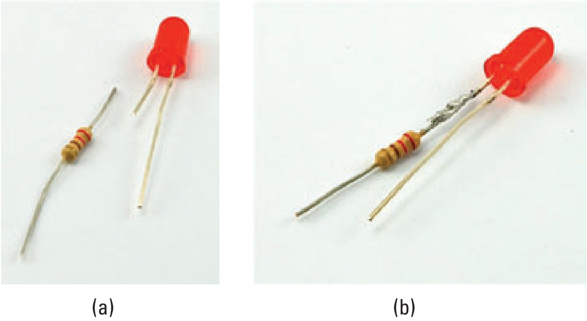
You Will Need

To try this example, you will need the following items.

Quantity	Names	Item	Appendix Code
1		Arduino Uno/Leonardo	M2/M21
1		USB lead; Type B for Uno, Micro USB for Leonardo	
1	R1	10kΩ variable resistor	K1, R1
1	R2	220Ω Resistor	K2
1	D1	LED	K1

Construction

As we discussed in Chapter 4, LEDs need a resistor to stop them drawing too much current. This means we cannot just push one straight into an output pin of an Arduino. So, we are going to start by taking an LED and resistor, shortening the leads, soldering them together and making an LED resistor combo that we can just plug into our Arduino. Figure 6-20 shows the steps involved in making this.



(a) (b)

FIGURE 6-20 Making an LED resistor combo

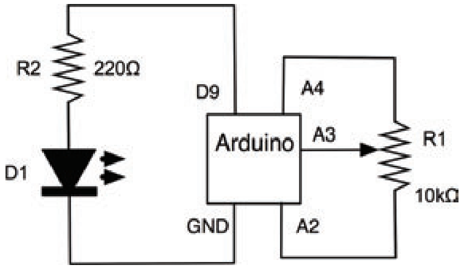


FIGURE 6-21 Schematic for an LED, Arduino, and a variable resistor

To avoid confusion, put the resistor in the anode (positive and longer) lead and keep the combined lead the longer lead, so you know it is the positive end of the combo.

The schematic diagram for the arrangement is shown in Figure 6-21.

We will use pin 9 as a digital output for the LED. The other end of the LED combo being connected to a convenient GND connection.

Keep this Arduino-friendly LED combo. You will use it again in several later sections.

Software (Flashing)

You will use two different sketches with this arrangement of hardware. The first uses the variable resistor to control the speed of the flashing, while the second will control the brightness of the LED.

Attach the LED resistor combo, as shown in Figure 6-19, and load the sketch "variable_led_flash" onto your Arduino board. You should find that turning the knob controls the rate at which the LED flashes.

```
// variable_led_flash

int voltsInPin = 3;
int gndPin = A2;
int plusPin = A4;
int ledPin = 9;

void setup()
{
  pinMode(gndPin, OUTPUT);
  digitalWrite(gndPin, LOW);
  pinMode(plusPin, OUTPUT);
  digitalWrite(plusPin, HIGH);
  pinMode(ledPin, OUTPUT);
}

void loop()
{
  int rawReading = analogRead(voltsInPin);
  int period = map(rawReading, 0, 1023, 100, 500);
  digitalWrite(ledPin, HIGH);
  delay(period);
  digitalWrite(ledPin, LOW);
  delay(period);
}
```

The sketch is quite similar to that in the previous section; however, we no longer use the Serial Monitor, so all that code is gone. We do need to define a new pin "ledPin" to use for the LED.

The "loop" function still reads the raw value from the analog pin A3, but it then uses the "map" function to convert the "rawReading" value of between 0 to 1023 to a range of 100 to 500.

The "map" function is a standard Arduino command that adjusts the range of the value passed in as the first parameter. The second and third parameters are the range of the raw value, while the fourth and fifth are the desired range you want to compress or expand the value into.

We then flash the LED using this number (100 to 500) as the delay between turning the LED on and off. The end result of this is that the LED will flash faster the closer A3 is to 0V.

Software (Brightness)

We can use exactly the same hardware, but with different software to control the brightness of the LED instead of its rate of flashing. This will use the Arduino "analogWrite" function to vary the power going to the pin. This feature is only available for those pins marked with a "~" on the Arduino board. Fortunately, we thought ahead and chose such a pin to connect the LED to.

These pins can use a technique called pulse-width modulation (PWM) to control how much power goes to the output. This works by sending out a series of pulses, around 500 times per second. These pulses may be high for only a short time, in which case little power is delivered, or high until it's nearly time for the next pulse, in which case lots of power is delivered.

In the case of the LED, this means that in each cycle, the LED is either off, on for some of the time, or on the whole time. Our eyes cannot keep up with such a fast-changing event, so it just appears that the brightness of the LED varies.

Load the sketch "variable_led_brightness" onto your Arduino. You should find that, now, the variable resistor controls the brightness of the LED rather than its rate of flashing.

Most of the sketch is the same as the previous one, the difference lies in the "loop" function.

```
void loop()
{
  int rawReading = analogRead(voltsInPin);
  int brightness = rawReading / 4;
  analogWrite(ledPin, brightness);
}
```

The function “analogWrite” expects a value between 0 and 255, so we can take our raw analog reading of between 0 and 1023 and divide it by 4 to put it into roughly the right range.

How to Play a Sound with an Arduino

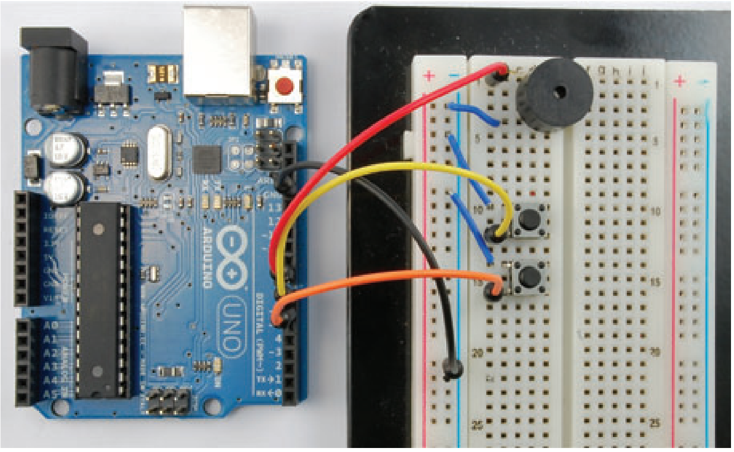
The first Arduino sketch we tried at the start of this chapter flashed an LED on and off. If we turn a digital output pin on and off much faster than this, we can drive a sounder to create a sound. Figure 6-22 shows a simple sound generator that plays one of two notes when a button is pressed.

You Will Need

To have your Arduino make sounds, you will need the following items.

Quantity	Names	Item	Appendix Code
1		Arduino Uno/Leonardo	M2/M21
1		USB lead; Type B for Uno, Micro USB for Leonardo	
2	S1, S2	Miniature push switches	K1
1	Sounder	Small piezo sounder	M3
1		Breadboard	T5
		Jumper wires or solid-core wire	T6

Figure 6-22 A simple Arduino tone generator



Construction

Figure 6-23 shows the schematic for the tone generator, while Figure 6-24 displays the breadboard layout.

Make sure the push switches are the right way around. They should be positioned so the pins extend out of the sides rather than the top and bottom. The piezo sounder may have one pin indicated as positive. Position this at the top of the breadboard.

Attach the components as shown and connect the jumper leads to the Arduino.

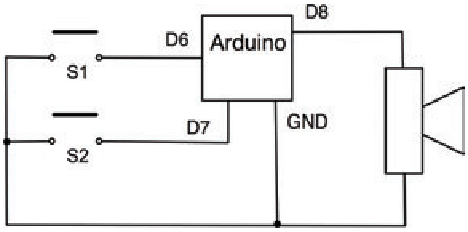


FIGURE 6-23 Schematic diagram for the tone generator

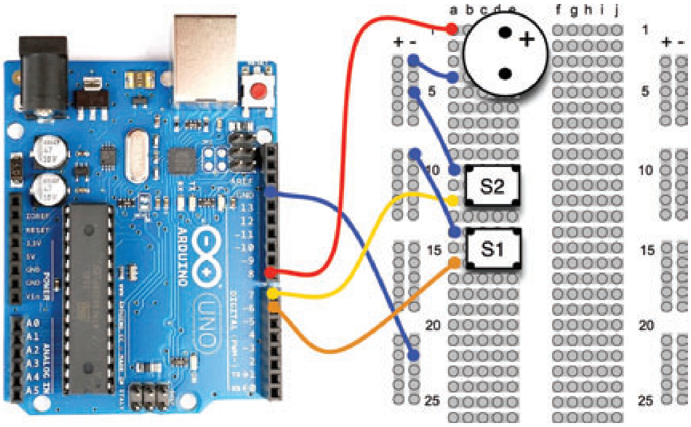

FIGURE 6-24 Breadboard layout for the tone generator

Software

The sketch is quite straightforward and follows what should be a familiar pattern by now.

```
// arduino_sounds

int sw1pin = 6;
int sw2pin = 7;
int soundPin = 8;

void setup()
{
  pinMode(sw1pin, INPUT_PULLUP);
  pinMode(sw2pin, INPUT_PULLUP);
  pinMode(soundPin, OUTPUT);
}

void loop()
{
  if (! digitalRead(sw1pin))
  {
    tone(soundPin, 220);
  }
  else if (! digitalRead(sw2pin))
  {
    tone(soundPin, 300);
  }
  else
  {
    noTone(soundPin);
  }
}
```

First, we define the variables for the pins. The switches will be connected to "sw1pin" and "sw2pin". These will be digital inputs, while the "soundPin" will be a digital output.

Note that in the setup function for the switch pins, we use the command "pinMode" with the parameter INPUT_PULLUP. This sets the pin to be an input, but also enables a "pull-up" resistor built into the Arduino, which keeps the input pin HIGH, unless we pull it LOW by pressing the button.

It is because the input pins are normally high that in the "loop" function, when we are checking to see if a button is pressed, we have to use the "!" (logical not). In other words, the following will only sound the tone if the digital input pin "sw1pin" is LOW.

```
if (! digitalRead(sw1pin))
{
tone(soundPin, 220);
}
```

The "tone" function is a useful built-in Arduino function that plays a tone on a particular pin. The second parameter is the frequency of the tone in Hertz (cycles per second).

If no key is pressed, then the function "noTone" is called and stops any tone that is playing.

How to Use Arduino Shields

The success of Arduino had been in no small part due to the wide range of plug-in shields that add useful features to a basic Arduino board. A shield is designed to fit into the header sockets of the main Arduino board. Most shields will then pass through these connections in another row of header sockets, making it possible to construct stacks of shields with an Arduino at the bottom. Shields that have, say, a display on them, will not normally pass through in this way. You also need to be aware that if you stack shields like this, you need to make sure there are no incompatibilities, such as two of the shields using the same pin. Some shields get around this problem by providing jumpers to add some flexibility to pin assignments.

Shield	Description	URL
Motor	Ardumoto shield. Dual H-bridge bidirectional motor control at up to 2A per channel.	www.sparkfun.com/products/9815
Ethernet	Ethernet and SD card shield.	http://arduino.cc/en/Main/ArduinoEthernetShield
Relay	Controls four relays. Screw terminals for relay contacts.	www.robotshop.com/seeedstudio-arduino-relay-shield.html
LCD	16 × 2 character alphanumeric LCD shield with joystick.	www.freetronics.com/products/lcd-keypad-shield

TABLE 6-1 Some Commonly Used Shields

The web site http://shieldlist.org/ will tell you which pins are used by any particular shield.

There are shields available for almost anything you could want an Arduino to do. They range from relay control to LED displays and audio file players.

Most of these are designed with the Arduino Uno in mind, but are also usually compatible with the bigger Arduino Mega and the new Arduino Leonardo.

For an encyclopedic list, that includes useful technical details about the pin usage of these shields, it can be found at http://shieldlist.org/.

Some of the author's favorite shields are listed in Table 6-1.

How to Control a Relay from a Web Page

By using an Ethernet Shield and connecting it to your home hub, you can turn your Arduino into a tiny web server. Since it is still an Arduino, you can still attach electronics to it. So, by using the hacked toy we made in the section "How to Hack a Toy for Arduino Control" and a web interface on the Arduino, we can control our toy over our local network, or if we open up our firewall from the Internet!

Figure 6-25 shows the toy attached to the shield and Arduino along with the browser interface that we will use to control it—first on our computer (Figure 6-25b) and then from a smartphone (Figure 6-25c).

(c)

FIGURE 6-25 A hacked toy controllable over the network

You Will Need

To make your web-controlled toy, you will first need to complete the section titled "How to Hack a Toy for Arduino Control." In addition, you will need the following items:

Quantity	Item	Appendix Code
1	Arduino Ethernet Shield	M4
1	Ethernet patch cable	T6
1	9V or 12V 500mA Power Supply	M1

Note that this project will only work with the Arduino Leonardo if the Ethernet Shield is the latest R3 Ethernet Shield. If you have an older Ethernet Shield, you will either need to buy a new Ethernet Shield or use an Arduino Uno.

Construction

In this project, the Arduino is powered from an external power supply rather than the USB connection to the computer. There are two reasons for this. One is that the Ethernet Shield will not operate just from USB power, and the other is that once the Arduino has been programmed—there is no need for it to be connected to your computer, so it may as well be powered from a separate adapter.

The wiring diagram for the project is shown in Figure 6-26.

Connect everything up as shown in Figure 6-26 and load the sketch "web_relay" into the Arduino IDE. Don't upload it onto the Arduino itself just yet. There are some configuration changes we need to make first.

Network Configuration

If you look at the top of the sketch, you will see the lines:

```
byte mac[] = { 0xDE, 0xAD, 0xBE, 0xEF, 0xFE, 0xED };
byte ip[] = { 192, 168, 1, 30 };
```

The first of these, the "mac address" just has to be unique amongst all the devices connected to your network. Note that some of the newer Ethernet Shields have a Mac address printed on them. If you have one of these boards, enter that here. The second one is the IP address. Most devices you connect to your home network will have IP addresses assigned to them automatically by a process called DHCP. That's just fine if you don't really need to know the IP address of your shield and don't mind it changing (say, when using the shield to act like a browser rather than a web server). But in this project, the Arduino and Ethernet Shield are going to act like a web server, so we need to know what the IP address is so we can type it into the address bar of a browser.

You will manually define an IP address. This cannot be any four numbers; they must be numbers that qualify as being internal IP addresses and fit in the range of IP addresses expected by your home router. Typically, the first three numbers will be something like 10.0.1.*x* or 192.168.1.*x*, where *x* is some number between 0 and 255. Some of these IP addresses will be in use by other devices on your network. To find an unused but valid IP address, connect to the administration page for your home router and look for an option that says DHCP. You should somewhere find a list of devices and their IP addresses similar to that in Figure 6-27. Select a final number to use in your IP address. In this case, 192.168.1.30 looked like a good bet and indeed it worked fine.

Set the IP address in the sketch and upload it to your Arduino board.

Testing

Open up a browser on your computer, tablet, or smartphone and navigate to the IP address. If you used the same IP address as the author, that would be http://192.168.1.30. You should then see the web page of Figure 6-25b and 6-25c displayed.

Click the On button and the relay should click on, turning the hacked toy on. The page will then reload in the browser. Clicking "Off" will turn the relay off again.

Figure 6-27 Selecting an IP address to use

Software

This sketch is one of the most complicated in the book. However, it is one that can easily be used as a template for other hacks using an Arduino as a web server.

Let's break this sketch down and look at it a section at a time.

```
// web_relay

#include <SPI.h>
#include <Ethernet.h>

// MAC address just has to be unique. This should work
byte mac[] = { 0xDE, 0xAD, 0xBE, 0xEF, 0xFE, 0xED };
// The IP address will be dependent on your local
network:
```

```
byte ip[] = { 192, 168, 1, 30 };
EthernetServer server(80);
int relayPin = A0;
char line1[100];
```

Two libraries have to be included for use with the Ethernet Shield: “SPI” and “Ethernet.” Libraries contain a useful collection of functions for, say, a shield. They greatly simplify the writing of sketches as they can just make use of the library functions.

The “SPI” library is for a kind of serial communication that the Arduino uses to send instructions to the Ethernet Shield, and the “Ethernet” library defines some useful functions for us to use with the Ethernet Shield.

After the two variables that define the Mac address and IP address, the next command creates a new “EthernetServer” object that is used every time we want to do something with the Ethernet. We then define the “relayPin” to use and also create a line buffer of 100 characters that is used later in the code when reading the header that arrives from a browser when you navigate to the page being served by the Arduino.

```
void setup()
{
  pinMode(relayPin, OUTPUT);
  Ethernet.begin(mac, ip);
  server.begin();
}
```

The setup function initializes the Ethernet library using the Mac and IP addresses that we set earlier. It also sets the pin mode of the “relayPin” to be an OUTPUT.

```
void loop()
{
  EthernetClient client = server.available();
  if (client)
  {
    while (client.connected())
    {
      readHeader(client);
      if (! pageNameIs("/"))
      {
        client.stop();
        return;
      }
      digitalWrite(relayPin, valueOfParam('a'));
```

```
        client.println("HTTP/1.1 200 OK");
        client.println("Content-Type: text/html");
        client.println();

        // send the body
        client.println("<html><body>");
        client.println("<h1>Relay Remote</h1>");

        client.println("<h2><a href='?a=1'/>On</a></h2>");
        client.println("<h2><a href='?a=0'/>Off</a></h2>");
        client.println("</body></html>");

        client.stop();
      }
    }
  }
```

The loop function is responsible for servicing any requests that come to the web server from a browser. If a request is waiting for a response, then calling "server.available" will return us a "client". If client exists (tested by the first "if" statement), we can then determine if it is connected to the web server by calling "client.connected".

We will come to the "readHeader" function later. This function and "pageNameIs" are used to determine that the browser is actually contacting the page for setting the relay. This is because browsers will often send two requests to a server page, one to try and find an icon for the web site, and a second to the page itself. This code allows us to ignore the icon request.

The next line sets the relay pin using "digitalWrite". The value it sets the output to is whatever value the request parameter "a" is set to. This will be either "1" or "0".

The next three lines of code print out a return header. This just tells the browser what type of content to display. In this case, just HTML.

Once the header has been written, it simply remains to write the remaining HTML back to the browser. This must include the usual "<html>" and "<body>" tags, and also includes a "<h1>" header tag and two "<h2>" tags that are also hyperlinks to this same page, but with the request parameter "a" set to either "0" or "1".

Finally, "client.stop" tells the browser that the message is complete and the browser will display the page.

```
void readHeader(EthernetClient client)
{
  // read first line of header
  char ch;
  int i = 0;
  while (ch != '\n')
  {
    if (client.available())
    {
      ch = client.read();
      line1[i] = ch;
      i ++;
    }
  }
  line1[i] = '\0';
  Serial.println(line1);
}
```

The final three functions in the sketch are general-purpose functions that I tend to use over and over again when making an Arduino web server like this.

The first, “readHeader”, reads the header of the request coming from the browser into the buffer “line”. We can then use this in the next two functions.

```
boolean pageNameIs(char* name)
{
   // page name starts at char pos 4
   // ends with space
   int i = 4;
   char ch = line1[i];
   while (ch != ' ' && ch != '\n' && ch != '?')
   {
     if (name[i-4] != line1[i])
     {
       return false;
     }
     i++;
     ch = line1[i];
   }
   return true;
}
```

The function “pageNameIs” returns true if the page name part of the header matches the argument supplied. This is what we use in the "loop" function to ignore the icon request from the browser.

```
int valueOfParam(char param)
{
  for (int i = 0; i < strlen(line1); i++)
  {
    if (line1[i] == param && line1[i+1] == '=')
    {
      return (line1[i+2] - '0');
    }
  }
  return 0;
}
```

The "valueOfParam" lets you read the value of the request parameter supplied as an argument. This is much more restricted than the kind of request parameter you will be used to if you have done any web programming. First, the request parameter name must be a single character, and second, its value must be a single digit between 0 and 9. The function will return the value or 0 if there is no parameter of that name.

This is one of those projects that can be adapted for all sorts of purposes.

How to Use an Alphanumeric LCD Shield with Arduino

Another commonly used Arduino shield is the LCD shield (Figure 6-28).

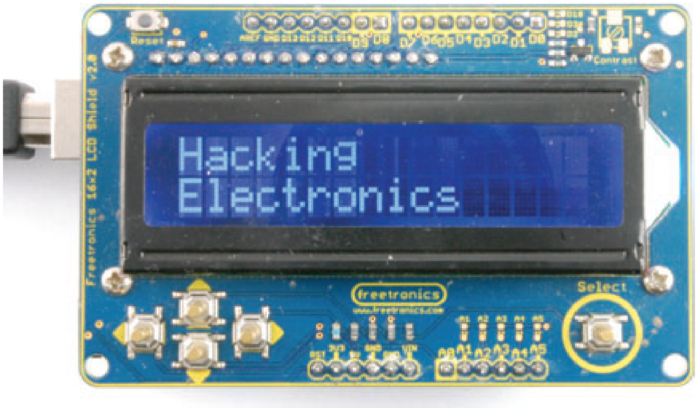

FIGURE 6-28 An LCD shield

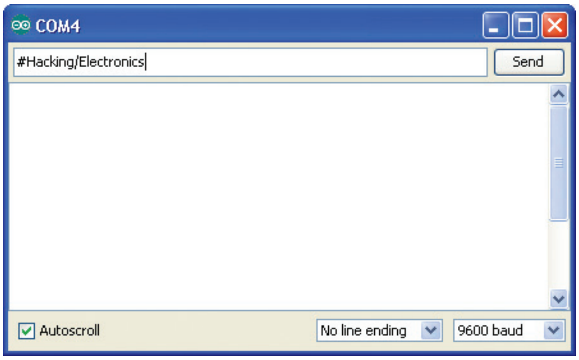


#Hacking/Electronics

☑ Autoscroll

No line ending

9600 baud

FIGURE 6-29 Sending a message with the Serial Monitor

There are many different shields available and most use an LCD module based on the HD44780 LCD driver chip. The model used here is the Freetronics LCD and Keypad Shield (www.freetronics.com). Most other LCD projects will work with this example code, but you may have to change the pin allocations (discussed later).

This project lets you send a short message (the display is only two lines of 16 characters) using the Serial Monitor (Figure 6-29).

You Will Need

To experiment with an LCD display, you will need the following items.

Quantity	Item	Appendix Code
1	Arduino Uno	M2
1	USB Type A to Type B (as commonly used for USB printers)	
1	LCD Shield	M18

Construction

There is really not very much to construct here. Just plug the LCD shield onto the Arduino and plug in the Arduino to your computer via a USB port.

Software

The software is pretty straightforward too. Again, most of the work is done in the library.

```
// LCD_messageboard

#include <LiquidCrystal.h>

// LiquidCrystal display with:
// rs on pin 8
// rw on pin 11
// enable on pin 9
// d4-7 on pins 4-7
LiquidCrystal lcd(8, 11, 9, 4, 5, 6, 7);

void setup()
{
  Serial.begin(9600);
  lcd.begin(2, 16);
  lcd.clear();
  lcd.setCursor(0,0);
  lcd.print("Hacking");
  lcd.setCursor(0,1);
  lcd.print("Electronics");
}

void loop()
{
  if (Serial.available())
  {
    char ch = Serial.read();
    if (ch == '#')
    {
      lcd.clear();
    }
    else if (ch == '/')
    {
      lcd.setCursor(0,1);
    }
    else
    {
      lcd.write(ch);
    }
  }
}
```

If you are using a different LCD shield, then check the specification to see which pins it uses for what. You may need to modify the line:

```
LiquidCrystal lcd(8, 11, 9, 4, 5, 6, 7);
```

The parameters to this are the pins that the shield uses for (rs, rw, e, d4, d5, d6, d7). Note that not all shields use the rw pin. If this is the case, just pick the number of a pin not being used for anything else.

The loop reads any input, and if it is a # character, it clears the display. If it is a "/" character, it moves to the second row; otherwise, it just displays the character that was sent.

For example, to send the text displayed in Figure 6-28, you would enter the following into the Serial Monitor:

```
#Hacking/Electronics
```

Notice that the LCD library provides you with the "lcd .setCursor" function to set the position for the next text to be written. The text is then written using the "lcd.write" function.

How to Drive a Servo Motor with an Arduino

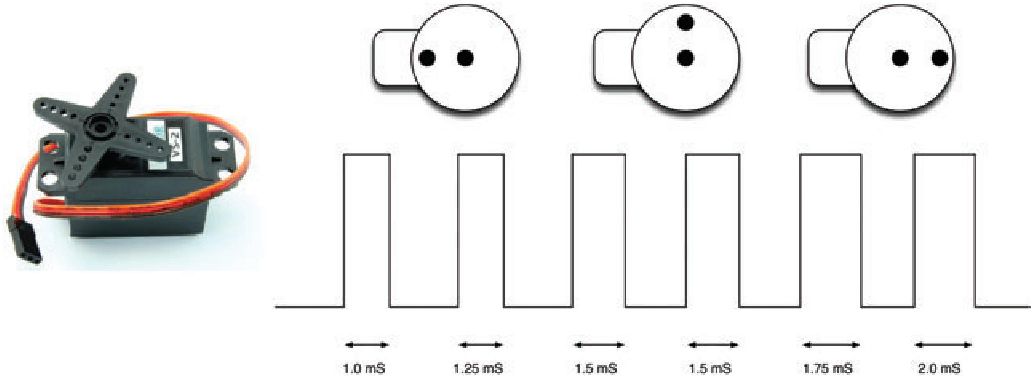
Servo motors are a combination of motor, gearbox, and sensor that are often found in remote-controlled vehicles to control steering or the angles of surfaces on remote-controlled airplanes and helicopters.

Unless they are special-purpose servo motors, servo motors do not rotate continuously. They usually only rotate through about 180 degrees, but can be accurately set to any position by sending a stream of pulses.

Figure 6-30 displays a servo motor and shows how the length of the pulses determines the position of the servo.

A servo will have three connections: GND, a positive power supply (5 to 6V), and a control connection. The GND connection is usually connected to a brown or black lead, the

FIGURE 6-30 Controlling a servo motor with pulses



positive connection to a red lead, and the control connection to an orange or yellow lead.

The control connection draws very little current. The server expects to receive a pulse every 20 ms or so. If the pulse is 1.5 ms in duration, then the servo will sit at its middle position. If the pulse is shorter, it will settle in a position to one side, and if the pulse is longer, it will move to a position on the other side of the center position.

You Will Need

To experiment with a servo and Arduino, you will need the following items.

Quantity	Item	Appendix Code
1	Arduino Uno/Leonardo	M2/M21
1	USB lead; Type B for Uno, Micro USB for Leonardo	
1	9g servo motor	H10
1	10kΩ variable resistor	K1, R1
	Jumper wires or solid-core wire	T6

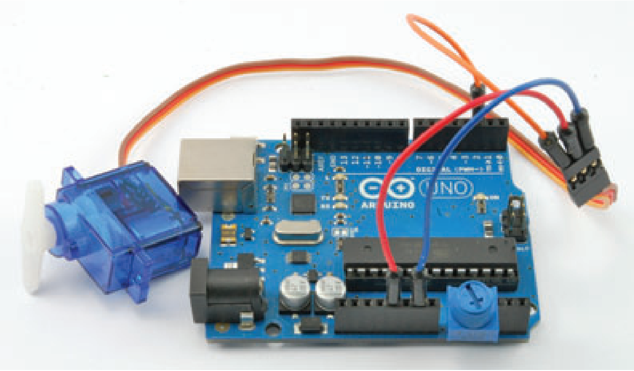
Construction

Figure 6-31 shows a servo connected to an Arduino using a jumper.

Before you power the servo motor from the 5V supply of an Arduino, first check that the Arduino can supply the current requirement. Most small servos will be just fine, such as the tiny 9g servo shown in Figure 6-31.

In Figure 6-31, you can also see the little blue trimpot used to set the position of the servo. This is connected to A1, but uses A0 and A2 to provide GND and +5V to the track ends of the variable resistor.

Figure 6-31 Connecting a servo to an Arduino



Software

The Arduino has a library specifically designed for generating the pulses that the servo needs. The following example sketch (called "servo") will use this library to set the position of the servo arm to follow the position of the knob on a variable resistor.

```
// servo

#include <Servo.h>

int gndPin = A0;
int plusPin = A2;
int potPin = 1;
int servoControlPin = 2;
```

After defining the pins to be used, the servo library requires the following line of code to set up the servo.

```
Servo servo;
```

The "setup" function sets up the pins and associates the "servo" with the "servoControlPin".

```
void setup()
{
  pinMode(gndPin, OUTPUT);
  digitalWrite(gndPin, LOW);
  pinMode(plusPin, OUTPUT);
  digitalWrite(plusPin, HIGH);
  servo.attach(servoControlPin);
}
```

The "loop" function continuously reads A1 to determine the position of the variable resistor (a number between 0 and 1023) and divides this number by 6 to convert it to an angle between 0 and 170. This is the angle in degrees to which the servo is then set.

```
void loop()
{
  int potPosition = analogRead(potPin);  // 0 to 1023
  int angle = potPosition / 6;           // 0 to 170
  servo.write(angle);
}
```

How to Charlieplex LEDs

An Arduino only has so many IO pins, so when looking to minimize the number of pins used to display a matrix of LEDs, an interesting technique called Charlieplexing can be used. The name comes from the inventor Charlie Allen at the company Maxim, and the technique takes advantage of the feature of Arduino and other microcontroller IO pins that allows them to be changed from outputs to inputs while a sketch is running.

Figure 6-32 shows the arrangement for controlling six LEDs with three pins.

Table 6-2 shows how the pins should be set to light a particular LED.

The number of LEDs that can be controlled per microcontroller pin is given by the following formula:

$$\text{LEDs} = n^2 - n$$

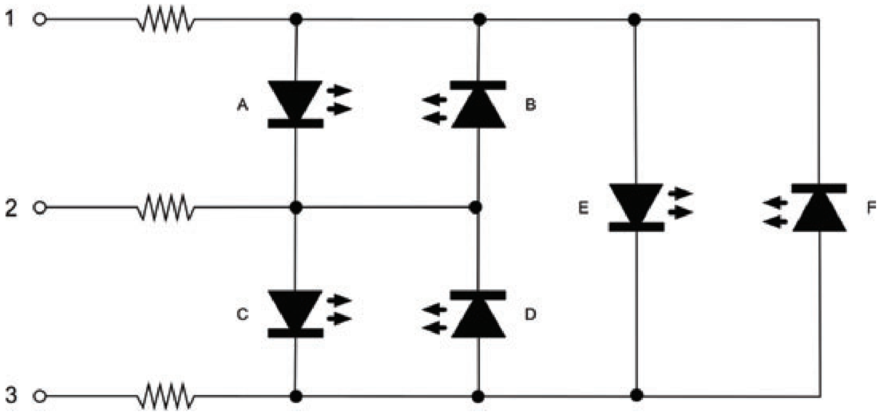
So, if we use four pins, we can have 16 – 4 or 12 LEDs, and 10 pins would give us a massive 90 LEDs, but an awful lot of wiring to do.

There are, however, problems with scaling Charlieplexing up, not the least of which is that the refresh rate needs to be fast enough to fool the eye, and a large number of pins will need a lot of sequence steps to energize all the LEDs that need energizing in a refresh cycle. This will also result in the LEDs becoming dim because their duty cycle will be low. You can compensate for this to some extent by increasing the current through the LEDs, which will cope with fairly large peak currents for a small duration. This does lead to the problem that

LED	Pin 1	Pin 2	Pin 3
A	High	Low	Input
B	Low	High	Input
C	Input	High	Low
D	Input	Low	High
E	High	Input	Low
F	Low	Input	High

TABLE 6-2 Charlieplexing

FIGURE 6-32 Charlieplexing LEDs



if the microcontroller freezes for some reason, then LEDs could burn out.

You Will Need

To Charlieplex six LEDs, you will need the following items.

Quantity	Item	Appendix Code
1	Arduino Uno/Leonardo	M2/M21
1	USB lead; Type B for Uno, Micro USB for Leonardo	
6	LEDs	S11
3	220Ω resistors	K2
	Jumper wires or solid-core wire	T6

Construction

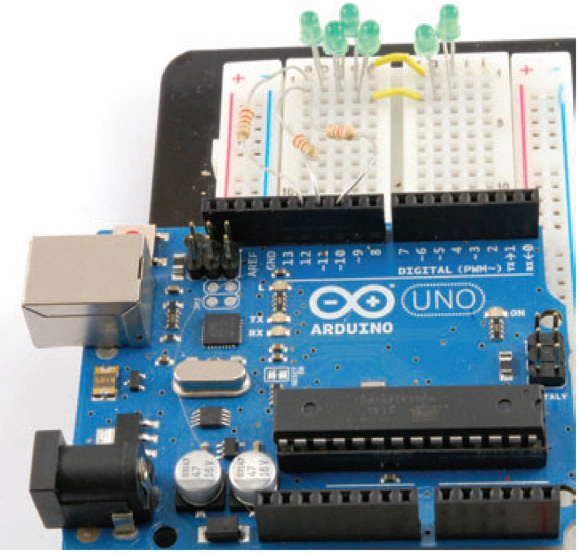
You will use breadboard to Charlieplex these LEDs (Figure 6-33).

The breadboard layout for this is shown in Figure 6-34. When constructing it, take special care to get the polarity of each LED correct.

The resistors are used to connect Arduino pins D12, D11, and D10 to the breadboard. The resistor leads will stay in the Arduino sockets better if you put a little zigzag kink in the leads using pliers.

The LEDs are very close together, so it is easier to make this with 3mm LEDs. The positive leads of the LEDs (anodes) are shown in red in Figure 6-34.

FIGURE 6-33 Six Charlieplexed LEDs on breadboard



Software

Load the sketch for this ("charlieplexing") onto your Arduino board, and you should see it cycle through the LEDs in the order A to F, as per Figure 6-32.

The sketch first defines three pins to be used as the control pins.

```
// charlieplexing

int pin1 = 12;
int pin2 = 11;
int pin3 = 10;
```

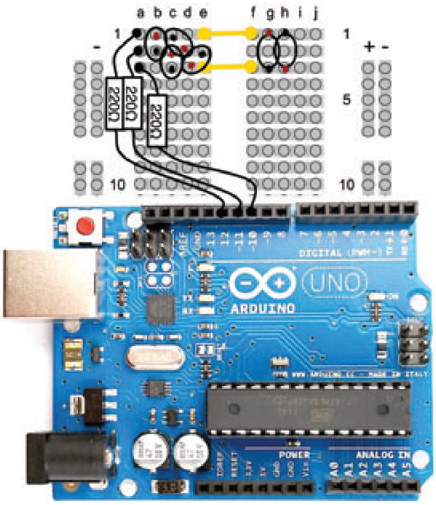


FIGURE 6-34 Breadboard layout for Charlieplexing

The pin states that we need to control each LED, as shown in Table 6-2, are contained in an array called "pinStates". Each element of this array is itself an array of three elements, one for each control pin. A value of 1 indicates that the control pin should be HIGH for that LED, 0 for a LOW, and –1 for an INPUT.

```
int pinStates[][3] = {
  {1, 0, -1}, // A
  {0, 1, -1}, // B
  {-1, 1, 0}, // C
  {-1, 0, 1}, // D
  {1, -1, 0}, // E
  {0, -1, 1}  // F
};
```

As we will be changing the pin mode of the control pins as we go, there is nothing to put in the "setup" function. You do, however, have to have the function there, even if it has nothing in it.

```
void setup()
{
}
```

The loop function steps through each of the LEDs and sets the control pin states according to the values in the appropriate row of the array, using the function "setPins".

```
void loop()
{
  for (int i = 0; i < 6; i++)
  {
    setPins(pinStates[i][0], pinStates[i][1], pinStates[i][2]);
    delay(1000);
  }
}
```

The function “setPins” does not do much except conveniently put the commands to set the state for each control pin into a single convenient line. Most of the logic lives in the “setPin” function that it calls.

```
void setPins(int p1, int p2, int p3)
{
  setPin(pin1, p1);
  setPin(pin2, p2);
  setPin(pin3, p3);
}
```

The “setPin” function sets the state of the pin supplied as its first argument. If the value of the state is –1, then the pin mode for the pin is set to INPUT. Otherwise, it is assumed to be a 1 or a 0 and the pin is set to be an OUTPUT and set to the value supplied with a call to “digitalWrite”.

```
void setPin(int pin, int value)
{
  if (value == -1)
  {
    pinMode(pin, INPUT);
  }
  else
  {
    pinMode(pin, OUTPUT);
    digitalWrite(pin, value);
  }
}
```

How to Type Passwords Automatically

The Arduino Leonardo can be used to impersonate a USB keyboard. Unfortunately, this is not true of the Arduino Uno, so in this section you will need an Arduino Leonardo.

Figure 6-35 shows the device we are going to construct.

All that happens when you press the button is that the Arduino Leonardo pretends to be a keyboard and types the password set in the sketch, wherever the cursor happens to be.

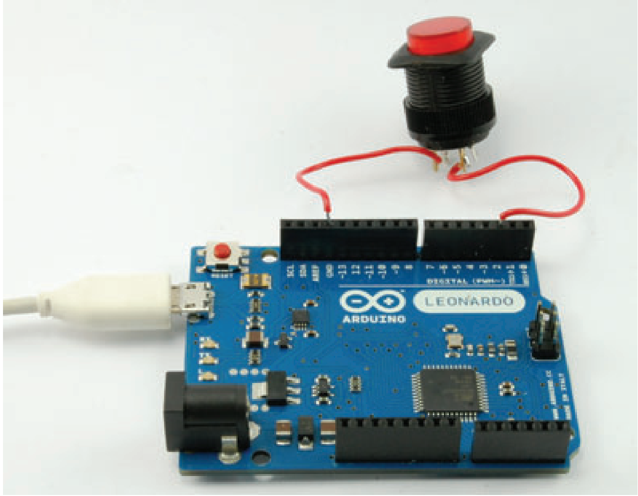

Figure 6-35 Entering passwords automatically with Arduino Leonardo

You Will Need

To build this, you will need the following items.

Quantity	Item	Appendix Code
1	Arduino Leonardo	M21
1	Micro USB lead for the Leonardo	
1	Impressive switch	H15
	Hookup wire	T7

Construction

Solder leads to the switch, and tin the ends so they can be pushed directly into the sockets on the Arduino. One lead from the switch should go to digital pin 2 and the other to GND.

Program the Arduino Leonardo with the sketch "password". Note that when programming the Leonardo, you may have to hold down the reset button until the message "uploading…" appears in the Arduino software.

Software

To use the project, just position your mouse over a password field and press the button. Please note that this project is really just to illustrate what you can do with an Arduino Leonardo. To find your password, all someone would have to do is press the button while in a word processor. So, in terms of security, it is about as secure as writing your password on a sticky note and attaching it to your computer monitor!

The sketch is very simple. The first step is to define a variable to contain your password. You will need to change this to your password. We then define the pin to use for the switch.

```
// password
// Arduino Leonardo Only

char* password = "mysecretpassword";

const int buttonPin = 2;
```

The Leonardo has access to special keyboard and mouse features not available to other types of Arduino. So, in the "setup" function, the Keyboard feature is started with the line "Keyboard.begin()".

```
void setup()
{
  pinMode(buttonPin, INPUT_PULLUP);
  Keyboard.begin();
}
```

In the main loop, the button is checked with a digital read. If the button is pressed, then the Leonardo uses "Keyboard.print" to send the password. It then waits two seconds to prevent the password being sent multiple times.

```
void loop()
{
  if (! digitalRead(buttonPin))
  {
    Keyboard.print(password);
    delay(2000);
  }
}
```

Summary

This chapter should have got you started using the Arduino and given you some food for thought for clever hacks using it. It has, however, only scratched the surface of what is possible with this versatile board.

For more information on programming the Arduino, you may wish to look at some of the author's other books on this topic. *Programming Arduino: Getting Started with Sketches* assumes no prior programming experience and will show you how to program the Arduino from first principals. *30 Arduino Projects for the Evil Genius* is a project-based book that explains both the hardware and programming side of Arduino, and is illustrated with example projects, nearly all of which are built on breadboard.

The official Arduino web site, www.arduino.cc, has a wealth of information on using the Arduino, as well as the official documentation for the Arduino commands and libraries.

7

Hacking with Modules

There are many modules available that provide a great shortcut when hacking together a project. These modules are usually a tiny PCB with a few components on them and some convenient connection points. They make it very easy to use some surface-mounted ICs that would otherwise be very difficult to solder connections to. Many of these modules are designed to be used with microcontrollers like the Arduino.

In this chapter, you will explore some of the more fun and useful modules available from suppliers like SparkFun and Adafruit, most of whose modules are also open-source hardware. So you'll get to see the schematics for them and even make your own modules using the design if you wish.

Access to the schematics and data sheets is very useful when trying to use a module. There are a few important things you need to know about any module before you use it:

- What is the range of supply voltage?
- How much current does it consume?
- How much current can any outputs supply?

How to Use a PIR Motion Sensor Module

PIR motion sensors are used in intruder alarms and for automatic security alarms. They detect movement using infrared light. They are also cheap and easy to use.

In this example, you will first experiment with a PIR module using it to light an LED, and then look at how it could be hooked up to an Arduino to send a warning message to the Serial Console.

You Will Need (PIR and LED)

Quantity	Names	Item	Appendix Code
1		PIR module (5–9V)	M5
1	D1	LED	K1
1	R1	470Ω resistor	K2
1		Solderless breadboard	T5
		Solid-core jumper wire	T6
1		4 × AA battery holder	H1
1		4 × AA batteries	
1		Battery clip	H2

Breadboard

Figure 7-1 shows the schematic diagram for this experiment.

Looking at the datasheet for this particular module, the supply voltage range is 5V to 7V, so it will work just fine with our four AA batteries.

The module is very easy to use. You just supply it with power and its output goes high (to supply voltage) when movement is detected and then back low again after a second or two.

The datasheet also says that the output can supply up to 10mA. That isn't a great deal, but is enough to light an LED. By choosing a 470Ω resistor, we will be limiting the current to:

I = V / R = (6V – 2V) / 470Ω = 4 / 470 = 8.5mA

Figure 7-2 shows the breadboard layout, while Figure 7-3 offers a photograph of the actual breadboard.

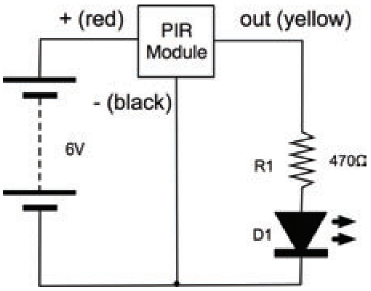

Figure 7-1 Schematic diagram—using a PIR module with an LED

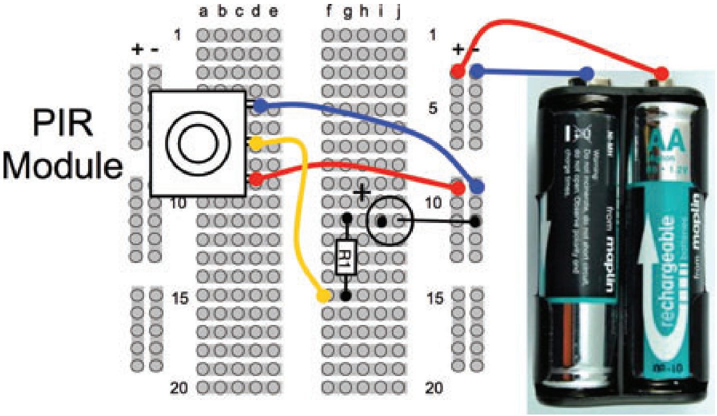

Figure 7-2 Breadboard layout—using a PIR module with an LED

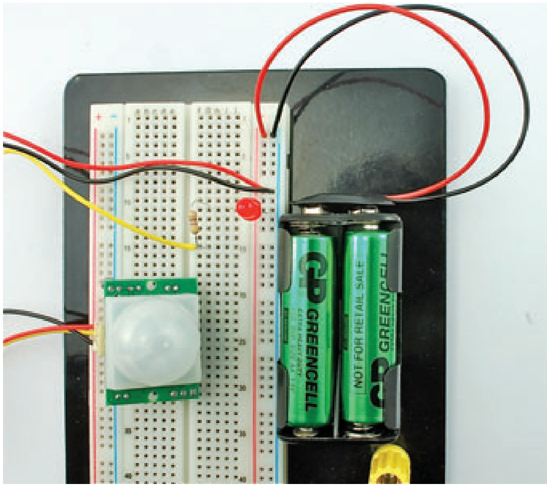

FIGURE 7-3 Using a PIR module with an LED

The PIR module has three pins labeled +5V, GND, and OUT. The supplied connector lead has red, black, and yellow leads. Hook it up so the red lead connects to the connection labeled +5V.

When it's powered up, the LED will light every time movement is detected.

Having already discussed the PIR sensor so we know what to expect of it, it's time to interface it with an Arduino.

You Will Need (PIR and Arduino)

To interface the PIR sensor with an Arduino, you really only need the PIR sensor and an Arduino.

Quantity	Item	Appendix Code
1	PIR module (5–9V)	M5
1	Arduino Uno/Leonardo	M2/M21
1	USB lead; Type B for Uno, Micro USB for Leonardo	

Construction

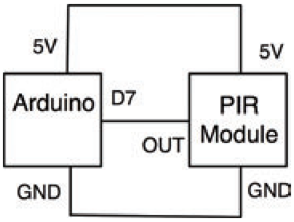

FIGURE 7-4 Schematic diagram for the Arduino and PIR sensor

Figure 7-4 shows the schematic diagram for this, while Figure 7-5 shows how the PIR module is wired to the module. To get the wires to stay in the Arduino sockets, it helps to put a little zigzag bend in the tinned end of the wire lead.

Before you move onto the next stage of programming the Arduino, temporarily remove the OUT lead from its Arduino socket. The reason for this is that you do not know what sketch was last running on the Arduino. It might have been something where pin 7 was an output, and if it was, this could easily damage the output electronics of the PIR sensor.

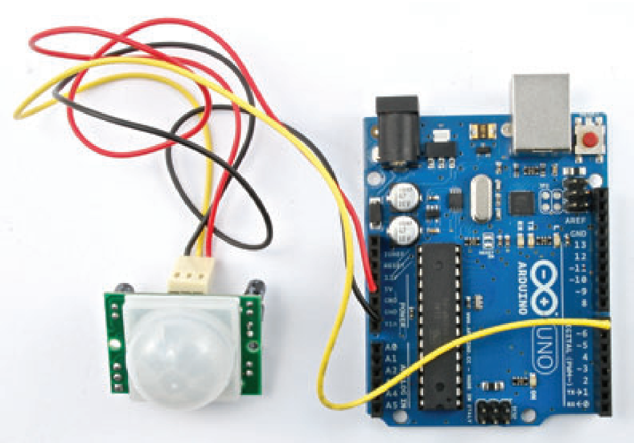

FIGURE 7-5 The Arduino and the PIR sensor

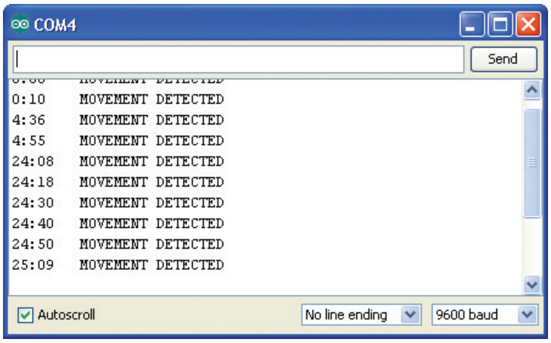
Software

Load the sketch "pir_warning" into the Arduino IDE and onto the Arduino board, and then plug the yellow "OUT" lead back into pin 7 on the Arduino.

When you launch the Serial Monitor (Figure 7-6), you will see an event appear every time movement is detected. Imagine leaving this running while away from your computer—to detect snoopers!

The sketch is very straightforward.



```
0:10     MOVEMENT DETECTED
4:36     MOVEMENT DETECTED
4:55     MOVEMENT DETECTED
24:08    MOVEMENT DETECTED
24:18    MOVEMENT DETECTED
24:30    MOVEMENT DETECTED
24:40    MOVEMENT DETECTED
24:50    MOVEMENT DETECTED
25:09    MOVEMENT DETECTED
```

FIGURE 7-6 The Serial Monitor showing intruder alerts

```
// pir_warning

int pirPin = 7;

void setup()
{
  pinMode(pirPin, INPUT);
  Serial.begin(9600);
}

void loop()
{
  if (digitalRead(pirPin))
  {
    int totalSeconds = millis() / 1000;
```

```
      int seconds = totalSeconds % 60;
      int mins = totalSeconds / 60;
      Serial.print(mins);
      Serial.print(":");
      if (seconds < 10) Serial.print("0");
      Serial.print(seconds);
      Serial.println("\tMOVEMENT DETECTED");
      delay(10000);
    }
}
```

The only part of the code that is a bit different than the other sketches we have seen deals with displaying an elapsed time in minutes and seconds next to each event.

This code uses the Arduino "millis" function, which returns the number of milliseconds since the Arduino was last reset. This is then separated into its minute and second components and the various parts printed out as a message. The last part to be displayed uses the "println" command that adds a line feed to the end of the text so the next text starts on a new line.

The special character "\t" in this "println" is a tab character, to line the output up neatly.

How to Use Ultrasonic Rangefinder Modules

Ultrasonic rangefinders use ultrasound (higher frequency than the human ear can hear) to measure the distance to a sound-reflective object. They measure the time it takes for a pulse of sound to travel to the object and back. Figure 7-7 shows two different types of sonar. On the left is a low-cost sonar module (less than USD 5) with separate ultrasonic transducers for

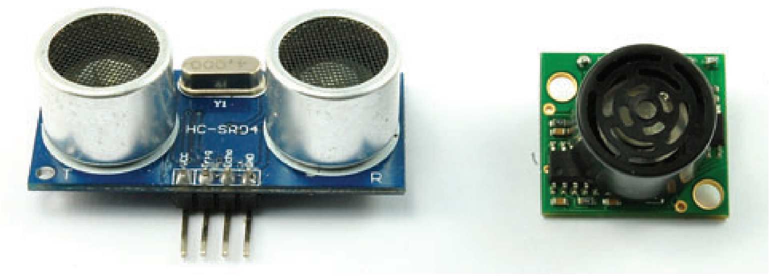


FIGURE 7-7 Ultrasonic rangefinders

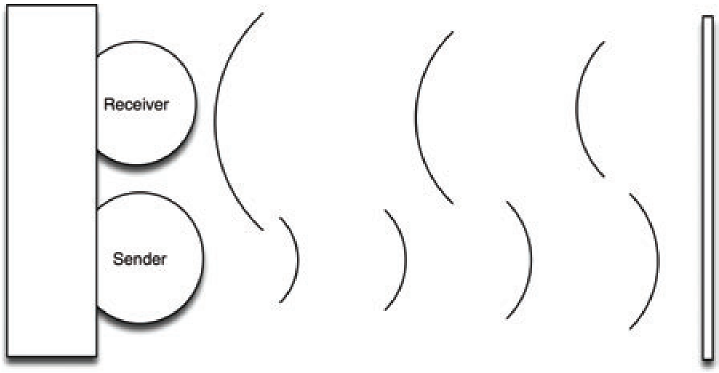

Figure 7-8 Ultrasonic range finding

sending the pulse and receiving the echo, and a much more expensive (around USD 25) but highly specified module made by MaxBotix Inc.

To see how to use these modules with an Arduino, we will try out each in turn.

Ultrasonic range finding works the same as sonar used by ships and submarines. A sound wave is sent out from a sender, hits an object, and bounces back. Since we know the speed of sound, the distance to the sound-reflecting object can be calculated from the time it takes for the sound to come back to the receiver (Figure 7-8).

The sound used is at a high frequency—hence, it is called ultrasonic. Most units operate at a frequency of about 40 kHz. Not many people can hear sounds above 20 kHz.

You Will Need

To try out both rangefinders, you will need the following items.

Quantity	Item	Appendix Code
1	Arduino Uno/Leonardo	M2/M21
1	USB Lead; Type B for Uno, Micro USB for Leonardo	
1	MaxBotix LV-EZ1 rangefinder	M6
1	HC-SR04 rangefinder	M7
1	Solderless breadboard	T5
	Solid-core jumper wire	T6

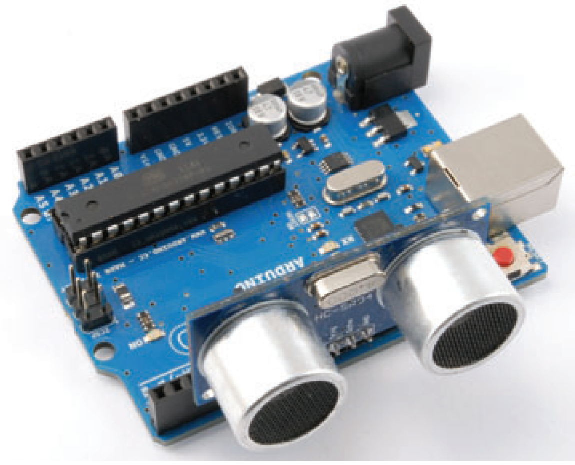

Figure 7-9 An HC-SR04 rangefinder on an Arduino

The HC-SR04 Rangefinder

These modules make the Arduino do a lot of the work, which is one reason why they are so much cheaper than the MaxBotix modules. They do, however, have the advantage that they can just fit into the side connector of an Arduino if you can spare the pins to supply them with current using two output pins (Figure 7-9).

Load the sketch "range_finder_budget" onto the Arduino and then plug the rangefinder module into the Arduino, as shown in Figure 7-9.

When you open the Serial Monitor, you will see a stream of distances in inches appear (Figure 7-10). Try pointing the rangefinder in different directions—say, a wall a few feet away—and confirm that the reading is reasonably accurate with a tape measure.

The Arduino code for measuring the range is all contained within the "takeSounding_cm" function. This sends a single 10-microsecond pulse to the "trigger" pin of the ultrasonic module, which then uses the built-in Arduino function "pulseIn" to measure the time period before the echo pin goes high.

9600 baud

Figure 7-10 Distance readings in the Serial Monitor

```
// range_finder_budget

int trigPin = 9;
int echoPin = 10;
int gndPin = 11;
int plusPin = 8;

int lastDistance = 0;

void setup()
{
  Serial.begin(9600);
  pinMode(trigPin, OUTPUT);
  pinMode(echoPin, INPUT);
  pinMode(gndPin, OUTPUT);
  digitalWrite(gndPin, LOW);
  pinMode(plusPin, OUTPUT);
  digitalWrite(plusPin, HIGH);
}
```

```
void loop()
{
  Serial.println(takeSounding_in());
  delay(500);
}

int takeSounding_cm()
{
  digitalWrite(trigPin, LOW);
  delayMicroseconds(2);
  digitalWrite(trigPin, HIGH);
  delayMicroseconds(10);
  digitalWrite(trigPin, LOW);
  delayMicroseconds(2);
  int duration = pulseIn(echoPin, HIGH);
  int distance = duration / 29 / 2;
  if (distance > 500)
  {
    return lastDistance;
  }
  else
  {
    lastDistance = distance;
    return distance;
  }
}

int takeSounding_in()
{
  return takeSounding_cm() * 2 / 5;
}
```

We then need to convert that time in milliseconds into a distance in centimeters. If there is no reflection because there is no object that is close enough, or the object is reflecting the sound wave away rather than letting it bounce back to the receiver, then the time of the pulse will be very large and so the distance will also be recorded as very large.

To filter out these long readings, we disregard any measurement that is greater than 5m, returning that last sensible reading we got.

The speed of sound is roughly 343 m/s in dry air at 20 degrees C, or 34,300 cm/s.

Or, put another way, 34,300 / 1,000,000 cm / microsecond.

That is, 0.0343 cm/microsecond.

Put another way, 1/0.0343 microseconds/cm.

Or, 29.15 microseconds/cm.

Thus, a time of 291.5 microseconds would indicate a distance of 10 cm.

The "takeSounding_cm" function approximates 29.15 to 29 and then also divides the answer by 2, as we don't want the distance of the whole return journey, just the distance to the subject.

In actual fact, many factors affect the speed of sound, so this approach will only ever give an approximate answer. The temperature and the humidity of the air will both affect the measurement.

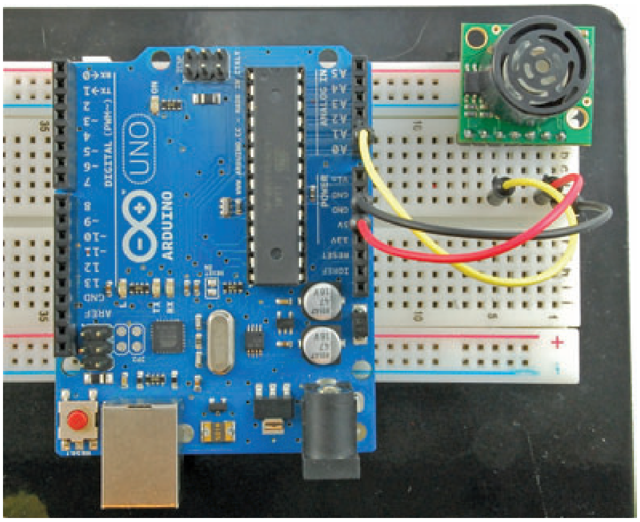
The MaxBotix LV-EZ1 Rangefinder

The HC-SR04 rangefinder only has a single type of interface, and we have to tell it to generate the sonar pulse, and then time how long it takes to come back ourselves.

In contrast, the MaxBotix device does all of this for us, and what's more it provides us with no less than three ways to get the distance readings:

- Serial data readings
- Analog (Vcc / 512) / inch
- Pulse width (147 µS/inch)

FIGURE 7-11 The MaxBotix rangefinder and Arduino



We will use the analog method to test out this device. The figure of Vcc / 512 per inch means that the analog output will be the supply voltage divided by 512 per inch. So if the object was 10 inches away, then the analog output voltage would be:

10 inches × 5V/ 512 = 0.098V

The MaxBotix module has too many pins to easily fit directly onto the Arduino connectors, so you will need to use breadboard.

Figure 7-11 shows the unit and the Arduino on the breadboard, while Figure 7-12 shows the breadboard layout.

Load up the sketch "range_finder_maxsonar" and then connect up the module as shown in Figure 7-11.

The sketch is much simpler than for the other module, and the distance in inches is just the raw analog reading (between 0 and 1023) divided by two.

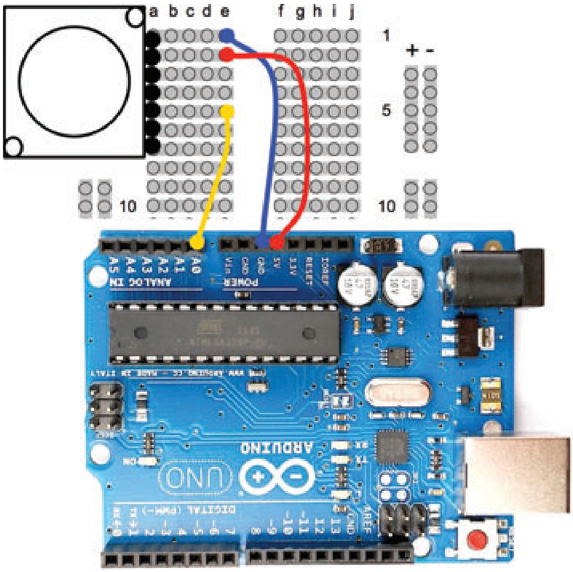


FIGURE 7-12 The MaxBotix rangefinder and Arduino breadboard layout

```
// range_finder_maxsonar

int readingPin = 0;

int lastDistance = 0;

void setup()
{
  Serial.begin(9600);
}

void loop()
{
  Serial.println(takeSounding_in());
  delay(500);
}

int takeSounding_in()
{
  int rawReading = analogRead(readingPin);
  return rawReading / 2;
}

int takeSounding_cm()
{
  return takeSounding_cm() * 5 / 2;
}
```

Opening the Serial Monitor will produce the same stream of distance measurements as the other module.

Note that both sketches have a metric and imperial distance measurement flavor for your convenience.

How to Use a Wireless Remote Module

Radio frequency circuits usually are not worth making yourself when extremely useful modules like the one shown in Figure 7-13 are readily available for just a few dollars.

The module shown can be easily found on eBay and has a handy little key-fob sized remote with four buttons on it. These buttons can toggle four digital pins on and off on the corresponding receiver module.

It is worth noting that modules like this are also available with relays instead of digital outputs, making it very easy to hack your own remote control projects.

You will first experiment with the module on breadboard, just turning on an LED, and then in the following section, you can try connecting it to an Arduino.

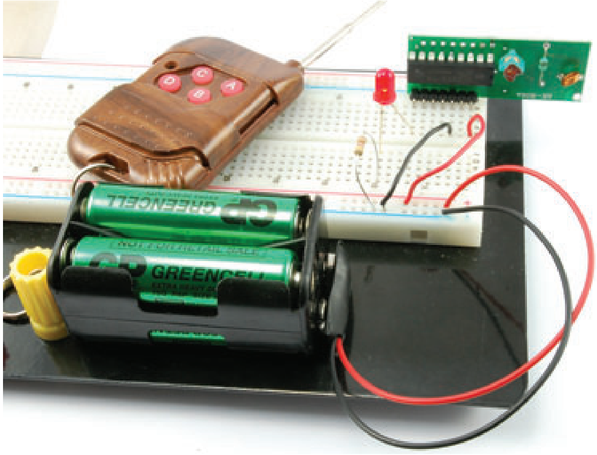

FIGURE 7-13 An RF module on breadboard

You Will Need

To try out the wireless remote on breadboard, you will need the following items.

Quantity	Names	Item	Appendix Code
1		Solderless breadboard	T5
		Solid-core jumper wire	T6
1		Wireless remote kit	M8
1	D1	LED	K1
1	R1	470Ω resistor	K2
1		4 ×AA battery holder	H1
1		Battery clip	H2
4		AA batteries	

Breadboard

Figure 7-14 shows the breadboard layout used to test the remote. You could, if you wished, add three more LEDs so there was one for each channel.

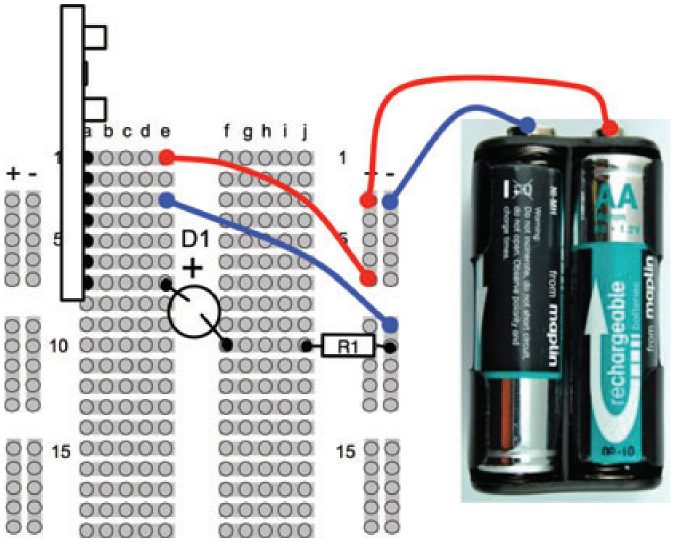

Figure 7-14 Breadboard layout for testing the RF module

The datasheet for this module shows that the pins are as shown in Table 7-1.

Put the module on the breadboard with pin 1 at the top of the breadboard, and wire it up as shown in Figure 7-14.

That really is all there is to it. Pressing button A should toggle the LED on and off. If you wanted to, you could add more LEDs so there was one for each channel, or try moving the LED to a different output to check that they all work.

Pin Number	Pin Name	Purpose
1	Vcc	Positive supply 4.5 to 7V
2	VT	Switch voltage—no connection needed
3	GND	Ground
4	D3	Digital output 3
5	D2	Digital output 2
6	D1	Digital output 1
7	D0	Digital output 0

TABLE 7-1 RF Receiver Pinout

How to Use a Wireless Remote Module with Arduino

If we are prepared to lose one of the four channels of the remote from the section "How to Use a Wireless Remote Module," then we can plug the receiver straight into the Arduino socket A0 to A5 (see Figure 7-15).

You Will Need

To try out the wireless remote with an Arduino, you will need the following items.

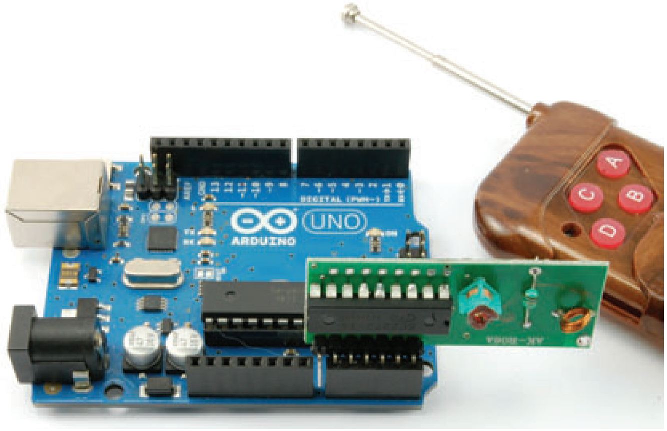
Quantity	Item	Appendix Code
1	Arduino Uno/Leonardo	M2/M21
1	USB lead; Type B for Uno, Micro USB for Leonardo	
1	Wireless Remote Kit	M8

Before plugging the remote receiver into the Arduino, upload the sketch "rf_remote".

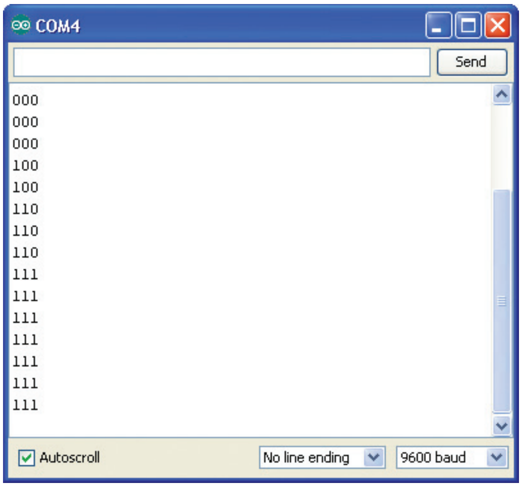
Software

With the software uploaded and the RF receiver attached, when you open the Serial Monitor you should see something like Figure 7-16.

Figure 7-15 Using a RF remote with an Arduino



The sketch displays as a 1 or 0 the current state of the remote control channels. So button A will not do anything (that is the button we sacrificed), but pressing the other buttons should toggle the appropriate column between 0 and 1.



```

```

☑ Autoscroll

No line ending

9600 baud

FIGURE 7-16 Remote control messages to your computer

```
// rf_remote

int gndPin = A3;
int plusPin = A5;
int bPin = A2;
int cPin = A1;
int dPin = A0;

void setup()
{
  pinMode(gndPin, OUTPUT);
  digitalWrite(gndPin, LOW);
  pinMode(plusPin, OUTPUT);
  digitalWrite(plusPin, HIGH);
  pinMode(bPin, INPUT);
  pinMode(cPin, INPUT);
  pinMode(dPin, INPUT);
  Serial.begin(9600);
}

void loop()
{
  Serial.print(digitalRead(bPin));
  Serial.print(digitalRead(cPin));
  Serial.println(digitalRead(dPin));
  delay(500);
}
```

The RF receiver uses very little current, so there is no problem powering it from a digital output. In fact, doing so has the added benefit that we can actually turn it off to save power simply by setting the “plusPin” low.

How to Control Motor Speed with a Power MOSFET

This section is a little out of place because MOSFET transistors are not modules. However, this section does lead in nicely to the next section on using motor controller modules.

We first used power MOSFETs in Chapter 3. They are a kind of transistor that is particularly suited to switching high-current loads efficiently. By efficiently, I mean that they run pretty cool, working very well as electronic switches. They have a very low "on" resistance and a very high "off resistance."

Back in Chapter 6, you used a technique called PWM (pulse-width modulation) to control the brightness of an LED by varying the length of pulses. You can use exactly the same trick on a DC motor. However, unlike an LED, motors use too much current to be driven directly from an Arduino output, so you will use a MOSFET controlled by the Arduino.

You Will Need

To build this, you will need the following items.

Quantity	Name	Item	Appendix Code
1		Solderless breadboard	T5
		Solid-core jumper wire	T6
1		4 × AA battery holder	H1
1		4 × AA batteries	
1		Battery clip	H2
1	R1	10kΩ trimpot	K1
1	R2	1kΩ resistor	K2
1	T1	FQP30N06 MOSFET	S6
1		6V DC motor or gear motor	H6
1		Arduino Uno/Leonardo	M2/M21
1		USB lead; Type B for Uno, Micro USB for Leonardo	

The DC motor can be any small motor you can find that is around 6V.

Breadboard

Figure 7-17 shows the schematic diagram.

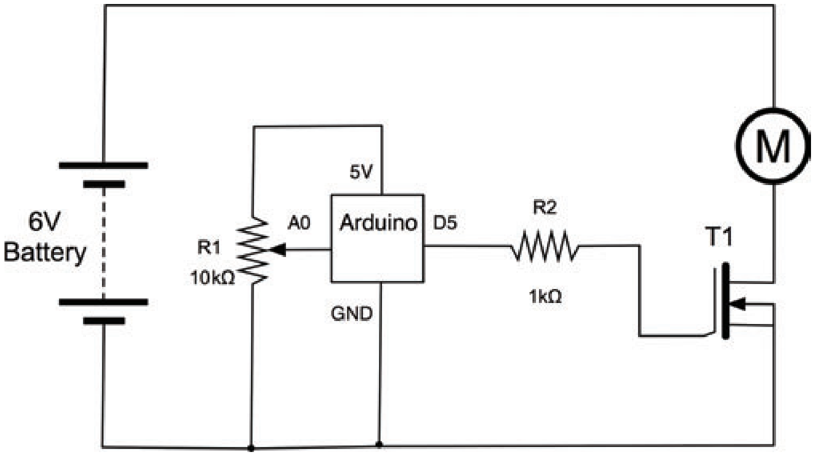
Notice that we actually have two sources of power here. We have the Arduino, which will be getting its power from your computer's USB port and a separate battery that supplied the power to the MOSFET. This is quite a common arrangement, because the Arduino's 5V output is not really suitable for high-current loads like a motor. Indeed, motors can create all sorts of problems for delicate electronics, so it is best not to power them from the Arduino.

There is less of a problem if the Arduino and motor share a power supply. For example, a 9V battery provides power to the Arduino through its power jack, and at the same time provides the positive supply to the motor.

I have included a resistor R2 between the Arduino output pin and the MOSFET. The circuit would work fine just connecting D5 directly to the gate; however, the gate acts like a capacitor, which means that when switched at very high speed it can actually cause quite a lot of current to flow from the digital output. This will not be a problem at the relatively slow PWM speeds used by the Arduino, but it is considered "good practice" to use a resistor here.

Figures 7-18 and 7-19 show the actual circuit and the breadboard layouts, respectively.

Figure 7-17 Schematic diagram for the MOSFET motor control



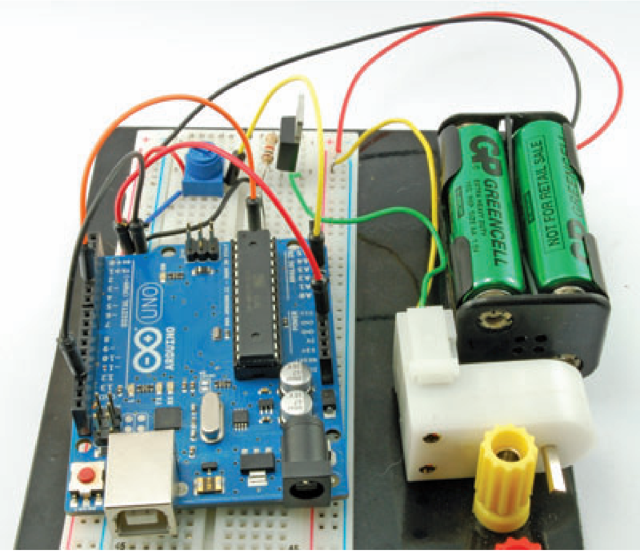


Figure 7-18 The MOSFET motor control

Software

Load the sketch "mosfet_motor_speed" onto the Arduino and connect the battery. You should find that by turning the variable resistor you have much finer control of the motor's speed than you did way back in Chapter 3 when you were just controlling the gate voltage of the MOSFET.

The sketch is very similar to the sketch we used to control the brightness of an LED from an Arduino in Chapter 6.

```
// mosfet_motor_speed
int voltsInPin = 0;
int motorPin = 5;

void setup()
{
  pinMode(motorPin, OUTPUT);
}

void loop()
{
  int rawReading = analogRead(voltsInPin);
  int power = rawReading / 4;
  analogWrite(motorPin, power);
}
```

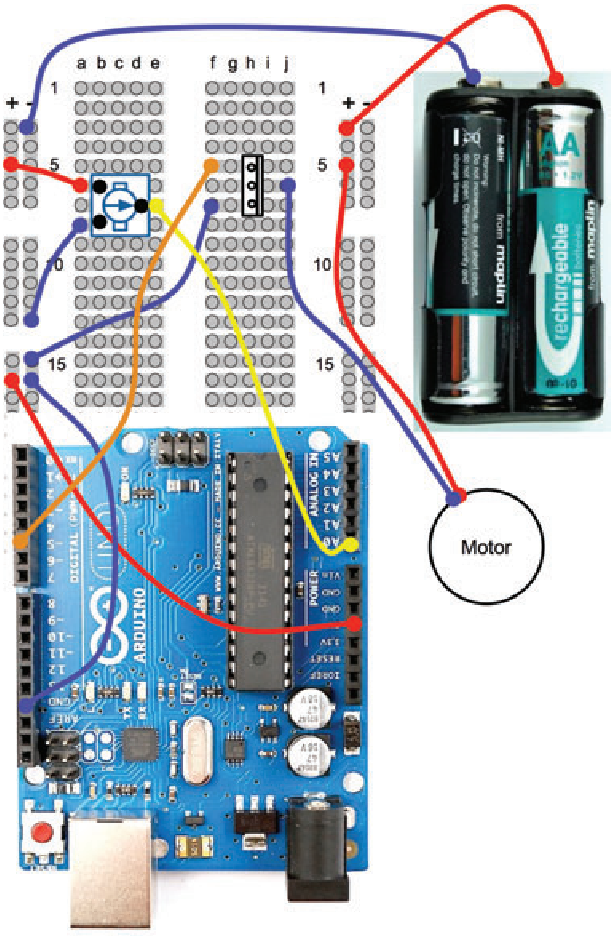

Figure 7-19 Breadboard layout for the MOSFET motor control

In the “loop” function, the raw reading of between 0 and 1023 from the analog input is divided by 4 to give us a number between 0 and 255 that is suitable for use with “analogWrite”.

How to Control DC Motors with an H-Bridge Module

In the earlier section of this chapter, “How to Control Motor Speed with a Power MOSFET,” we saw how you can use a MOSFET to control the speed of a motor. This is fine as long as you always want the motor to turn in the same direction. If you want to be able to reverse the direction of the motor, you need to use something called an H-Bridge.

To change the direction in which a motor turns, you have to reverse the direction in which the current flows. To do this requires four switches or transistors. Figure 7-20 shows how this works, using switches in an arrangement. You can now see why it is called an H-Bridge.

In Figure 7-20, S1 and S4 are closed, while S2 and S3 are open. This allows current to flow through the motor with terminal "A" positive and terminal "B" negative. If we were to reverse the switches so that S2 and S3 are closed and S1 and S4 are open, then "B" will be positive and "A" will be negative, and the motor will turn in the opposite direction.

You may, however, have spotted a danger with this circuit. That is, if by some chance S1 and S2 are both closed, then the positive supply will be directly connected to the negative supply and we will have a short circuit. The same is true if S3 and S4 are both closed at the same time.

You can build an H-Bridge yourself using transistors, and Figure 7-21 shows a typical H-Bridge schematic.

This schematic requires some six transistors and a good few other components. If you wanted to control two motors, you would need some 12 transistors, which causes everything to become quite complicated.

Fortunately, help is on hand as there are several H-Bridge ICs available that usually have two H-Bridges on a single chip and make controlling motors very easy. One such chip is

available as a module from SparkFun (Figure 7-22). You will find similar modules available from other module suppliers.

Figure 7-22 actually shows two of these modules so you can see both sides. The modules are supplied without connectors and the module on the left has pin headers soldered to it. This makes it very easy to use with breadboard.

Table 7-2 shows the pins of this module and explains the purpose of each. The module has two motor channels called A

and B and can drive motors with a current of 1.2A per channel with peak currents of over twice that.

We will experiment with this module using just one of its two H-Bridge channels (Figure 7-23).

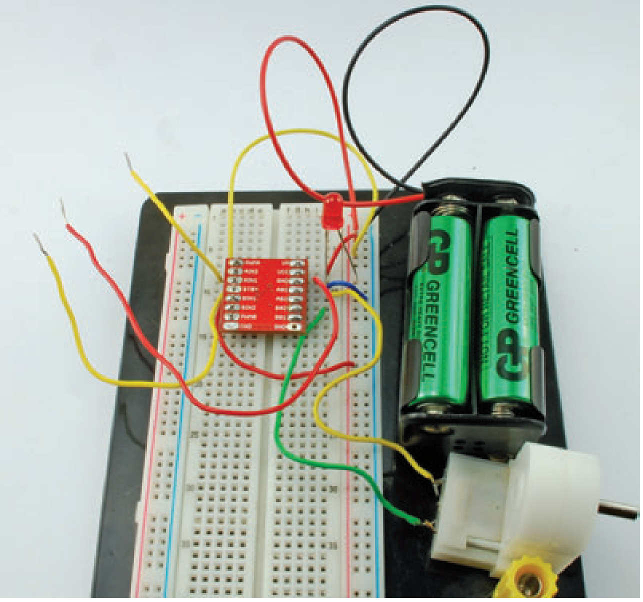

FIGURE 7-23 Experimenting with the SparkFun TB6612FNG breakout board

You Will Need

To build this, you will need the following items.

Quantity	Name	Item	Appendix Code
1		Solderless breadboard	T5
		Solid-core jumper wire	T6
1		4 × AA battery holder	H1
1		4 × AA batteries	
1		Battery clip	H2
1		LED	K1
1		SparkFun TB6612FNG Breakout Board	M9
1		6V DC motor or gear motor	H6
1		Header pins	K1, H4

The DC motor can be any small motor around 6V.

Breadboard

Before fitting the module onto the breadboard, you need to solder the header pins into place as shown in Figure 7-22. We won't use the bottom two GND connections, so you can just solder the top seven pins on each side.

Figure 7-24 shows the schematic diagram for the experiment, while Figure 7-25 displays the breadboard layout.

Figure 7-25 Breadboard layout for the H-Bridge experiment

The 6V battery pack is actually a slightly higher voltage than is (strictly speaking) allowed for VCC on the module. You would probably get away with the extra half volt above the nominal maximum voltage of 5.5V, but to play it safe, we can use an LED to drop 2V, so that VCC will be around 4V, which is well within its range.

This is a useful trick, but only use it when the current flowing is less than the maximum forward current of the LED. In fact, in this experiment, the current required for VCC is not even enough to make the LED glow.

The PWMA pin is connected to VCC, which simulates the PWN control signal being on all the time—in other words, there is full power to the motor.

Next, put everything on the breadboard as shown in Figure 7-25.

Using the Control Pins

Three of the leads from the breadboard do not actually go anywhere. You will control the motor, touching the red lead going to VCC to AIN1, and then to AIN2, in turn. Note how the motor turns first in one direction and then the other.

You might be wondering why there are two control pins, as well as the PWM pin for each motor channel. In theory, you could have one direction pin and one PWM pin, and if the PWM power was zero, then the motor would not turn at all.

The reason we have three pins to control each motor (PWM, IN1, and IN2) rather than just two is that if both IN1 and IN2 are high (connected to VCC), then the H-Bridge operates in a "braking" mode, which provides electrical braking of the motor, slowing it down. This feature is not often used, but can be useful if you want to stop the motor quickly.

How to Control a Stepper Motor with an H-Bridge Module

Normal DC motors are nice and easy to use. There are just two connections to make and if the voltage is applied one way it turns clockwise; reverse the polarity and it turns counterclockwise. The down side to normal DC motors is that if you want to know what position it has turned to, you have to use some kind of sensor.

Stepper motors are entirely different kinds of motors. They commonly have four connections. Figure 7-26 shows how a stepper motor works. Or more specifically, a bipolar stepper motor, which is the one we will try out.

The motor contains a toothed rotor where each of the teeth of the rotor are magnets, of alternating north and south poles.

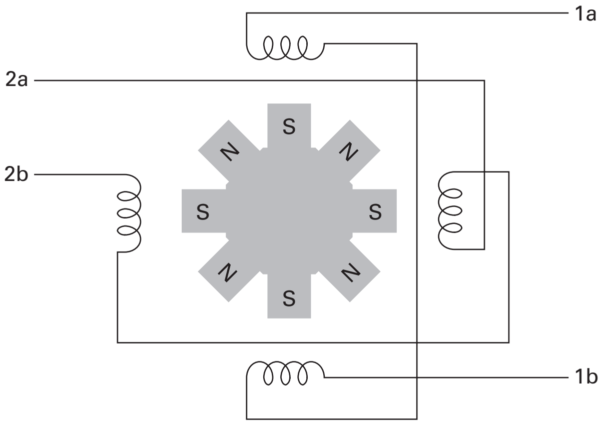

FIGURE 7-26 How a bipolar stepper motor works

Four coils, acting as electromagnets will, when energized in the right order, move the rotor around one step. The coils are arranged in pairs, wired so that as one pushes, its opposite number pulls.

Most stepper motors will have far more steps than the eight shown in Figure 7-26, sometimes 200 or more. This makes the motors very flexible, because they can run freely just like any other motor, by sending the stepping pulses quickly, or they can be controlled very precisely by just moving them forward one step at a time. For this reason, you will find stepper motors in inkjet printers and also 3D printers.

Because the stepper motor will only turn, if we generate a series of pulses in the right order, and need to be able to reverse the direction of current flow in the coils, we can use an Arduino to generate the control signals and an H-Bridge module to supply the power to the coils (Figure 7-27).

Figure 7-28 shows the schematic diagram for this arrangement.

Identifying which lead is which on a stepper motor sometimes requires a bit of trial and error. Using a multimeter, you can measure the resistance between pairs of leads and therefore work out which leads are connected to the same coil.

Another way of finding the leads that belong to the same coil is to hold two of the leads together and see if it makes the shaft of the motor more difficult to turn. Strange, but true!

FIGURE 7-28 Schematic diagram for a stepper motor control

If when you turn it on, the motor doesn't turn, you will only need to swap over one of the coil's leads. The colors indicated in Figure 7-28 match the lead colors for the Adafruit motor.

Although the motors suggested are 12V, they will still work using the 6V supplied by the battery pack. However, do not try and power them from the 5V supply of the Arduino. They draw too much current.

You Will Need

To build this, you will need the following items.

FIGURE 7-29 Breadboard layout for the stepper motor

Software

The example sketch ("stepper") will first of all turn the motor in one direction through 200 steps and then pause for a second before turning it in the opposite direction through 200 steps. For a 200-step motor, each turn will be a full 360 degrees.

First, the pin variables are defined and the "setup" function sets them all to be outputs.

```
// stepper

int PWMApin = 9;
int AIN1pin = 7;
int AIN2pin = 8;
int PWMBpin = 3;
int BIN1pin = 5;
int BIN2pin = 4;

void setup()
{
  pinMode(PWMApin, OUTPUT);
  pinMode(AIN1pin, OUTPUT);
  pinMode(AIN2pin, OUTPUT);
  pinMode(PWMBpin, OUTPUT);
  pinMode(BIN1pin, OUTPUT);
  pinMode(BIN2pin, OUTPUT);
}
```

The "loop" function then directs the motor in one direction (forward) for 200 steps, pauses a second, and then directs the motor back the same number of steps, but with half the delay between steps before pausing another second. It will continue this indefinitely.

```
void loop()
{
  forward(10, 200);
  delay(1000);
  back(5, 200);
  delay(1000);
}
```

The functions "forward" and "back" both take two parameters. The first is the delay between each step in milliseconds, and the second is the number of steps to take.

The "forward" and "back" functions use the function "setStep" to set the right polarities of the two coils, in the pattern 1010, 0110, 0101, 1001.

```
void forward(int d, int steps)
{
  for (int i = 0; i < steps / 4; i++)
  {
    setStep(1, 0, 1, 0);
    delay(d);
    setStep(0, 1, 1, 0);
    delay(d);
    setStep(0, 1, 0, 1);
    delay(d);
    setStep(1, 0, 0, 1);
    delay(d);
  }
}
```

To make the motor turn in the opposite direction, the pattern is just reversed.

```
void back(int d, int steps)
{
  for (int i = 0; i < steps / 4; i++)
  {
    setStep(1, 0, 0, 1);
    delay(d);
    setStep(0, 1, 0, 1);
    delay(d);
    setStep(0, 1, 1, 0);
    delay(d);
    setStep(1, 0, 1, 0);
    delay(d);
  }
}
```

The “setStep” function actually sets the appropriate outputs of the motor controller.

```
void setStep(int w1, int w2, int w3, int w4)
{
  digitalWrite(AIN1pin, w1);
  digitalWrite(AIN2pin, w2);
  digitalWrite(PWMApin, 1);
  digitalWrite(BIN1pin, w3);
  digitalWrite(BIN2pin, w4);
  digitalWrite(PWMBpin, 1);
}
```

How to Make a Simple Robot Rover

In this project, we will create a little roving robot. To do this, we will use the RF remote control we used in the section “How to Use a Wireless Remote Module,” with the H-Bridge module we

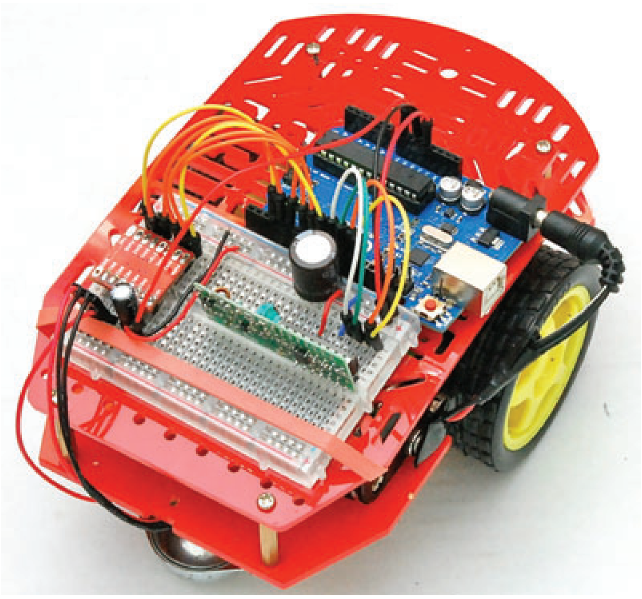

Figure 7-30 The robot rover

just discussed in the section "How to Control DC Motors with an H-Bridge Module," along with an Arduino.

The project will demonstrate how to use an Arduino to control a motor module.

The robot (Figure 7-30) will be built using a low-cost robot chassis kit that includes two gear motors.

The robot is built using a small breadboard that holds both the motor module and the RF receiver module. So apart from putting pin headers on the motor controller, there is no soldering to be done in this project.

You Will Need

To build this, you will need the following items.

Quantity	Name	Item	Appendix Code
1		Small solderless breadboard	H12
		Solid-core jumper wire	T6
1		6 × AA battery holder	H8
1		6 × AA batteries	
*1		Battery clip to 2.1mm DC jack adapter	H9

Quantity	Name	Item	Appendix Code
1		LED	K1
1		SparkFun TB6612FNG breakout board	M9
1		Magician chassis	H7
1		Header pins	K1, H4
1	C1	1000µF 16V capacitor	C1
1	C2	100µF 16V capacitor	C2
1		Arduino Uno/Leonardo	M2/M21
1		USB lead; Type B for Uno, Micro USB for Leonardo	

* If you use the Adafruit battery box that is already terminated in a 2.1mm plug, then you do not need this.

Construction

Figure 7-31 shows the schematic diagram for the rover.

The use of modules simplifies this greatly. The only additional components that have been added are the two capacitors: C1 and C2. These are necessary to prevent sudden drops in battery voltage (as the motors start) from causing the Arduino to reset.

Step 1. Construct the Magician Chassis

The project is built around the Magician Chassis (Figure 7-32). This comes as a kit that is fixed together with nuts and bolts. Follow the instructions that come with the Chassis, but do not attach the battery box that comes with the kit or the support pillar that is right in the middle of the board. This is because, to power the Arduino, you need a bit more than the 5V to 6V that four AAs can supply. So, you are going to replace the battery box with one that takes six AA batteries rather than just four.

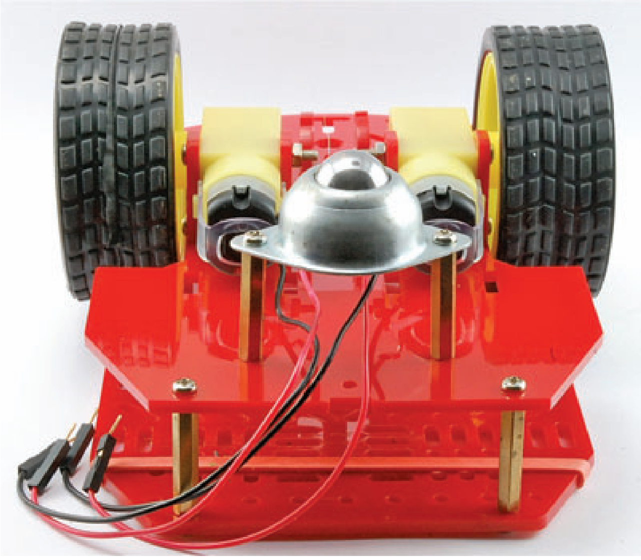

Figure 7-32 The Magician Chassis

Step 2. Program the Arduino

It is a good idea to program the Arduino with the sketch before you start attaching the electronics. Load the sketch "rover" onto the Arduino.

Step 3. Attach the Arduino and Breadboard

Find suitable mounting holes on the chassis and use small nuts and bolts to attach the Arduino. You can also use an elastic band for this. Some breadboards come with a self-adhesive backing, and you can use this to attach it to the chassis. For a less permanent way of attaching it, a rubber band will work just fine.

Step 4. Build the Breadboard

Figure 7-33 shows the breadboard layout for the project and how it is wired up to the Arduino.

There are quite a lot of wires on this project, so check all the connections once you think you have finished. Photocopying the page of the book and checking off with a pencil each connection as it's made is a good way of ensuring they are all there.

Also, not unlike our normal large breadboard, when wiring up this breadboard we have used the outer supply rail as GND and the inner rail as 5V.

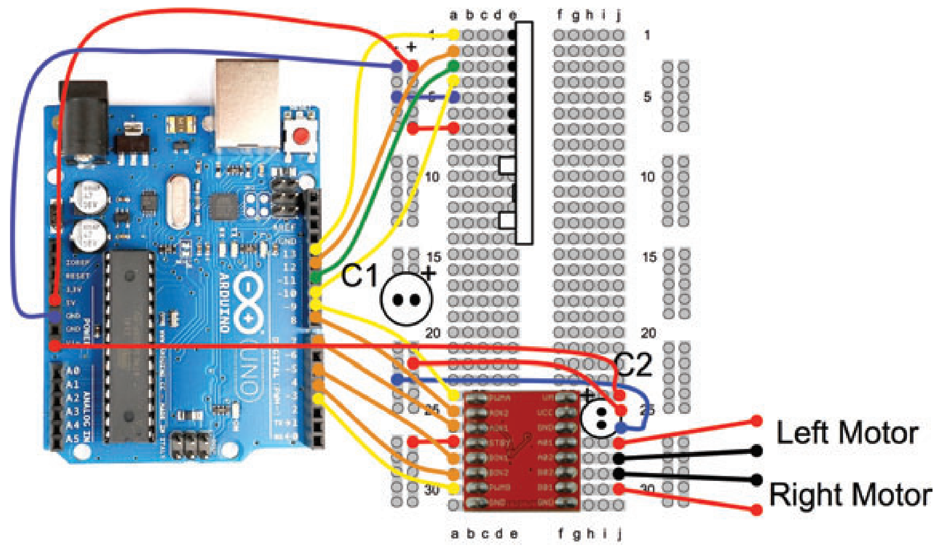

FIGURE 7-33 Breadboard layout for the rover

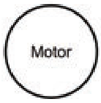

Step 5. Wire up the Motors

Each motor has a red and a black lead. So find the leads going to the left motor and attach them to the breadboard rows connected to the A01 and A02 connections of the motor module. Then, do the same for the right motor, connecting them to B01 and B02.

Step 6. Attach the Battery

If the battery box is made up of two rows of batteries, it will be quite a snug fit and the top surface of the chassis will need to bend out a little to accommodate it. If it is all in one row, like the Adafruit box, then you can attach it to the bottom layer of the chassis using small nuts and bolts.

Testing

When everything is assembled and ready to go, attach the battery and try the project out by pressing the buttons on the remote. The C button will set the robot running forwards, the B button will make it rotate to the right on the spot, and D will make it turn to the left. The A button will bring the robot to a halt.

Software

The sketch for this project is too long to list in full here, so we will just look at some of the main points.

The RF receiver toggles the output for the button you press. So press it once and it turns on, press it again and it turns off. However, this is not really the way we want it to work. We just want to know when a button has been pressed.

To do that, we keep track of the last state of each of the outputs, and only when the output has changed do we report the change. This uses the following array to store the output states and another array "remotePins":

```
int remotePins[] = {10, 11, 12, 13};
int lastPinStates[] = {0, 0, 0, 0};
```

The function that detects that a change has occurred is as follows:

```
int getKeyPress()
{
  // the outputs on the RF module toggle
  // so see what's changed and that's the
  // key that was pressed
  int result = -1;
  for (int i = 0; i < 4; i++)
  {
    int remoteInput = digitalRead(remotePins[i]);
    //Serial.print(remoteInput);
    if (remoteInput != lastPinStates[i])
    {
      result = i;
    }
    lastPinStates[i] = remoteInput;
  }
  return result;
}
```

The main loop calls this function to detect any key presses and then calls the appropriate function for the button.

```
void loop()
{
   int keyPressed = getKeyPress();
   Serial.println(keyPressed);
   if (keyPressed == 3)
   {
     stopMotors();
   }
   else if (keyPressed == 0)
   {
     turnLeft();
   }
   else if (keyPressed == 2)
   {
     turnRight();
   }
   else if (keyPressed == 1)
   {
     forward();
   }
   delay(20);
}
```

The functions that control the movement are all very similar. The function for turning left is shown next.

```
void turnLeft()
{
  digitalWrite(AIN1pin, HIGH);
  digitalWrite(AIN2pin, LOW);
  analogWrite(PWMApin, slowPower);
  digitalWrite(BIN1pin, LOW);
  digitalWrite(BIN2pin, HIGH);
  analogWrite(PWMBpin, slowPower);
}
```

This sets the AIN and BIN pins—in this case, to set the motors turning in opposite directions. The PWM power is controlled by a call to "analogWrite" using one of two values held in variables ("fullPower" and "slowPower").

How to Use a Seven-Segment LED Display Module

Seven-segment LED displays have a nice retro feel to them.

LED displays made up of a number of LEDs contained in a single package can be a challenge to control. Such displays will normally be controlled using a microcontroller; however, it is not necessary to use a microcontroller output pin to each individual LED. But rather, multi-LED displays are organized as "common anode" or "common cathode," with all the LED terminals of the anode or cathode connected together and then brought out through one pin. Figure 7-34 shows how a common cathode seven-segment display might be wired internally.

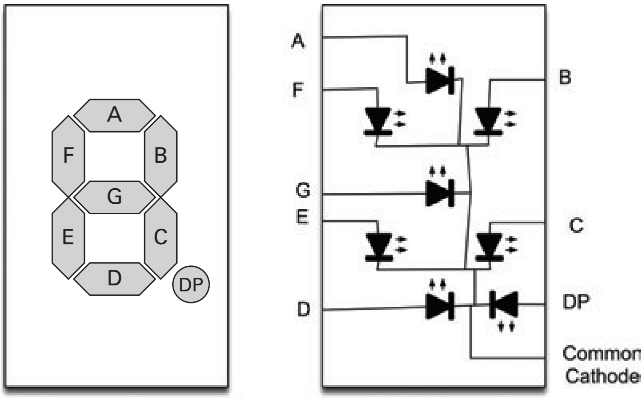

Figure 7-34 A common cathode LED display

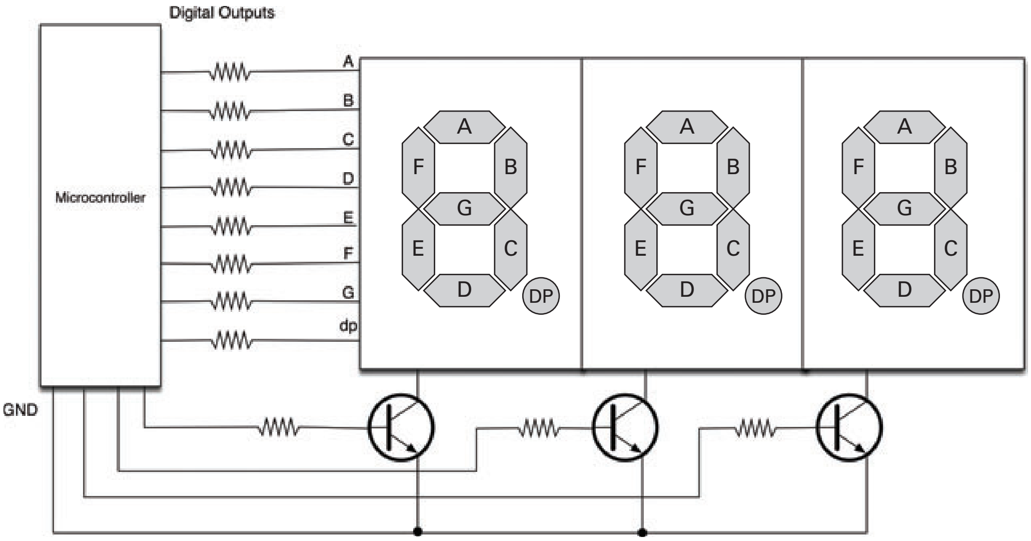
In a common cathode display like this, the common cathode would be connected to ground and each segment anode driven by a microcontroller pin through a separate resistor. Do not be tempted to use one resistor on the common pin, and don't use any resistors on the non-common connections, since the current will be limited no matter how many LEDs are lit. Because of this, the display will get dimmer the more LEDs are illuminated.

It is quite common for multiple displays to be contained in the same case—for example, the three-digit, seven-segment common cathode LED display shown in Figure 7-35.

In this kind of display, each digit of the display is like the single-digit display of Figure 7-35, and has its own common cathode. In addition, all the A segment anodes are connected together, as are each segment.

Figure 7-35 A three-digit, seven-segment LED display



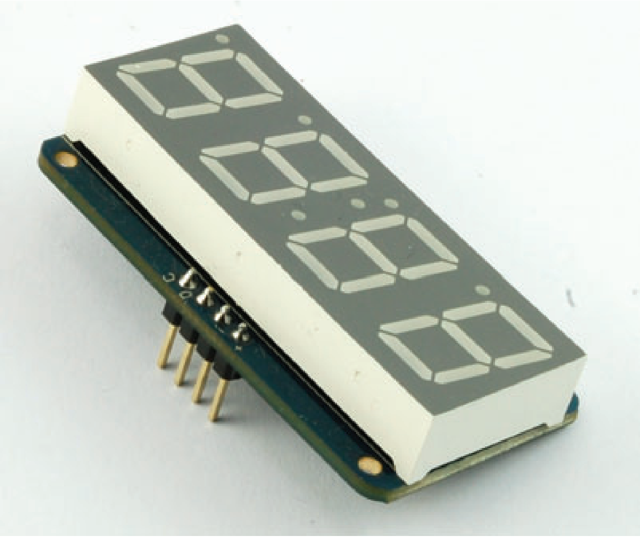


FIGURE 7-36 A four-digit, seven-segment I2C display

The Arduino using the display will then activate each common cathode in turn and then turn on the appropriate segments for that digit, and then move onto the next digit, and so on. This refresh happens very quickly so that the display appears to display different numbers on each digit. This is called multiplexing.

Note the use of transistors to control the common cathodes. This is simply to handle the current of potentially eight LEDs at once, which would be too much for most microcontrollers.

Fortunately for us, there is a much simpler way to use multi-digit, seven-segment LED displays. Modules ride to the rescue once again!

Figure 7-36 shows a four-digit, seven-segment LED display that has just four pins on its connector, and two of them are for power.

You Will Need

To build this, you will need the following items.

Quantity	Item	Appendix Code
1	Solderless breadboard	T5
	Solid-core jumper wire	T6
1	Arduino Uno/Leonardo	M2/M21
1	USB lead; Type B for Uno, Micro USB for Leonardo	
1	Adafruit seven-segment display w/I2C backpack	M19

Construction

The module comes as a kit, so start by following the instructions that accompany the module to assemble it.

The LED module uses a type of serial interface on the Arduino called I2C (pronounced "I squared C"). This requires just two pins, but they have to be the two pins above "AREF" on the Arduino Uno. These pins are named SDA and SCL.

This means that, frustratingly, the module will not just plug straight into the Arduino, we will need to use breadboard.

Figure 7-37 shows the breadboard layout and Figure 7-38 the breadboard itself, with the seven-segment display in action.

FIGURE 7-37 Breadboard layout for using the seven-segment display

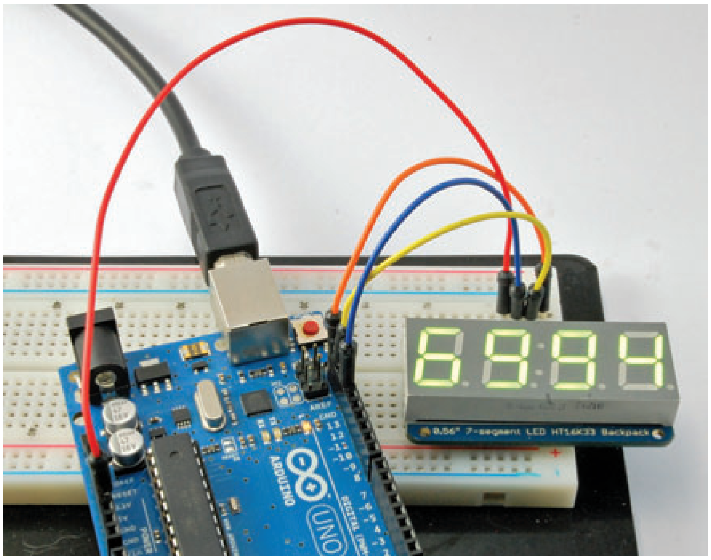

Figure 7-38 The seven-segment display in action

Software

Adafruit provides a library to simplify the use of the module. You need to download this and copy the library folder into the "libraries" folder in your Arduino documents folder. See the instructions on Adafruit's web site at www.adafruit.com/products/880.

The three libraries that the module requires are loaded using the #includes statements.

```
// seven_seg_display

#include <Wire.h>
#include "Adafruit_LEDBackpack.h"
#include "Adafruit_GFX.h"
```

The following line assigns a variable to the display object so we can tell it what to display.

```
Adafruit_7segment disp = Adafruit_7segment();
```

The "setup" function begins serial communication on the I2C pins and then initializes the display. The value 0x70 is the I2C address of the display module. This is the default value for its address, but there are solder connections on the module you can short together to change the address. You might want to do this if you need to use more than one display, since each display must have a different address.

```
void setup()
{
  Wire.begin();
  disp.begin(0x70);
}
```

The “loop” function simply displays the current number of milliseconds since the board was reset, divided by 10. The display will therefore count up in 1/100ths of a second.

```
void loop()
{
  disp.print(millis() / 10);
  disp.writeDisplay();
  delay(10);
}
```

How to Use a Real-Time Clock Module

You could write an Arduino sketch to keep track of the time, but as soon as you unplugged it, it would forget the time. The way around this problem is to use an RTC (real-time clock) like the one shown in Figure 7-39.

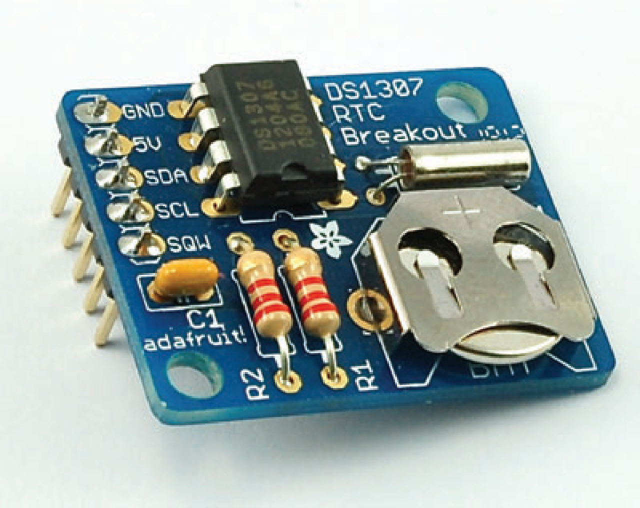

Figure 7-39 An RTC module

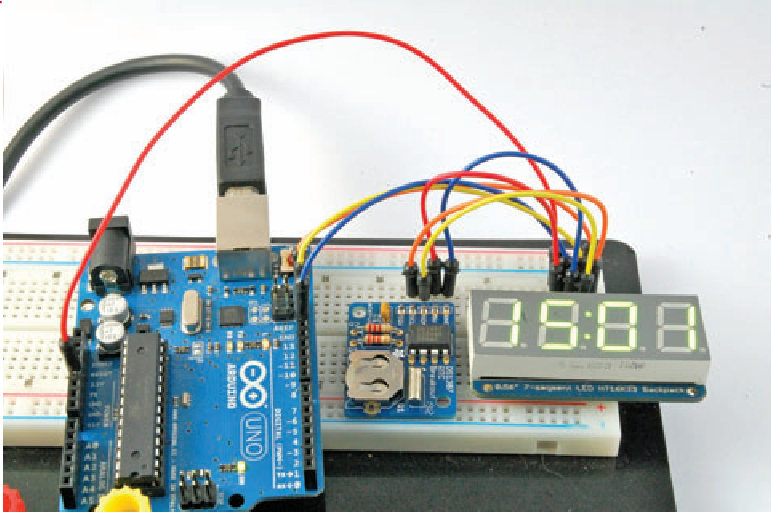
FIGURE 7-40 A "simple" digital clock



This particular module is also an Adafruit product. There are lots of similar modules out there, but their pin allocations may be different.

The RTC includes a lithium battery that will last for years, and provides enough power to keep the correct time when the module is not powered.

We can combine the RTC module with the seven-segment display module we used previously and make ourselves a simple digital clock (Figure 7-40).

You Will Need

To build this, you will need the following items.

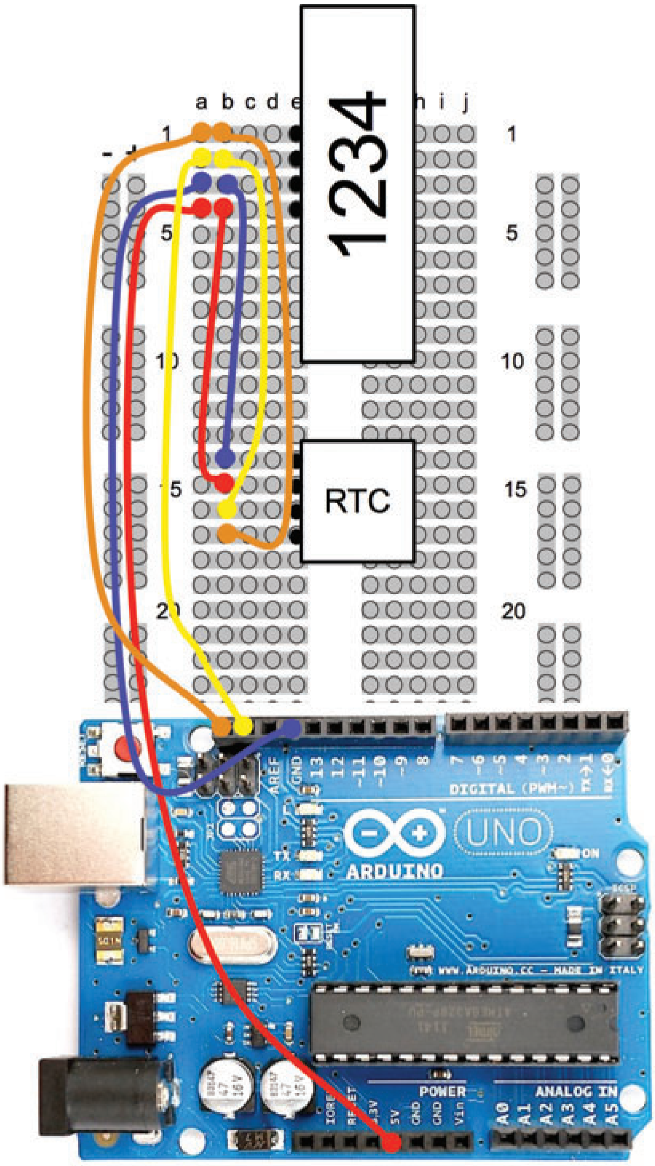
Quantity	Item	Appendix Code
1	Solderless breadboard	T5
	Solid-core jumper wire	T6
1	Arduino Uno/Leonardo	M2/M21
1	USB lead; Type B for Uno, Micro USB for Leonardo	
1	Adafruit seven-segment display w/I2C backpack	M19
1	RTC module	

Construction

The RTC module also comes as a kit, so start by following the instructions that accompany the module to assemble it.

The RTC module also uses I2C and has a different address to the display, so we do not need to change anything.

Figure 7-41 shows the breadboard layout for the clock.



a b c d e
h i j

5
10
15
20
1234
RTC
ARDUINO
UNO
DIGITAL (PWM~)
POWER
ANALOG IN

FIGURE 7-41 Breadboard layout for the clock

Software

Load up the sketch "clock" onto your Arduino. The display should immediately start showing the time your computer is set to.

Much of this sketch is the same as that in the section "How to Use a Seven-Segment LED Display Module." But there is one additional library for the RTC module that we need to import. Instructions for downloading this are linked from the product page for the RTC module (www.adafruit.com/products/264).

```
// clock

#include <Wire.h>
#include "Adafruit_LEDBackpack.h"
#include "Adafruit_GFX.h"
#include "RTClib.h"
```

In addition to creating a display to use, we now have to give the RTC a name. Let's call it "RTC".

```
RTC_DS1307 RTC;
Adafruit_7segment disp = Adafruit_7segment();
```

The "setup" function now has an additional command to start the RTC so it is ready to receive commands. The "if" statement checks to see if the clock part of the RTC is active. If this is the first time it has been used, it will not be, so if this is the case, it initializes it to the programming computer's time.

```
void setup()
{
  Wire.begin();
  RTC.begin();
  if (! RTC.isrunning())
  {
    RTC.adjust(DateTime(__DATE__, __TIME__));
  }
  disp.begin(0x70);
}
```

The main loop now reads the time from the RTC and displays it. It also uses the display libraries' "drawColon" function to make the colon flash by turning it on and off with a half-second delay in between.

```
void loop()
{
  disp.print(getDecimalTime());
  disp.drawColon(true);
  disp.writeDisplay();
  delay(500);
  disp.drawColon(false);
  disp.writeDisplay();
  delay(500);
}
```

The “getDecimalTime” function reads the hours and minutes from the RTC and turns them into a decimal number that can be written to the display. The first two digits will contain the hour, and the left two digits the minute.

```
int getDecimalTime()
{
  DateTime now = RTC.now();
  int decimalTime = now.hour() * 100 + now.minute();
  return decimalTime;
}
```

Summary

In addition to the modules here, you will find lots of other useful modules on the web sites of companies like Adafruit and SparkFun. The web sites also include some information on how to use the modules and their specifications. If you find a module you would like to make use of, the first step is to research how you could use it. As well as the datasheets and tutorial information on the supplier’s web site, you will often find instructions on building the projects if you search for the module on the Internet.

8

Hacking with Sensors

Chapters 6, 7, and 8 all overlap somewhat, as many sensors are also modules and both can often be used with an Arduino.

In this chapter, we will look at how to use a range of sensors, whether with a little supporting electronics or as an input to an Arduino, or sometimes both.

How to Detect Noxious Gas

In this section, you will use a methane sensor (Figure 8-1).

While they look like they should be expensive, these sensors are really quite low cost. They include a small heater (connected between the two H connections) and a catalytic sensing element whose resistance changes depending on the concentration of methane. Although the project will run on batteries, it will burn through them pretty quickly because these sensors have a heating element that will consume 150 to 200 mA.

The sensing of methane does have lots of sensible scientific and industrial uses. However, we will use this technological know-how for the puerile activity of … detecting farts.

You Will Need

To experiment with this gas sensor, you will need the following items.

Quantity	Names	Item	Appendix Code
1	D1	LED	K1
1	R1	10kΩ trimpot	K1
1	R2	10kΩ resistor	K2
1	R3	470Ω resistor	K2
1	IC1	LM311 comparator	S7

Quantity	Item	Appendix Code
1	Methane sensor MQ-4	M11
1	Piezo buzzer (with own oscillator)	M10
1	Solderless breadboard	T5
	Solid-core jumper wire	T6
1	4 × AA battery holder	H1
1	4 × AA batteries	
1	Battery clip	H2
1	* Arduino Uno/Leonardo	M2/M21
1	* USB lead; Type B for Uno, Micro USB for Leonardo	

* Only required if you want to connect the detector to an Arduino.

The piezo sounder must be of the type that includes its own oscillator circuit and will work at 6V.

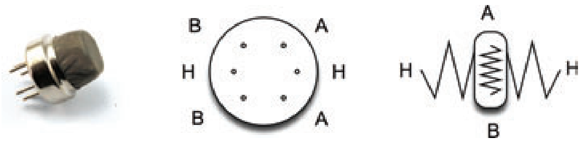

Figure 8-1 A methane sensor

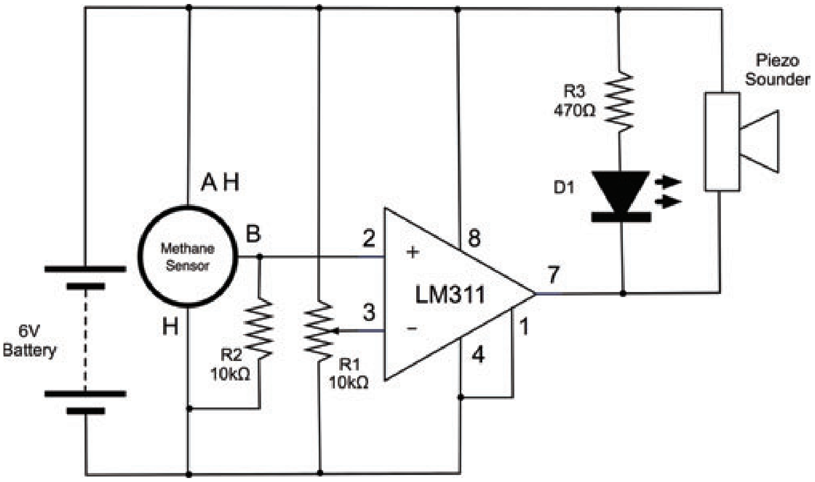
The LM311 Comparator

Figure 8-2 shows the schematic diagram for the gas detector.

The key to this circuit is the comparator IC (LM311). Comparators, as the name suggests, compare voltages. If the voltage at its "+" connection is greater than the voltage at its "–"

Figure 8-2 Schematic diagram for the gas detector



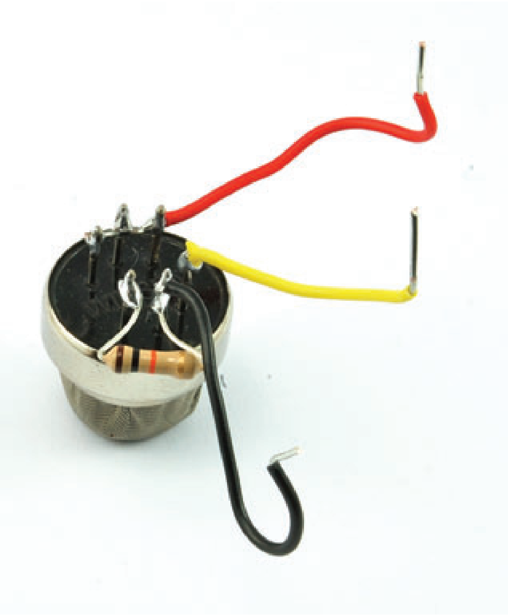
connection, then its output turns on. In this case, that will light the LED and sound a buzzer.

The trimpot supplies a threshold voltage to the negative input of the comparator. To use the gas detector, the trimpot is turned until the LED just goes out. It will come back on if the output from the sensor increases enough to exceed the value at the comparator's negative input.

The sensor has rather unusual connections. It has six connections, but some of them are doubled up and connected behind the scenes (see Figure 8-1). The H connectors supply a heating element that warms the catalyst layer between A and B. When methane is detected, the resistance between A and B falls. R2 forms a voltage divider with the sensing element. One benefit of the sensor basically being two resistors—one acting as a heater and the other as a sensor—is that the pin connections are reversible.

The sensor leads are thick and at a strange spacing, so they will not fit in breadboard. For this reason, we solder some leads to them (Figure 8-3).

FIGURE 8-3 Attaching leads to the sensor



Rather than solder wires to all the leads, we can just solder the following connections:

- A red positive supply lead to all the pins on one side of the sensor (the two A pins and one H connection)
- The resistor R2 between B and the GND side of the heater
- A GND lead to the GND side of the heater (black)
- An output lead to B (yellow)

Breadboard

Figure 8-4 shows the breadboard layout for the gas detector, while Figure 8-5 displays the project itself.

The breadboard layout is very straightforward, but do make sure that the IC is the correct way around. When it is all assembled, I will leave you to find your own way of testing it. Just a note that breathing on the sensor will also set it off.

Figure 8-4 Breadboard layout for the gas detector

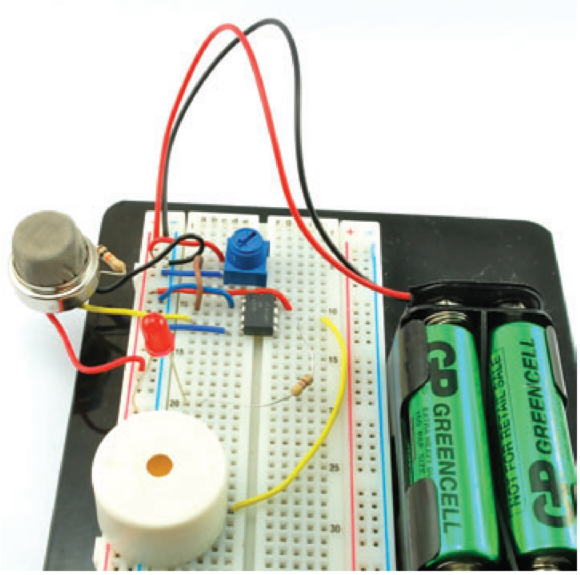
Using a Gas Sensor with an Arduino

In soldering the three leads onto the methane sensor, we have also made something that we can easily attach directly to an Arduino (Figure 8-6).

Connect the positive supply connection from the sensor to 5V on the Arduino, GND on the sensor to GND on the Arduino, and the output of the sensor to A3.

Since this sensor can use up to 200 mA, you must power it from the real 5V and GND connections on the Arduino and not use the trick of powering it from a digital output.

The following sketch ("methane") prints the readings from the sensor into the Serial Monitor. Again, note that if you breathe on the sensor, the reading will increase.



GP GREENCELL

```
// methane

int analogPin = 3;

void setup()
{
  Serial.begin(9600);
  Serial.println("Methane Detector");
}

void loop()
{
  Serial.println(analogRead(analogPin));
  delay(500);
}
```

How to Measure Something's Color

The TCS3200 is a handy little IC for measuring the color of something. There are several different variations on this chip, but they all work the same way. The chip has a transparent case, and dotting its surface are photodiodes with different color filters over them (red, green, and blue). You can read the relative amounts of each primary color.

The easiest way to use the chip is to buy a module like the one shown in Figure 8-7.

This module, which cost less than USD 10, also has four white LEDs that illuminate the object whose color you want to measure, as well as convenient header pins.

Table 8-1 shows the connections on the module and their purpose. With the exception of the power to the LEDs, these connections are taken straight from the IC, so any module you find that uses the TCS3200 is likely to have the same connections, even if they are not quite in the same place.

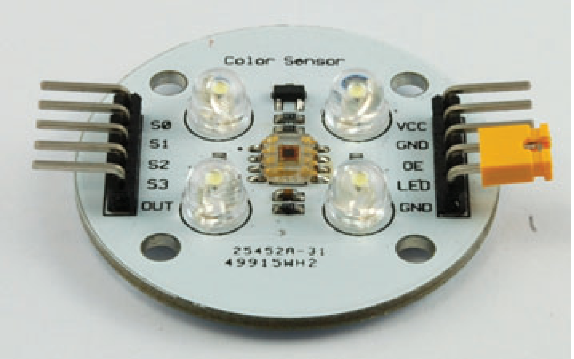

FIGURE 8-7 A light-sensing module

The IC does not produce an analog output, but instead varies the frequency of a train of pulses. You choose which color the pulse frequency corresponds to by changing the values on the digital inputs S2 and S3.

You Will Need

Quantity	Item	Appendix Code
1	Arduino Uno/Leonardo	M2/M21
1	USB lead; Type B for Uno, Micro USB for Leonardo	
1	Color-sensing module	M12
1	Male-to-female jumper set	T12

Pin	Description	Description	Pin
S0	S0 and S1 select the frequency range. Both should be set HIGH.	2.5V to 5.5V	VCC
S1		Ground	GND
S2	Red—S2 and S3 LOW Green—S2 and S3 HIGH Blue—S2 LOW, S3 HIGH White—S2 HIGH, S3 LOW	Output Enable—set to LOW to effectively turn the chip on.	OE
S3		Tie to ground with the attached jumper to turn the LEDs on.	LED
OUT	The output pulses.		GND

TABLE 8-1 Color-Sensing Module Pinout

Construction

Construction is perhaps too strong a word for it. The module will fit directly into the Arduino (Figure 8-8), facing outward. It will make the following connections:

- S0 module to D3 Arduino
- S1 module to D4 Arduino
- S2 module to D5 Arduino
- S3 module to D6 Arduino
- OUT module to D7 Arduino

You will also need three male-to-female jumper leads to connect:

- VCC module to 5V Arduino
- GND module to GND Arduino
- OE module to GND Arduino

Figure 8-9 shows the module sensing colors on a Rubik's cube.

Software

The sketch "color_sensing" demonstrates the use of this module.

```
// color_sensing
int pulsePin = 7;
int prescale0Pin = 3;
int prescale1Pin = 4;
int colorSelect0pin = 5;
int colorSelect1pin = 6;
```

The pins are named according to their function rather than using the module pin names.

The "setup" function sets the appropriate pin modes and then sets both the "prescale" pins that control the

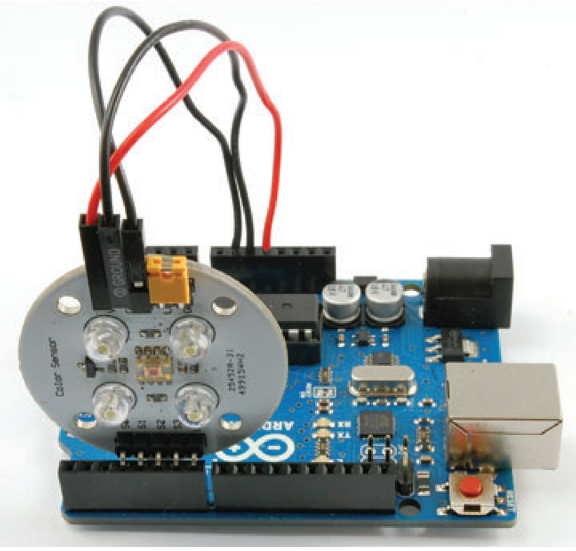

FIGURE 8-8 A light sensor attached to an Arduino

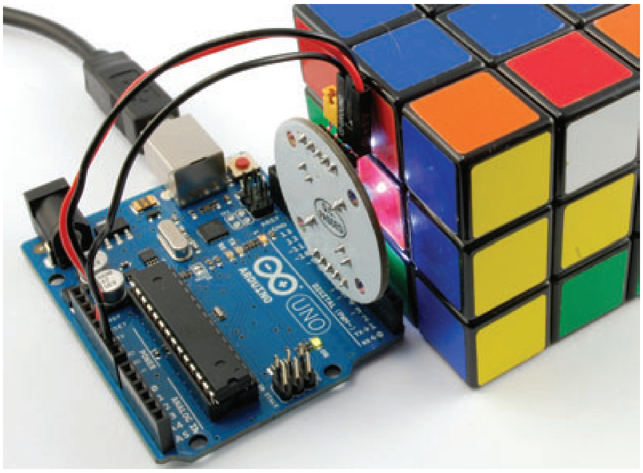

FIGURE 8-9 Sensing colors on a Rubik's cube

output frequency range to HIGH, starts serial communication, and then displays a welcome message.

```
void setup()
{
  pinMode(prescale0Pin, OUTPUT);
  pinMode(prescale1Pin, OUTPUT);
  // set maximum prescale
  digitalWrite(prescale0Pin, HIGH);
  digitalWrite(prescale1Pin, HIGH);
  pinMode(colorSelect0pin, OUTPUT);
  pinMode(colorSelect1pin, OUTPUT);
  pinMode(pulsePin, INPUT);
  Serial.begin(9600);
  Serial.println("Color Reader");
}
```

The “loop” function reads the three different colors (more on that later) and displays a message depending on the dominant color. Note that the lower the value, the brighter that particular color.

```
void loop()
{
  long red = readRed();
  long green = readGreen();
  long blue = readBlue();
  if (red < green && red < blue)
  {
    Serial.println("RED");
  }
  if (green < red && green < blue)
  {
    Serial.println("GREEN");
  }
  if (blue < green && blue < red)
  {
    Serial.println("BLUE");
  }
  delay(500);
}
```

Each of the functions—“readRed”, “readGreen”, “readBlue”, and “readWhite”—just call a function “readColor” with the appropriate values for S2 and S3.

```
long readRed()
{
  return (readColor(LOW, LOW));
}
```

The function “readColor” first sets the appropriate pins for the color and records a start time in the variable “start”. It then waits for 1000 pulses to happen. Afterward, it returns the difference between the current time and the start time.

```
long readColor(int bit0, int bit1)
{
  digitalWrite(colorSelect0pin, bit0);
  digitalWrite(colorSelect1pin, bit1);
  long start = millis();
  for (int i=0; i< 1000; i++)
  {
    pulseIn(pulsePin, HIGH);
  }
  return (millis() - start);
}
```

Although not actually used, there is also a function in the sketch that writes the color values to the Serial Monitor.

```
void printRGB()
{
  Serial.print(readRed()); Serial.print("\t");
  Serial.print(readGreen()); Serial.print("\t");
  Serial.print(readBlue()); Serial.print("\t");
  Serial.println(readWhite());
}
```

How to Detect Vibration

Piezo vibration sensors, like the one from SparkFun shown in Figure 8-10, are very easy to use with an Arduino.

The sensors are a thin strip of piezoelectric material with a rivet in the end acting as a weight. When there is a vibration, the weight moves, stressing the piezo material that produces a spike in voltage. Measured with the right test equipment, this spike can be as high as 80V. However, because we are going to connect it to an analog input on an Arduino, the resistance of that input will be sufficient to damp the voltage to a level that will not harm our Arduino.

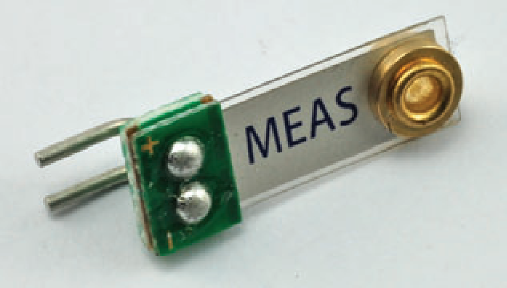

Figure 8-10 A piezo vibration sensor

You Will Need

To detect vibration with your piezo sensor, you will need the following items.

Quantity	Item	Appendix Code
1	Arduino Uno/Leonardo	M2/M21
1	USB lead; Type B for Uno, Micro USB for Leonardo	
1	Piezo vibration sensor	M13
1	LED	K1
1	220Ω resistor	K2

Construction

The piezo sensor is another very Arduino-friendly sensor. It can be just plugged into the Arduino sockets. In this case, it is plugged into pins A0 and A1. A0 will be set to an output LOW and used to provide the ground connection to the sensor (Figure 8-11). Note that the module is marked with a "+" on one side. Connect this side to "A1".

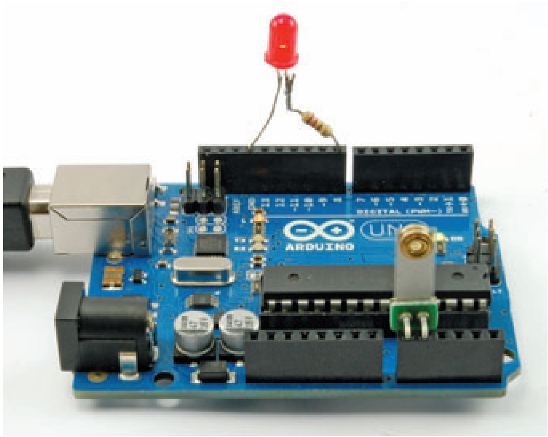

FIGURE 8-11 Sensing vibration with an Arduino

The LED is joined to a resistor as described back in Chapter 6. This can then be plugged into sockets 8 and GND on the Arduino, with the positive connection of the LED connected to 8.

Software

The software that follows uses the technique of calibrating itself as it starts, to get the "no vibration" reading from the sensor. It then waits until the sensor reading exceeds the threshold set, at which point it lights the LED. Pressing the Arduino "reset" button will cause the sensor to detect movement again.

```
// vibration_sensor

int gndPin = A0;
int sensePin = 1;
int ledPin = 8;
```

After defining the pins to use, we then define two variables. The variable "normalReading" is used during calibration (more on that in a minute), and the variable "threshold" should be set to the amount that the analog reading is allowed to exceed "normalReading" by before the LED is turned on.

```
int normalReading = 0;
int threshold = 10;
```

The "setup" function sets the appropriate pin modes and then calls the "calibrate" function to find the reading for the sensor when there is no vibration.

```
void setup()
{
  pinMode(gndPin, OUTPUT);
  digitalWrite(gndPin, LOW);
  pinMode(ledPin, OUTPUT);
  normalReading = calibrate();
}
```

The “loop” function simply takes a reading and checks to see if it has exceeded the threshold. If it has, it turns the LED on.

```
void loop()
{
  int reading = analogRead(sensePin);
  if (reading > normalReading + threshold)
  {
    digitalWrite(ledPin, HIGH);
  }
}
```

To calibrate the sensor, 100 readings are made with a one-millisecond delay between each reading, and the average is returned. A variable of type “long” is used to hold the total, as this number may be too big to fit in the usual “int” type.

```
int calibrate()
{
  int n = 100;
  long total = 0;
  for (int i = 0; i < n; i++)
  {
    total = total + analogRead(sensePin);
    delay(1);
  }
  return total / n;
}
```

How to Measure Temperature

A number of different sensor ICs are designed for measuring temperature. Perhaps the simplest to use is the TMP36 (Figure 8-12).

You can experiment with the sensor, just printing the temperature to the Serial Monitor, or you can combine the sensor with the relay module we made in Chapter 6.

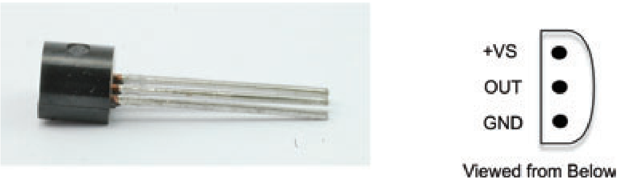

Figure 8-12 The TMP36

You Will Need

To use this temperature measurement IC, you will need the following items.

Quantity	Item	Appendix Code
1	Arduino Uno/Leonardo	M2/M21
1	USB lead; Type B for Uno, Micro USB for Leonardo	
1	TMP36 temperature sensor IC	S8

Construction

The TMP36 has just three pins, two for the power supply and one analog output. The power supply needs to be between 2.7V and 5.5V, making it ideal for use with the 5V of an Arduino. In fact, we can supply the power to it through digital outputs and just plug the whole chip into three pins on the analog connector of the Arduino (Figure 8-13).

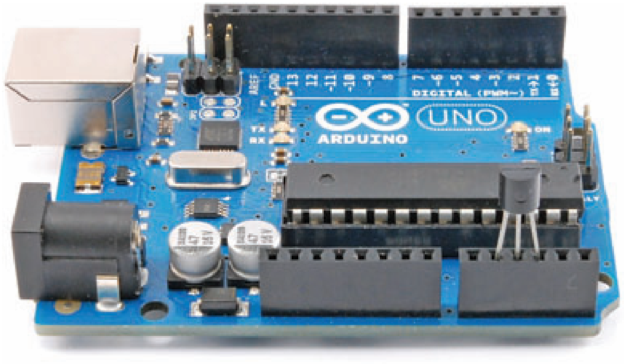

Figure 8-13 The TMP36 attached to an Arduino

Software

The sketch ("temperature_sensor") follows what should now be a fairly familiar pattern. The pins are defined, and then in the "setup" function the output pins that provide power to the sensor are set to LOW for GND and HIGH for the positive supply.

```
// temperature_sensor

int gndPin = A1;
int sensePin = 2;
int plusPin = A3;

void setup()
{
  pinMode(gndPin, OUTPUT);
  digitalWrite(gndPin, LOW);
  pinMode(plusPin, OUTPUT);
  digitalWrite(plusPin, HIGH);
  Serial.begin(9600);
}
```

The main loop reads the value from the analog input and then does a bit of arithmetic to calculate the actual temperature.

First, the voltage at the analog input is calculated. This will be the raw value (between 0 and 1023) divided by 205. It is divided by 205 because a span of 1024 values occupies 5V, or 1024 / 5 = 205 per volt.

The TMP36 outputs a voltage from which the temperature in degrees C can be calculated from the equation:

tempC = 100.0 * volts – 50

For good measure, the sketch also converts this into degrees F and prints both out to the Serial Monitor.

```
void loop()
{
  int raw = analogRead(sensePin);
  float volts = raw / 205.0;
  float tempC = 100.0 * volts - 50;
  float tempF = tempC * 9.0 / 5.0 + 32.0;
  Serial.print(tempC);
  Serial.print(" C ");
  Serial.print(tempF);
  Serial.println(" F");
  delay(1000);
}
```

How to Use an Accelerometer

Tiny accelerometer modules (Figure 8-14) are now available at low cost. The two models shown are very similar, both being 5V compatible and providing analog outputs for each axis. The one on the left is from Freetronics (www.freetronics.com/am3x) and the one on the right is from Adafruit (www.adafruit.com/products/163).

These modules are three axis accelerometers that measure the force applied to a tiny weight inside the chip. Two of the dimensions, X and Y are parallel to the modules PCB. The third dimension (Z) is at 90 degrees to the module’s surface. There will normally be a constant force acting on this dimension due to gravity. So if you tip the module, the effect of gravity starts to increase on the dimension in which you tip it (see Figure 8-15).

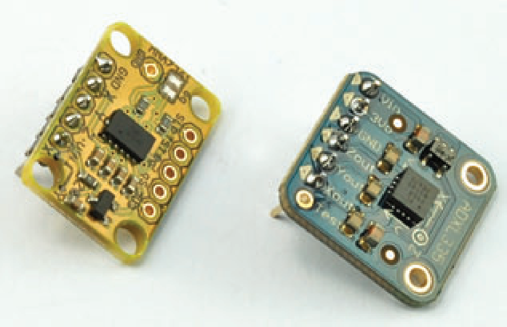

FIGURE 8-14 Accelerometer modules

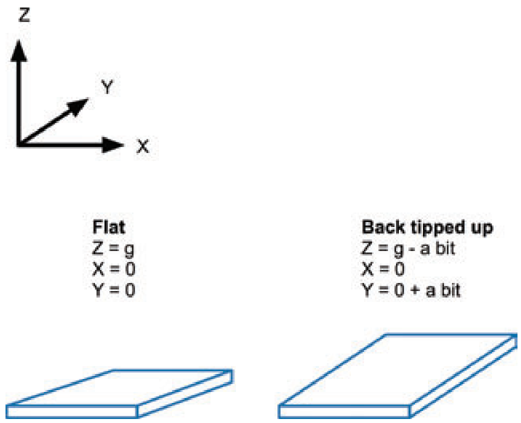

FIGURE 8-15 The effect of gravity on the accelerometer

As a vehicle to test one of these accelerometers, we are going to build an electronic version of the children's game of egg and spoon. The idea behind this is to use the accelerometer to detect the level of tilt of the "spoon" and flash an LED when it starts to be in danger of losing the egg. A buzzer sounds when the level of tilt is extreme enough for the egg to have fallen off (Figure 8-16).

You Will Need

To participate in an Arduino and spoon race, you will need the following items.

Quantity	Item	Appendix Code
1	Arduino Uno/Leonardo	M2/M21
1	USB lead; Type B for Uno, Micro USB for Leonardo	
1	Accelerometer	M15
1	Piezo buzzer	M3
1	LED	K1
1	220Ω resistor	K2
1	Battery clip to 2.1mm jack adapter	H9
1	Wooden spoon	
1	PP3 9V battery	

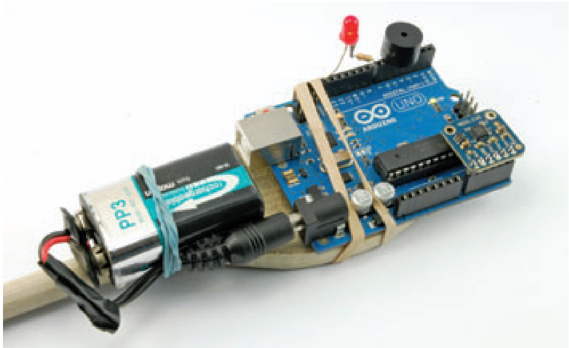
Construction

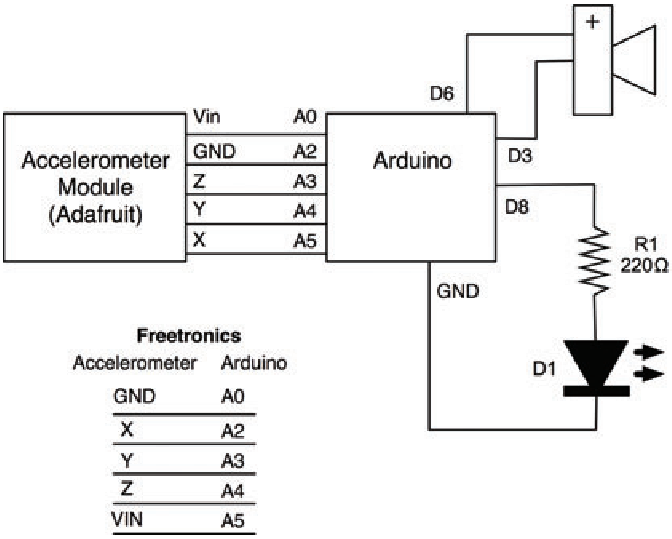
With a bit of thought, both of the accelerometer modules are capable of being plugged directly into the Arduino, as are the buzzer and LED. You should program the Arduino with the right sketch for the accelerometer module you are using before you attach the module, just in case some of the pins on the A0 to A5 connector are set to be outputs from a previous sketch.

Figure 8-17 shows the schematic diagram for the Arduino Egg and Spoon.

As you can see from Figure 8-18, all the components fit into the sockets on

FIGURE 8-16 An Arduino and spoon race





Freetronics

Accelerometer	Arduino
GND	A0
X	A2
Y	A3
Z	A4
VIN	A5

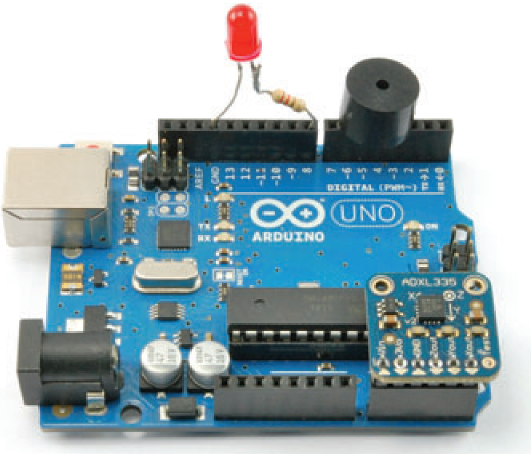
FIGURE 8-17 The schematic diagram for the Arduino Egg and Spoon

the Arduino. The LED/resistor combo is the same as we used in Chapter 6. The positive end goes to digital pin 8 on the Arduino and the negative end to GND. The buzzer fits between pins D3 and D6—D6 being connected to the positive end of the buzzer. If the pins on your buzzer are at a different spacing, then you can pick other pins, but remember to change the variables "gndPin2" and "buzzerPin" to whatever pins you end up using.

Both of the accelerometer modules will fit in the Arduino sockets A0 to A5, as shown in Figure 8-18. However, their pin allocations are quite different.

The project is powered from a 9V battery using an adapter, and the Arduino and battery are attached to the spoon with rubber bands.

FIGURE 8-18 The components attached to the Arduino



Software

There are two versions of the sketch provided: "egg_and_spoon_adafruit" and "egg_and_spoon_freetronics". Make sure you get the right one, and then program the Arduino with it BEFORE you attach the accelerometer.

The only difference between the two sketches is the pin allocations.

This is the sketch for the Adafruit version.

We start by defining the pins used.

```
// egg_and_spoon_adafruit
int gndPin1 = A2;
int gndPin2 = 3;
int xPin = 5;
int yPin = 4;
int zPin = 3;
int plusPin = A0;
int ledPin = 8;
int buzzerPin = 6;
```

The two variables “levelX” and “levelY” are used to measure the resting values of acceleration for X and Y if the spoon is level.

```
int levelX = 0;
int levelY = 0;
```

The “ledThreshold” and “buzzerThreshold” can be adjusted to set the degree of wobble before the LED lights and the buzzer sounds to indicate a “dropped egg.”

```
int ledThreshold = 10;
int buzzerThreshold = 40;
```

The “setup” function initializes the pins and then calls the function “calibrate” that sets the values of “levelX” and “levelY”.

```
void setup()
{
  pinMode(gndPin1, OUTPUT);
  digitalWrite(gndPin1, LOW);
  pinMode(gndPin2, OUTPUT);
  digitalWrite(gndPin2, LOW);
  pinMode(plusPin, OUTPUT);
  pinMode(ledPin, OUTPUT);
  pinMode(buzzerPin, OUTPUT);
  digitalWrite(plusPin, HIGH);
  calibrate();
}
```

In the main loop, we read the X and Y accelerations and see how much they have strayed from the values of “levelX” and “levelY”. The “abs” function returns the absolute value of a number, so if the difference is negative, it is turned into a positive value, and it is this that is compared with the thresholds that have been set.

```
void loop()
{
  int x = analogRead(xPin);
  int y = analogRead(yPin);
  boolean shakey = (abs(x - levelX) > ledThreshold || abs(y - levelY) >
ledThreshold);
  digitalWrite(ledPin, shakey);
  boolean lost = (x > levelX + buzzerThreshold || y > levelY + buzzerThreshold);
  if (lost)
  {
    tone(buzzerPin, 400);
  }
}
```

The only complication in the “calibrate” function is that we must wait for 200 milliseconds before we can take the readings. This gives the accelerometer time to turn on properly.

```
void calibrate()
{
  delay(200); // give accelerometer time to turn on
  levelX = analogRead(xPin);
  levelY = analogRead(yPin);
}
```

How to Sense Magnetic Fields

Sensing a magnetic field is made easy using a three-pin sensor IC like the A1302 linear hall effect sensor. You can use this chip in very much the same way as we did the TMP36 temperature sensor in the section “How to Measure Temperature” earlier in this chapter.

You Will Need

To use this temperature measurement IC, you will need the following items.

Quantity	Item	Appendix Code
1	Arduino Uno/Leonardo	M2/M21
1	USB lead; Type B for Uno, Micro USB for Leonardo	
1	A1302 linear hall effect sensor	S12

Construction

Just like the TMP36, the A1302 has just three pins, two for the power supply and one analog output. The power supply needs to be between 4.5V and 6V, making it ideal for use with the 5V of an Arduino.

In fact, we can supply the power to it through digital outputs and just plug the whole chip into three pins on the analog connector of the Arduino (Figure 8-19). The chip should be oriented with the dot facing outward.

Program the Arduino with the sketch before you plug in the sensor, in case A1 is set to be an output.

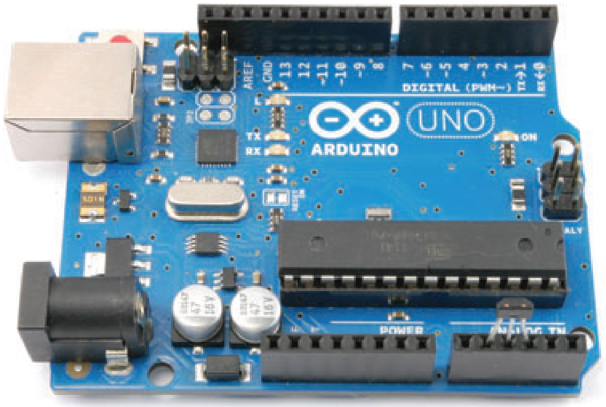


FIGURE 8-19 The A1302 magnetic sensor attached to an Arduino

Software

The sketch for the magnetic sensor is very similar to that of the temperature sensor.

First, the three pins are set up: digital pins 15 and 17 (A0 and A2), and A1 is set as the sensor pin.

```
// magnetic_sensor

int gndPin = A1;
int sensePin = 2;
int plusPin = A3;

void setup()
{
  pinMode(gndPin, OUTPUT);
  digitalWrite(gndPin, LOW);
  pinMode(plusPin, OUTPUT);
  digitalWrite(plusPin, HIGH);
  Serial.begin(9600);
}
```

The main loop just takes the raw reading and sends it to the Serial Monitor.

The device is not terribly sensitive, but if you hold a magnet next to it you should see a change in the reading coming from the Serial Monitor.

```
void loop()
{
  int raw = analogRead(sensePin);
  Serial.println(raw);
  delay(1000);
}
```

Summary

There are many other sensors out there, and many will interface to an Arduino quite easily using an analog input, or employing pulse length, letting you adapt the sketches used for other sensors to different sensors.

In the next chapter, we will change tack and look at sound and audio electronics.

9

Audio Hacks

In this chapter, you will look at audio electronics and find out how to make and amplify sounds so you can drive a loudspeaker.

You will also discover how to hack an FM transmitter intended for use with MP3 players in the car, so that it works as a surveillance bug.

First though, we will look at the more mundane topic of audio leads, how to use them, mend them, and make your own.

Hacking Audio Leads

Ready-to-use audio leads are pretty cheap to buy unless you go for the high-end connectors. Sometimes though, if you need a lead in a hurry, or an unusual lead, it helps to know how to wire one up from parts in your junk box or from connectors you have bought.

Many items of consumer electronics are supplied with a range of leads, and you do not always need them for use with the item you bought. Keep them in your junk box since you never know when you might need to make some kind of lead.

Figure 9-1 shows a selection of audio plugs, some designed to have leads soldered to them, and others that have plastic moldings around the lead and cable, which cannot be soldered to. Plugs with plastic moldings around them are still useful, however. It just means you will have to cut and strip the wire that leads to the plug rather than solder it to the plug itself.

General Principals

Audio leads carry audio signals, often on their way to an amplifier, and the last thing you want is for them to pick up electrical noise that will affect the quality of the sound. For this reason, audio leads are normally screened (see Figure 9-2).

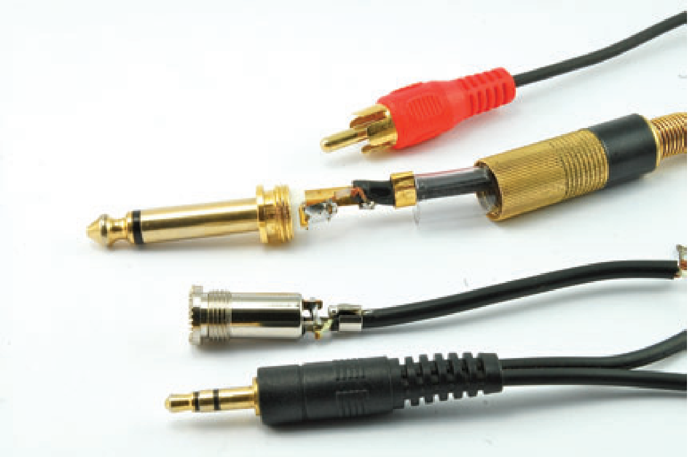

Figure 9-1 A variety of audio plugs

The audio signal itself (or two audio signals for stereo) is carried on insulated multi-core wires that are then enclosed in an outer conductive sheath of screening wire that carries the ground connection.

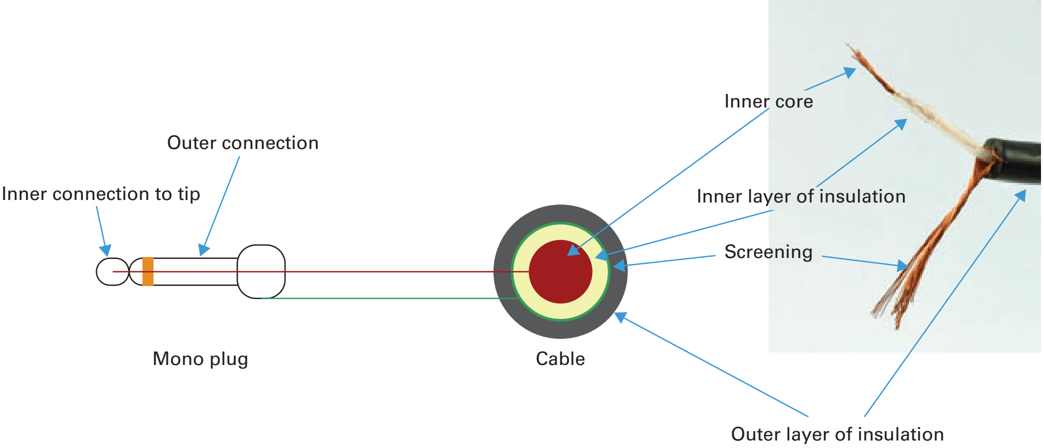

Figure 9-2 A screened audio lead

Inner core
Outer connection
Inner connection to tip
Inner layer of insulation
Screening
Mono plug
Cable
Outer layer of insulation

The exception to this is for leads to loudspeakers. These are not screened because the signal has been amplified to such a degree that any noise the speaker cables might pick up would be undetectable.

Soldering Audio Connectors

Stripping audio connectors is made more difficult by the fact that there is more than one layer of insulation. It is very easy to accidentally cut through the shielding. Nicking the outer insulation all around before stripping it will usually help with this problem.

Figure 9-3 shows the sequence involved in soldering a screened lead to a 6.3mm jack plug of the sort often used to connect an electric guitar to its amplifier.

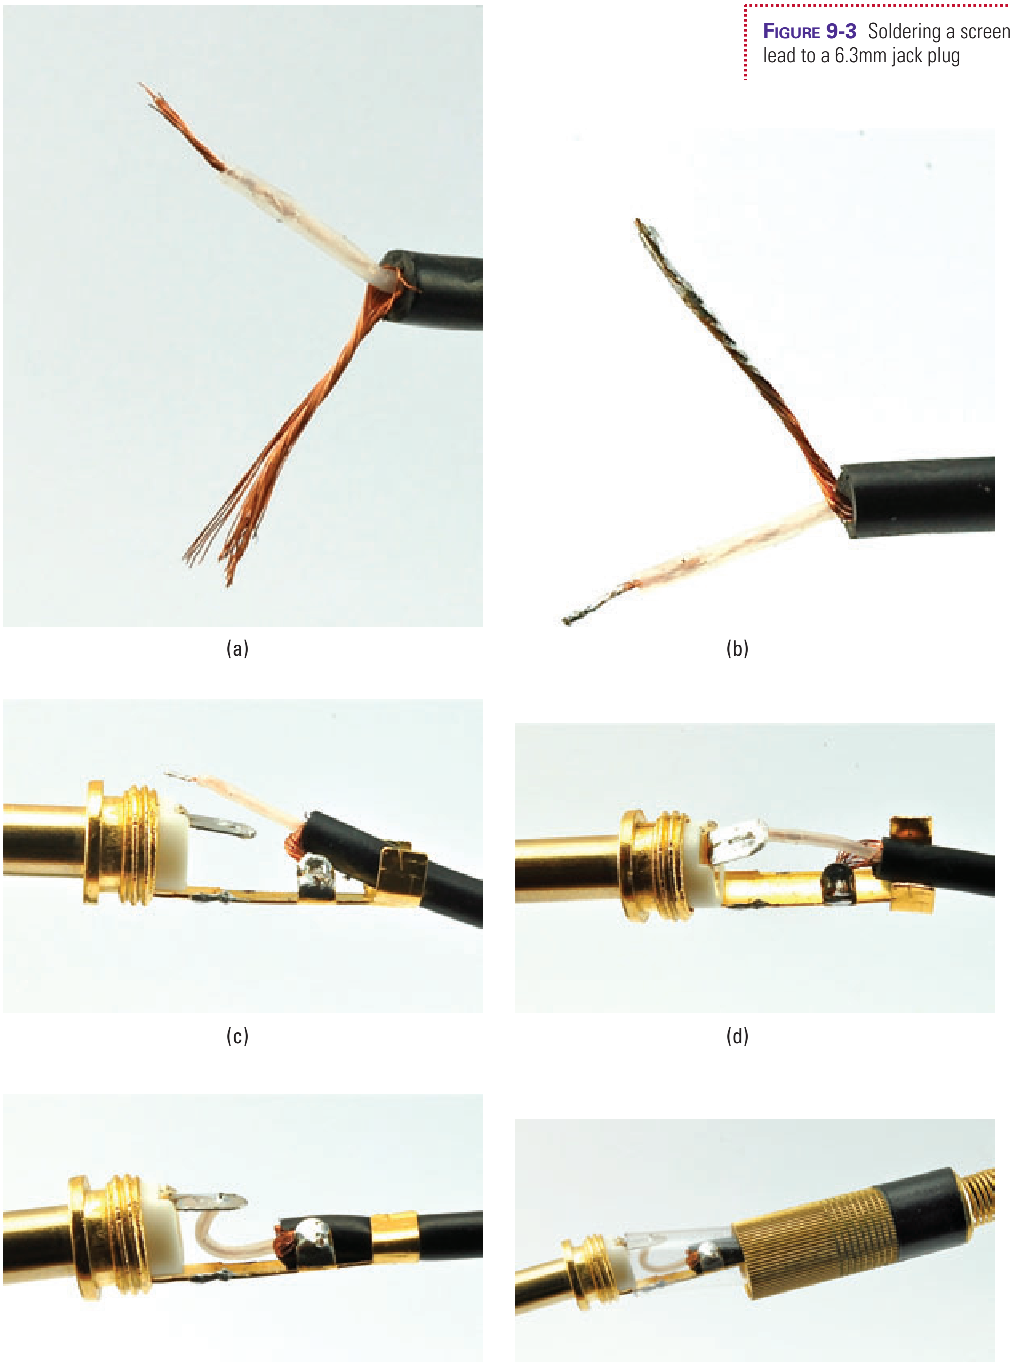
The first step is to strip off the outer insulation about 20mm (a bit less than an inch) from the end of the lead and tease the shielding wires around to one side of the lead and twist them together. Strip about 5mm of insulation off the inner core insulation (Figure 9-3a). Then, tin both bare ends (Figure 9-3b).

The jack plug has two solder tags: one for the outer part of the plug and one connected to the tip. Both will usually have holes in them. Figure 9-3c shows the screening trimmed to a shorter length and pushed through the hole ready to solder. Once the screening is soldered into place, solder the inner core to the solder tag for the tip (Figure 9-3d).

These wires are quite delicate, so make sure the inner core wire has some extra length (as shown in Figure 9-3e) so that if the plug flexes, it will not break the connection. Notice that the strain relief tabs at the end of the plug have been pinched around the outer insulation. Finally, the plug will often have a plastic sleeve that protects the connections. Slide this over the connections and then screw in the plug casing.

Tip

If there is a plug on the other end of the lead, remember to push the new plug enclosure and plastic sleeve onto the lead BEFORE you solder the second plug on, otherwise you will end up having to unsolder everything to put it on. The author has made this mistake more times than he cares to admit.



(a) (b)

(c) (d)

(e) (f)

Figure 9-3 Soldering a screened lead to a 6.3mm jack plug

Converting a Stereo Signal to Mono

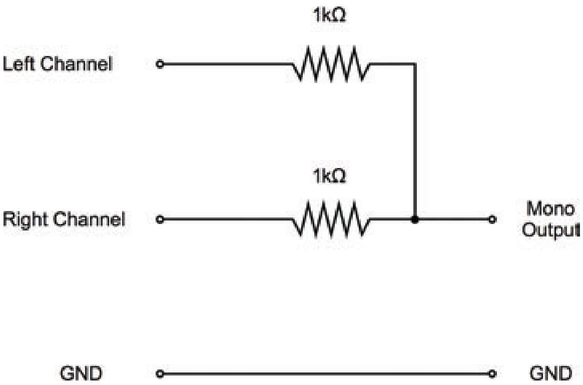


FIGURE 9-4 Mixing stereo to mono

Stereo audio is made up of two slightly different audio signals that give the stereo effect when played through two separate speakers. Sometimes, you have a stereo output that you want to input to a single channel (mono) amplifier.

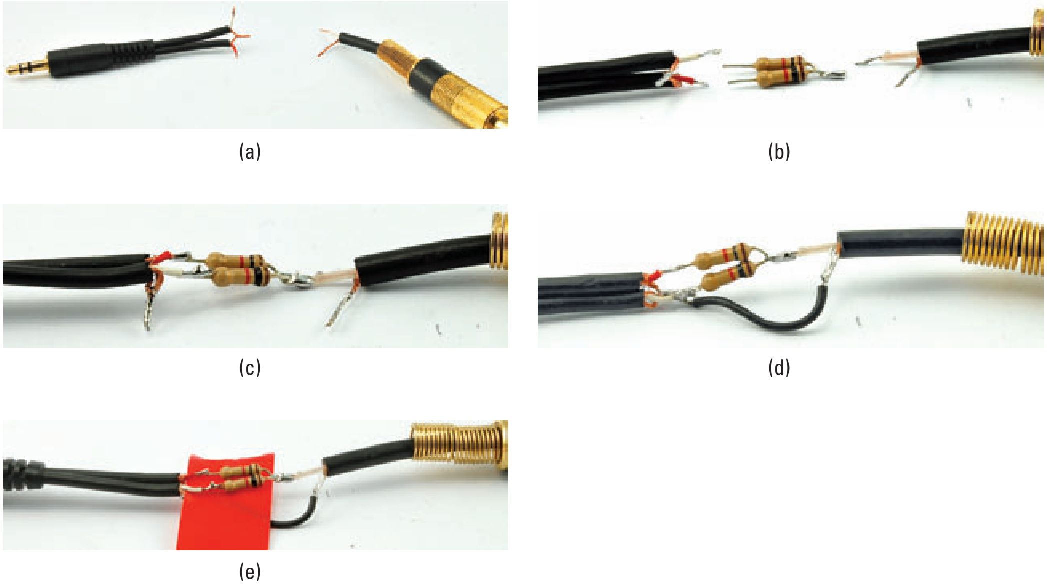
You could use just one of the channels of the stereo signal (say, the left channel), but then you will lose whatever is on the right channel. So a better way of converting stereo to mono is to use a pair of resistors to mix the two channels into one (Figure 9-4).

Looking at the schematic of Figure 9-4, you could be forgiven for thinking all you need to do is connect the left and right channels to each other directly. This is not a good idea, because if the signals are very different, there is the potential for a damaging current to flow from one to the other.

As an example, we could use the mono 6.3mm jack we just soldered leads to, and combine it with a pair of resistors and a stereo 3.5mm jack plug so we could, for example, plug an MP3 player into a guitar practice amplifier.

Figure 9-5 shows the steps involved in this. To make it easier to photograph, the author's lead is made very short. You will

FIGURE 9-5 Making a lead



(a) (b) (c) (d) (e)

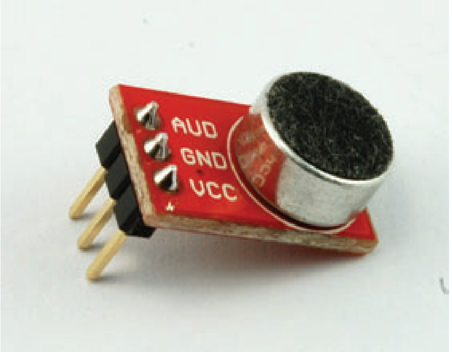
probably want to make yours longer. This is not a problem, unless you plan to make it longer than a few yards or meters.

The 3.5mm plug is of the plastic molded variety, reclaimed from some unwanted lead. The first step is to strip both leads (Figure 9-5a). Note that the stereo plug has two screened connections in one twin cable. The screened ground connections of both channels of the stereo plug can be twisted together.

Tin the ends of all the leads, and then solder the resistors together, as shown in Figure 9-5b.

Next, solder the stereo and mono leads to the resistors, as shown in Figure 9-5c, and cut and tin a short length of wire to bridge the ground connections. Solder it into place (Figure 9-5d) and then wrap everything in insulating tape, taking care to put tape in between any places where wires could short together (Figure 9-5e).

Figure 9-6 A microphone module



How to Use a Microphone Module

Microphones (mics) respond to sound waves, but sound waves are just small changes in air pressure, so it is not surprising that the signal you get from a mic is usually very faint. It requires amplification to bring it up to a useable level.

While it is perfectly possible to make a little amplifier to boost the signal from your mic, you can also buy a mic module that has an amplifier built in. Figure 9-6 shows such a module.

The mic module just requires a supply voltage between 2.7V and 5.5V. This makes it ideal for interfacing with an Arduino.

In Chapter 11, you will find out a bit more about oscilloscopes. But for now, here is a sneak preview of what an oscilloscope will display (see Figure 9-7) when connected to the mic module while a constant tone is being generated and the module is supplied with 5V.

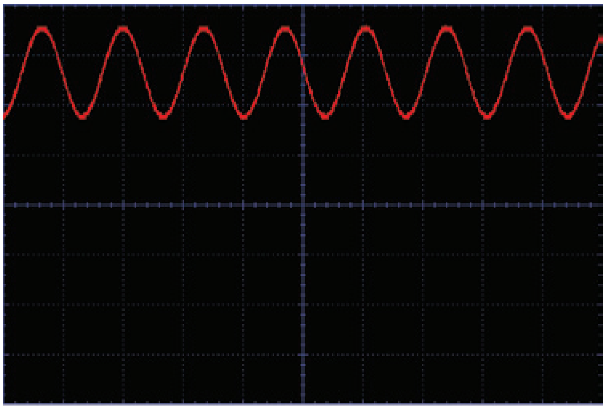


Figure 9-7 The output of the microphone module

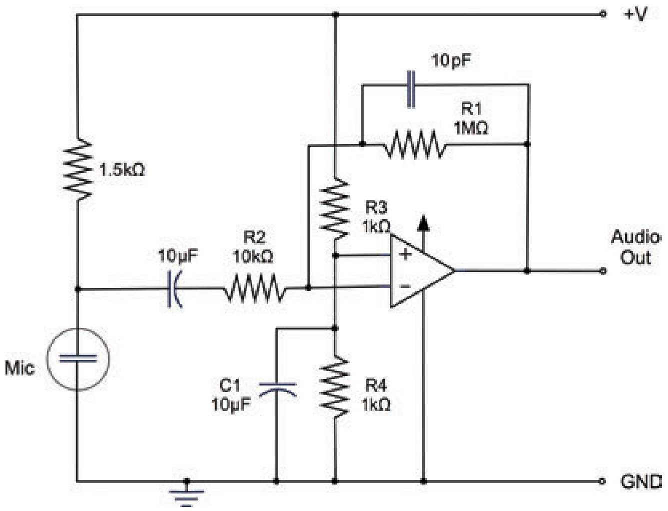
The oscilloscope is displaying the sound. In this case, a constant and rather irritating tone of 7.4 kHz. The horizontal axis is time, and each blue square represents 100 microseconds. The vertical axis is the voltage and each square is 1V. The output of the mic module is a voltage that varies very quickly between about 1.8V and 3.5V. If you draw a horizontal line straight down the middle of the waveform, it would be at about 2.5V. This is halfway between 0V and 5V. So if there is no sound at all, there will just be a flat line at 2.5V, and as the sound gets louder, the waveform will swing further and further either way. It will not, however, go higher than 5V or lower than 0V. Instead, the signal will clip and become distorted.

Figure 9-8 The schematic diagram for a mic module



The mic module shown is sold by SparkFun (BOB-09964). The schematic for this, along with all its design files have been made public. Figure 9-8 shows a schematic for a typical microphone pre-amp.

The chip at the center of this design has a similar circuit symbol to the comparator you used in the "How to Detect Noxious Gas" section at the beginning of Chapter 8. However, it is not a comparator; it is an amplifier IC of a type known as an "operational amplifier" (or "op amp" for short).

Whereas a comparator turns its output on when the "+" input is higher than the "–" input, an op amp amplifies the difference between the "+" and "–" inputs. Left to its own devices, it amplifies this by a factor of millions. This means that the tiniest signal or noise on the input would be turned into meaningless thrashing of the output from 0 to 5V. To tame the op amp and reduce its amplification factor (called "gain"), something called "feedback" is used.

The trick is to take a portion of the output and feed it into the negative input of the op amp. This reduces the gain to an amount determined by the ratio of R1 to R2, shown in Figure 9-8. In this case, R1 is 1MΩ and R2 is 10kΩ, so the gain is 1,000,000 / 10,000 or 100.

The signal from the microphone is being amplified by a factor of 100. This shows just how weak the signal is in the first place.

The “+” input to the op amp is held halfway between GND and 5V (2.5V) by using R3 and R4 as a voltage divider. C1 helps to keep this constant.

From the schematic, you can see how you could build the module yourself on, say, stripboard. Op amps like the one used (which is a surface-mounted device) are also available in the eight-pin DIP form. However, a module like this will save you a lot of effort and may even turn out cheaper than buying and building a module from scratch.

I realize this is a rather cursory introduction to op amps. These are very useful devices, but unfortunately require more space to explain fully than this book can accommodate. You will find good information on op amps at the Wikipedia site, as well as in books with a more theoretical bent like *Practical Electronics for Inventors*, Third Edition, by Paul Sherz and Simon Monk, which has a chapter devoted exclusively to op amps.

In the next section, we will combine this module with a hacked FM transmitter of the sort used to let you play your MP3 player through your car radio, thus creating an audio “bug.”

How to Make an FM Bug

To make an FM transmitter that will broadcast sound picked up from a microphone to a nearby FM radio receiver would require a lot of effort. We are hackers, so we are going to cheat and take apart an FM transmitter and wire it up to a mic module. Figure 9-9 shows the end result of this hack.

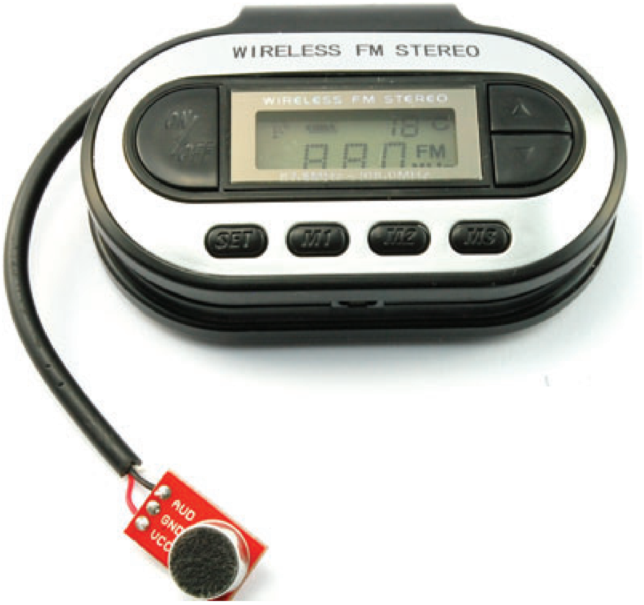


FIGURE 9-9 An FM radio bug

You Will Need

To build the bug, you will need the following.

Quantity	Item	Appendix Code
1	Microphone module	M5
1	* FM transmitter for MP3 players	
1	FM radio receiver	

* For suitable FM transmitters, try searching on eBay using the search terms "fm transmitter mp3 car." Expect to pay about USD 5 and look for the most basic of models. You do not need remote control or an SD card interface. You just want something that has an audio input lead, and for simplicity purposes runs on two AA or AAA batteries (3V).

Construction

This is a very easy project to make. Figure 9-10 shows the schematic diagram for the bug.

The 3V battery of the FM transmitter is used to provide power to the mic module, and the single output of the mic module is connected to both the left and right inputs of the stereo FM transmitter.

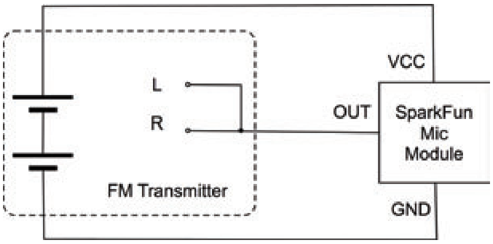

Figure 9-10 Schematic diagram for the radio bug

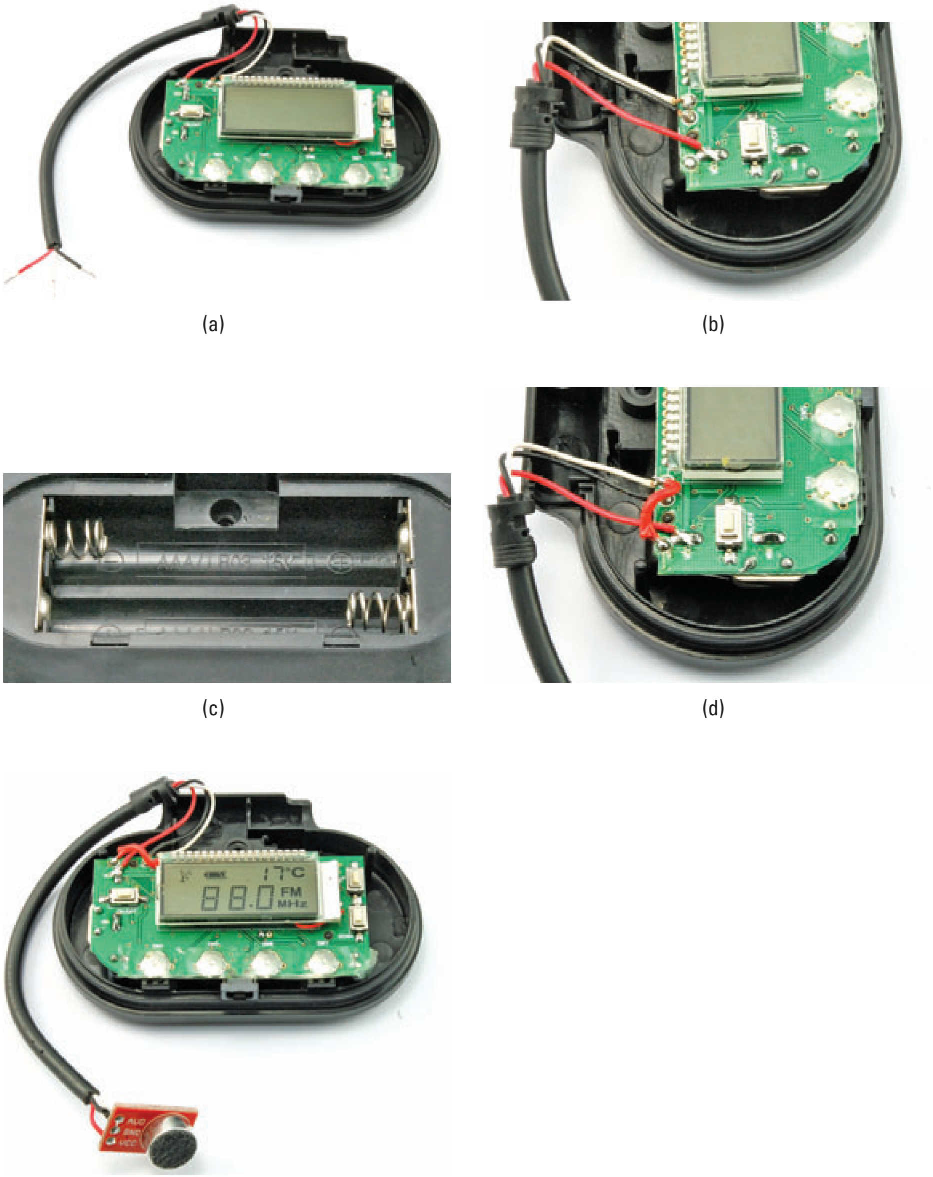
Figure 9-11 shows how the FM transmitter is modified to connect the mic module to it.

The first step is to unscrew any screws that hold the case together and pull it apart. Then, chop off the plug, leaving most of the lead in place since the lead often doubles as an antenna in these devices. Strip and tin the three wires inside the lead (Figure 9-11a).

Looking at the three wires, in Figure 9-11a, the red wire is the right signal, the white the left, and the black ground. This is a common convention, but if you are not sure it applies to your transmitter, you can check by stripping the wires on the plug end of the lead you cut off and using the continuity setting on your multimeter to see which lead is connected to what on the plug. The farthest tip and next ring should be the left and right signals, and the metal nearest the plastic should be the ground connection.

We are going to leave the ground and left connections as they are, but disconnect the wire and connect it to the 3V connection of the battery (Figure 9-11b). In this transmitter, the positive terminal of the battery box underneath the PCB is soldered to the top surface of the PCB.



17°C
88.0 FM MHz
AUD
GND
VCC

(a) (b) (c) (d) (e)

Figure 9-11 Modding the FM transmitter

To find the positive connection, look carefully at the battery box. In Figure 9-11c, you can see that the metal piece on the left of the figure links the negative of the top cell to the positive of the bottom cell. The 3V connection will therefore be the top right connection of the battery box, so trace where this comes out on the top of the PCB. If it is attached by wires, then find an appropriate place for the red wire of the audio jack lead to be joined to it.

Referring back to the schematic diagram of Figure 9-10, we need to make a little wire just to link the left and right channels (Figure 9-11d). When all the changes are complete, it should look like Figure 9-11e.

Testing

Note that the on/off button of the transmitter will have no effect on the power going to the mic module. So to fully turn off the bug, remove the batteries.

To test the module out, set the frequency of the FM transmitter to one not occupied by a radio station and then set the radio receiver to the same frequency. You may well hear the howl of feedback through the radio. To prevent that, take the radio receiver to a different room. You should find that you can hear what is happening in the room with the bug in it pretty clearly.

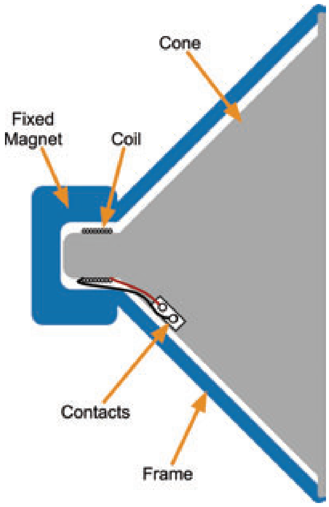
Selecting Loudspeakers

Loudspeakers have remained largely unchanged in design since the early days of radio. Figure 9-12 shows how a loudspeaker works.

The cone (often still made of paper) has a light coil around the end that sits within a fixed magnet attached to the frame of the loudspeaker. When the coil is driven by an amplified audio signal, it moves toward and away from the magnet in time with the audio. This creates pressure waves in the air, producing a sound.

Electronically speaking, a loudspeaker just looks like a coil. When you buy a speaker like this, it will have a number of ohms associated with it. Most speakers are 8Ω, but you can also commonly find 4Ω and 60Ω speakers. If you measure the resistance of the coil of an 8Ω speaker, you should find that it is indeed about 8Ω.

FIGURE 9-12 How a loudspeaker works



Another figure that is normally stated with the speaker is the power. This specifies how hard the loudspeaker can be driven before the coil will get too hot and burn out. For a small loudspeaker such as one you might put in a small radio receiver, values of 250 mW and up are not untypical. As you progress toward the kind of speakers you would use with a hi-fi set, you will see figures in the tens of watts, or even hundreds of watts.

It is very hard to build speakers that can cover the whole range of audio frequencies, which is generally standardized as 20 Hz up to 20 kHz. So you will often find hi-fi speakers that group a number of speakers into a single box. This might be a "woofer" (for low frequencies) and a "tweeter" (for high frequencies). Because woofers cannot keep up with the high frequencies, a module called a "crossover network" is used to separate the low and high frequencies and drive the two types of speakers separately. Sometimes this is taken a step further and three drive units are used: one for bass, one for mid-range tones, and a tweeter for high frequencies.

The human ear can pick out the direction of a high-frequency sound very easily. If you hear a bird tweeting in a tree, you will probably be able to look straight at it without having to think about where it is. The same is not true of low frequencies. For this reason, surround-sound systems often have a single low-frequency "woofer" and a number of other speakers that handle midrange and higher frequencies. This makes life easier, because bass speakers have to be much larger than higher-frequency units in order to push large amounts of air about relatively slowly to produce bass sounds.

How to Make a 1-Watt Audio Amplifier

Building a small amplifier to drive a loudspeaker is made easier by an IC like the TDA7052, which contains pretty much all the components you need, on a chip costing less than $1. In this section, you will make a little amplifier module on stripboard (Figure 9-13).

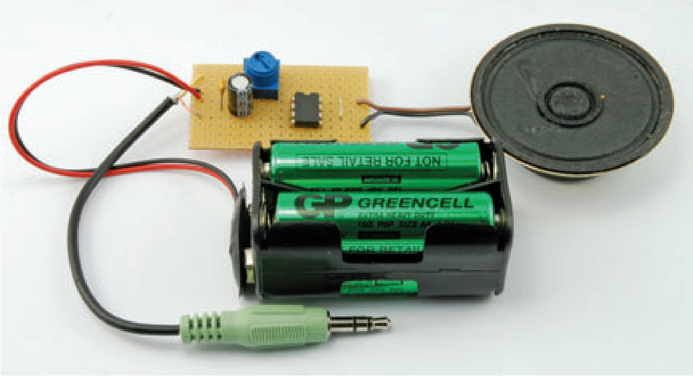


FIGURE 9-13 A 1-watt amplifier module

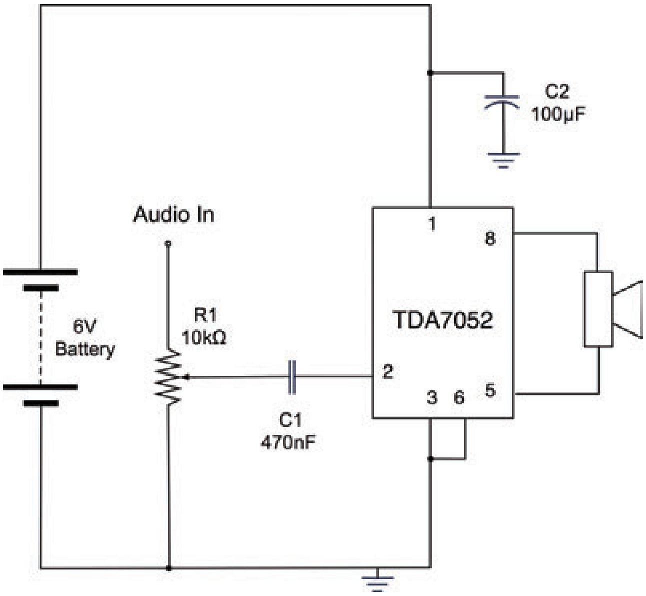

FIGURE 9-14 A typical TDA7052 amplifier schematic

An alternative to making your own amplifier is to buy a ready-made module. You will find these available for a wide range of different powers and in mono and stereo configurations. eBay is a good source for such modules, as are SparkFun (BOB-11044) and Adafruit (product ID 987). These modules often use an advanced type of design called "class-D," which is far more efficient in its use of energy than the module we are going to build.

Figure 9-14 shows the typical schematic for a TDA7052 amplifier.

R1 acts as a volume control, reducing the signal before amplification.

C1 is used to pass the audio signal on to the input to the amplifier IC without passing on any bias voltage that the signal may have from the audio device producing the signal. For this reason, when you use a capacitor like this, it is called a coupling capacitor.

C2 is used to provide a reservoir of charge that can be drawn on quickly by the amplifier when it needs it for very rapid changes in the power supplied to the speaker. This capacitor should be positioned close to the IC.

You Will Need

To build the amplifier module, you will need the following.

Quantity	Name	Item	Appendix Code
1	IC1	TDA7052	S9
1	R1	10kΩ variable resistor	K1, R1
1	C1	470nF capacitor	C3
1	C2	100µF capacitor	K1, C2
1		8Ω speaker	H14
1		Stripboard	H3

Construction

Figure 9-15 shows the stripboard layout for the amplifier module. If you have not used stripboard before, read through the section titled “How to Use Stripboard (LED Flasher)” in Chapter 4.

To build the module, follow the steps shown in Figure 9-16.

First, cut the stripboard to size and make the three cuts in the tracks using a drill bit (Figure 9-16a).

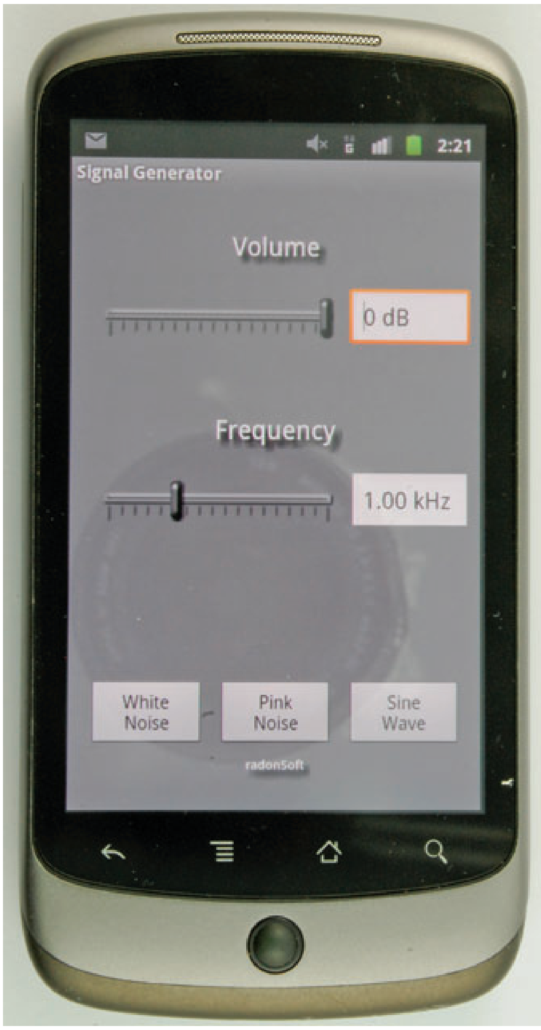
(a) (b)

(c) (d)

Figure 9-16 Building the audio amplifier module

The next step is to solder the link into place, and then the IC, C1, C2, and R1 in that order (Figure 9-16b). It is easiest to solder the components that are lowest to the board first.

Attach leads to the speaker (Figure 9-16c) and finally attach the battery clip and a lead ending in a 3.5mm stereo jack plug (Figure 9-16d). Note that only one channel of the audio lead is used. If you want to use both left and right channels, you should use a pair of resistors (see the section "Hacking Audio Leads" at the beginning of this chapter).



Signal Generator

Volume: 0 dB

Frequency: 1.00 kHz

FIGURE 9-17 A signal generator app

Testing

You can try the amplifier out by plugging it into an MP3 player, or, if you have an Android phone or an iPhone, download a signal generator app like the one shown in Figure 9-17. There are a number of such apps, many of them free, including this one for Android from RadonSoft.

With this, you can play a tone at a frequency you select. By noting when the volume of the speaker starts to drop off, you can work out the useful frequency range of your amplifier module.

How to Generate Tones with a 555 Timer

Back in Chapter 4, you used a 555 timer to blink a pair of LEDs. In this section, we will see how to use a 555 timer IC oscillating at much higher frequencies to generate audio tones.

The pitch will be controlled using a light-dependent resistor (LDR) so that as you wave your hand over the light sensor, the pitch will change in a theremin-like manner.

FIGURE 9-18 Generating tones with a 555 timer IC

Figure 9-18 shows the tone generator built onto breadboard.

Figure 9-19 shows the schematic diagram for the tone generator.

This is similar to the design of the LED flasher in Chapter 4. In this case, instead of two fixed resistors and a capacitor setting the frequency, R1 is the LDR, whose resistance will vary between about 1kΩ and 4kΩ depending on the light falling on it. We need a much higher frequency than our LED flashing circuit—in fact, if we aim for a maximum frequency of around 1 kHz, we need a frequency of about 1000 times what we had before.

FIGURE 9-19 Schematic diagram for a 555 tone generator

The 555 timer oscillates at a frequency determined by the formula:

frequency = 1.44 / ((R1 + 2 * R2) * C)

where the units of R1, R2, and C1 are in Ω and F.

So, if we use a 100nF capacitor for C1, and R2 is 10kΩ, and R1 (the LDR) has a minimum frequency of 1kΩ, then we can expect a frequency of:

1.44 / ((1000 + 20000) * 0.0000001) = 686 Hz

If the LDR's resistance increases to 4kΩ, then the frequency will drop to:

1.44 / ((4000 + 20000) * 0.0000001) = 320 Hz

To calculate the frequency and when deciding what values of R1, R2, and C1 to use, there are online calculators like this one at www.bowdenshobbycircuits.info/555.htm that will calculate the frequency for you.

You Will Need

To build the amplifier module, you will need the following.

Quantity	Name	Item	Appendix Code
1	IC1	555 timer IC	K1, S10
1	R1	LDR	K1, R2
1	R2	10kΩ resistor	K2
1	C1	100nF capacitor	K1, C4
1	C2	10μF capacitor	K1, C5
1		8Ω speaker	H14

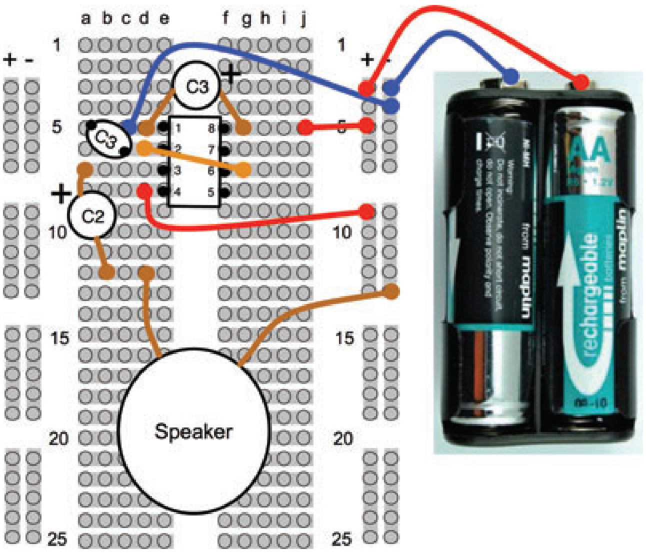

FIGURE 9-20 A signal generator app

Construction

Figure 9-20 shows the breadboard layout for the tone generator.

It would be quite straightforward to build this design onto stripboard. The stripboard layout in the section "How to Use Stripboard (LED Flasher)" in Chapter 4 would be a good starting point.

How to Make a USB Music Controller

Music software like Ableton Live™ is designed to allow USB controllers that emulate a keyboard to control virtual musical instruments and do all kinds of exciting things.

You can use the USB keyboard emulation features of the Arduino Leonardo with an accelerometer so that tilting the board produces a key press of a number between 0 and 8, with 4 being pressed if the board is level, 0 if tilted almost vertically to the right, and 8 being pressed when it is tilted the other way.

The only hardware on the Arduino is the accelerometer (Figure 9-21).

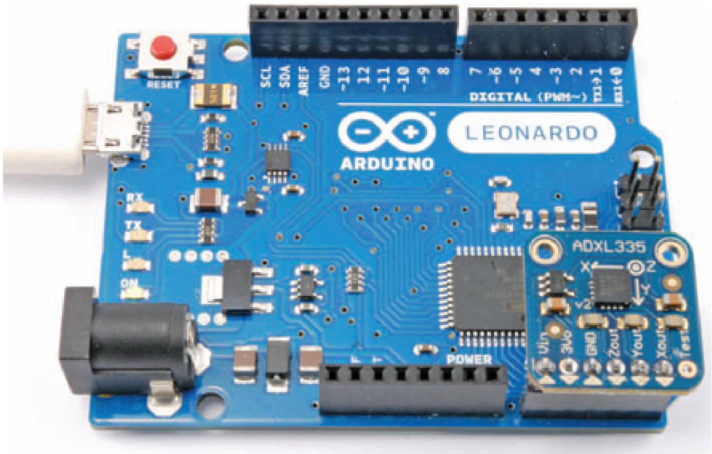

Figure 9-21 A USB music controller

You Will Need

To build this controller, you will need the following items.

Quantity	Item	Appendix Code
1	Arduino Leonardo	M21
1	Micro USB for Leonardo	
1	Accelerometer	M15 (Adafruit version)

Construction

There is actually very little to construct in this project. The schematic is actually the same as in the section titled "How to Use an Accelerometer" in Chapter 8. The Freetronics accelerator will also work, but you will need to change the pin assignments before attaching the accelerometer.

Software

The software for the music controller combines code for sensing the angle of tilt on the X-axis with emulating a keyboard press.

The first step is to assign the pins to be used. As in the section "How to Use an Accelerometer" in Chapter 8, the accelerometer module is powered from output pins.

```
// music_controller

int gndPin = A2;
int xPin = 5;
int yPin = 4;
int zPin = 3;
int plusPin = A0;
```

The variable “levelX” is used during calibration and holds the analog value when the accelerometer is flat.

The “oldTilt” variable contains the old value of the tilt of the board, which is a value between 0 and 8, where 4 means level. The old value is remembered, so that a key press is only sent if the tilt angle changes.

```
int levelX = 0;
int oldTilt = 4;
```

The “setup” function sets the output pins to power the accelerometer, calls “calibrate”, and starts the Leonardo keyboard emulation mode.

```
void setup()
{
  pinMode(gndPin, OUTPUT);
  digitalWrite(gndPin, LOW);

  pinMode(plusPin, OUTPUT);
  digitalWrite(plusPin, HIGH);
  calibrate();
  Keyboard.begin();
}
```

In the main loop, the accelerometer reading is converted to a number between 0 and 8, and if it has changed since the last reading, a key press is generated.

```
void loop()
{
  int x = analogRead(xPin);
  // levelX-70 levelX levelX + 70
  int tilt = (x - levelX) / 14 + 4;
  if (tilt < 0) tilt = 0;
  if (tilt > 8) tilt = 8;
  // 0 left, 4 is level, 8 is right
  if (tilt != oldTilt)
  {
      Keyboard.print(tilt);
      oldTilt = tilt;
  }
}
```

The “calibrate” function takes an initial reading of the acceleration on the X-axis, after waiting 200 milliseconds for the accelerometer to turn on properly.

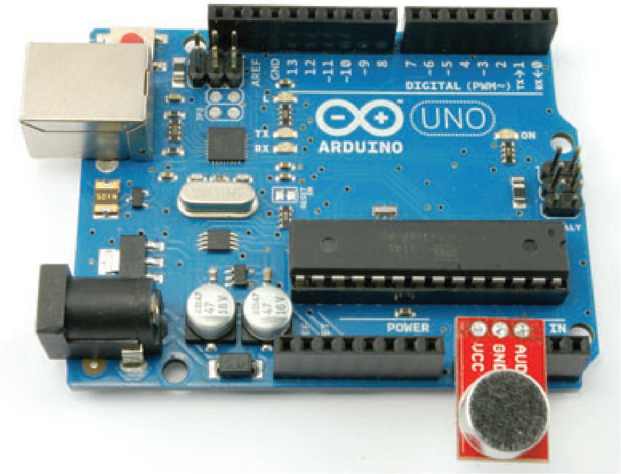
```
void calibrate()
{
  delay(200); // give accelerometer time to turn on
  levelX = analogRead(xPin);
}
```

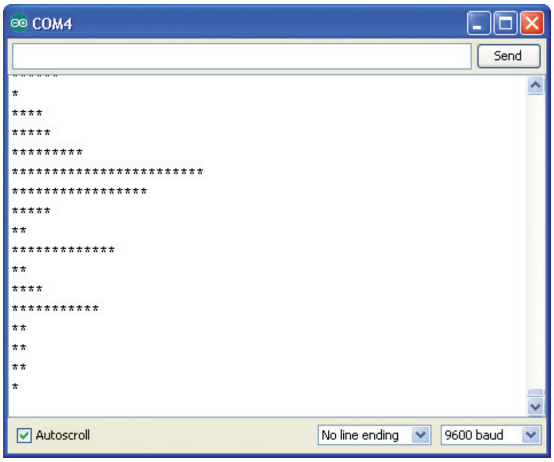
How to Make a Software VU Meter

The mic module you used in the section “How to Make an FM Bug” is also perfectly suited for use with microcontrollers like the Arduino. Figure 9-22 shows the module with pins attached to it and pushed into the analog connector strip of the Arduino.

The mic module can be used to measure the sound level and write a number of “*”s to the Serial Monitor to indicate the loudness of the sound (Figure 9-23).

Figure 9-22 Attaching a mic module to an Arduino





```

*****
**
*************
**
****
***********
**
**
**
*
```

☑ Autoscroll No line ending 9600 baud

Figure 9-23 The Serial Monitor as a VU meter

You Will Need

To build this VU meter, you will need the following items.

Quantity	Item	Appendix Code
1	Arduino Uno/Leonardo	M2, M21
1	USB lead; Type B for Uno, Micro USB for Leonardo	
1	Mic module	M14
1	Header pins (three-way)	H4

Construction

Upload the sketch "vu_meter" before attaching the mic module.

Solder the header pins to the module so they will fit into the Arduino sockets A0 to A2 with the microphone facing outward, as shown in Figure 9-22.

Software

The mic module uses very little current, so for convenience we can use A0 and A1 to provide the power to it.

The sketch begins by defining the pins to use and setting them up in the "setup" function. Serial communication is also started here.

```
// vu_meter

int gndPin = A1;
int plusPin = A0;
int soundPin = 2;

void setup()
{
  pinMode(gndPin, OUTPUT);
  digitalWrite(gndPin, LOW);
  pinMode(plusPin, OUTPUT);
  digitalWrite(plusPin, HIGH);
  Serial.begin(9600);
}
```

The loop function reads the raw value for the analog input A2. The mic module produces an output of 2.5V when there is no signal, and swings above and blows that with the sound's waveform. So to find the "loudness" we need to first subtract 511 from the raw value—511 being equivalent to the 2.5V offset in the raw analog reading that spans from 0 to 1023.

The "abs" function makes any negative number positive and then divides the whole result by 10 to give us a number between 0 and 51 and assigns it to the variable "topLED". We are not actually using LEDs, but you could think of each "*" as being an LED illuminated on a bar graph display.

The "for" loop then prints a number of "*"s equal to the value held in "topLED". Finally, a new line is printed and we delay for 1/10th of a second.

```
void loop()
{
  int value = analogRead(soundPin);
  int topLED = 1 + abs(value - 511) / 10;

  for (int i = 0; i < topLED; i++)
  {
      Serial.print("*");
  }
  Serial.println();
  delay(100);
}
```

Summary

In addition to the how-tos just covered, there are lots of audio modules you can make use of. Low-cost stereo power amplifiers are available from eBay and suppliers like SparkFun and Adafruit.

You can also buy ultra-low-cost amplified speakers intended for computers and reuse them in your projects.

10

Mending and Breaking Electronics

In this chapter, we will look at taking things apart and putting them back together again, or just taking them apart to salvage components.

In today's throw-away society, many consumer electronics items that stop working go directly into the garbage. Economically, they are simply not worth paying someone to repair. However, that does not mean it is not worth *trying* to repair them. Even if the attempt fails, some serviceable components may be scavenged for use in your projects.

How to Avoid Electrocution

When working on something that is powered by household electricity, NEVER work on it when it is plugged into the outlet. I actually like to have the electrical plug for the appliance right in front of me, so that I know it is not plugged in. Household electricity kills many people every year. Take it seriously!

Some devices, such as switch mode power supplies, contain high-value capacitors that will hold their charge for hours after the device has been unplugged. These capacitors are simply biding their time, waiting for some unsuspecting fingers to complete the circuit.

Unless it is a very small capacitor, it should not be discharged by shorting the leads with a screwdriver. A large capacitor at high voltage can supply huge amounts of charge in a fraction of a second, melting the end of the screwdriver and flinging molten metal around. People have been blinded by capacitors exploding in this manner, so don't do it.

Figure 10-1 shows the safe way to discharge a capacitor.

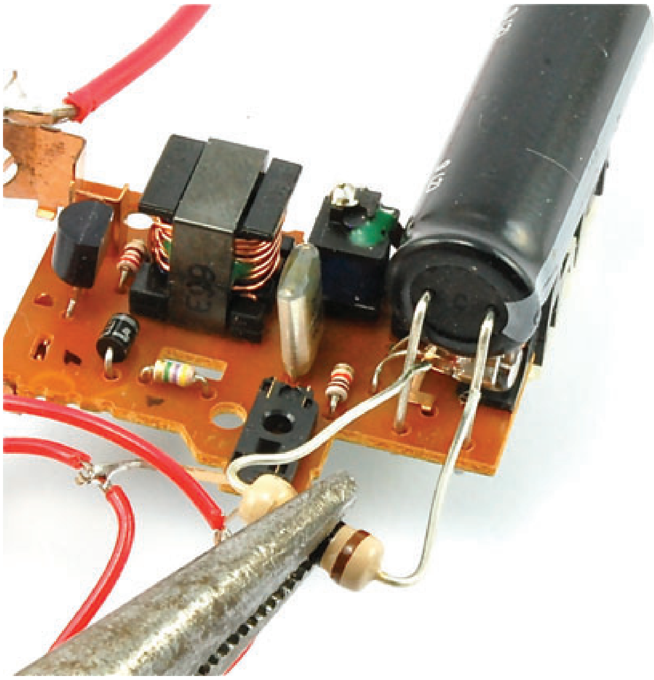

Figure 10-1 Safely discharging a capacitor

The legs of a 100Ω resistor are bent to the right fit for the capacitor contacts and held in the teeth of a pair of pliers for a few seconds. You can use the highest setting of your voltmeter to check that the capacitor has discharged to a safe level (say, 50V). If you have a high-wattage resistor, all the better. If it is not high enough power, it will break, but not in as spectacular a way as a capacitor being discharged dangerously.

Some devices that can pack a painful and sometimes lethal punch are:

- Old glass CRT TVs
- Switch-mode power supplies
- Camera flash guns and disposable cameras with a flash

How to Take Something Apart AND Put It Back Together Again

It is often said that “any fool can take something apart, but putting it back together is a totally different matter.”

Just remember that taking things apart usually voids their warranty.

By following a few simple rules, you shouldn't have any problems.

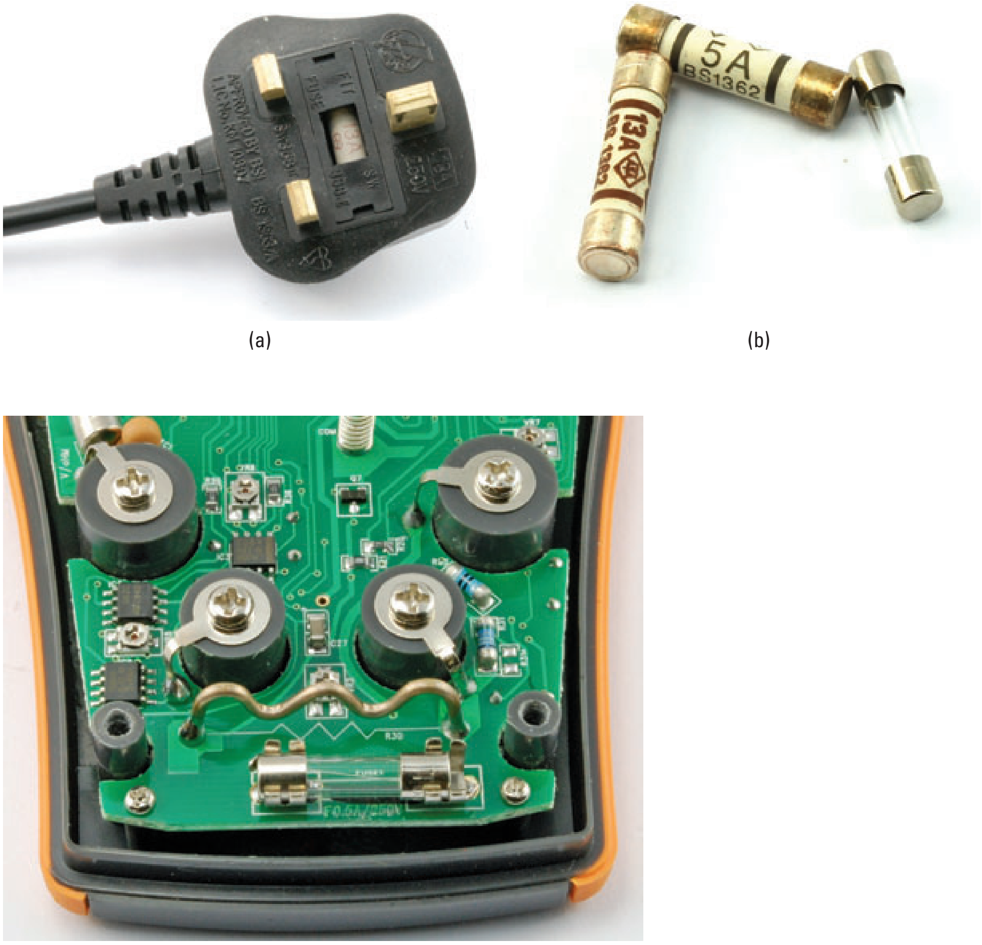
- Have a clear working area with lots of room.
- As you take out the screws, place them in the same pattern on your worktop as they were in the case they came out of. Sometimes the screws can be different sizes. If they are likely to be knocked or roll about on the surface, then push them into a piece of expanded polystyrene or something similar.
- After undoing the screws, when you come to take the case apart, watch out for any little plastic bits like switch buttons that might fall out. Try and keep them in place until you are ready to remove them.
- If something looks tricky, draw a sketch or take a photograph. (I tend to take a lot of photographs when repairing things, like with a hair dryer or straighteners, that have a large mechanical design component.)
- Try not to force things apart. Look to see where the clips are.
- If all else fails, try cutting the case apart with a handsaw (something your author has resorted to in the past), and then later glue the case back together.

How to Check a Fuse

The most convenient problem to fix in an appliance is the fuse. It's convenient because it is easy to test and easy to fix. Fuses are basically just wires designed to burn out when the current flowing through them gets too high. This prevents further damage to more expensive components, or can stop a fire from starting.

Sometimes fuses are clear, so you can see that the wire inside them has broken and that they have "blown." Fuses are rated in amps and will generally be labeled to show the maximum current in A or mA they can take. Fuses also come as "fast blow" and "slow blow." As you would expect, this determines how fast the fuses react to over-current.

Some household electrical plugs contain a fuse holder, and you can also find fuses on PCBs. Figures 10-2a-c show the



(a) (b)

(c)

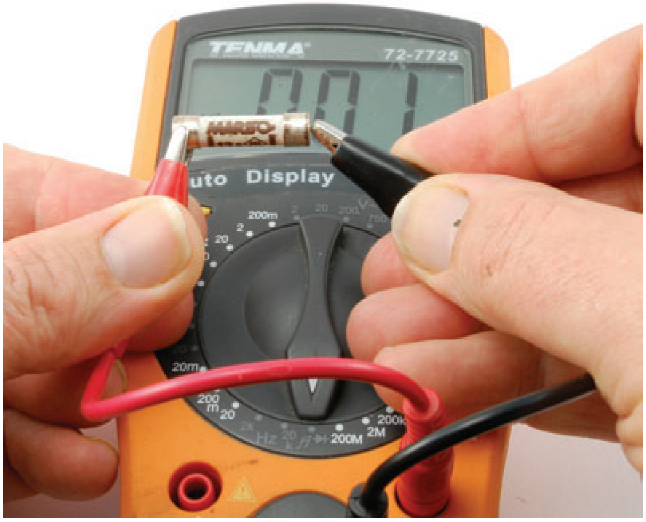
Figure 10-2 Fuses

inside of a UK fused plug and also a fuse holder on the PCB for the author's multimeter.

You have used your multimeter in Continuity mode enough times now that you can probably guess how to test a fuse (Figure 10-3).

If a fuse has blown, there may be a good reason for this. Occasionally, however, they blow for other reasons, such as a momentary spike in the electric power lines or when turning on a heating element on a particularly cold day. So, generally, if there is no obvious sign of a problem with the device

Figure 10-3 Testing a fuse with a multimeter



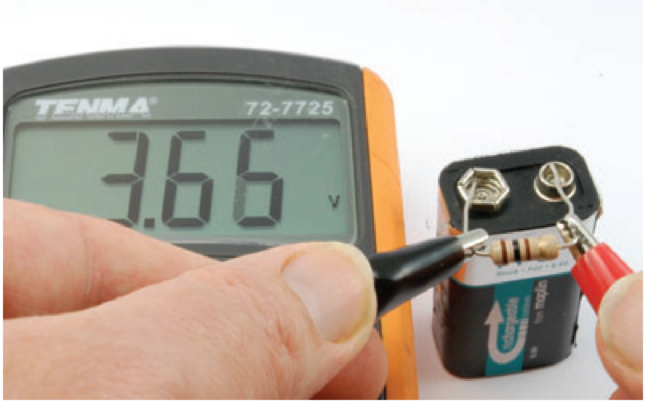
(look for wires that have come lose, or any sign of charring), then try replacing the fuse.

If the fuse immediately blows again, don't try another. You should instead find the source of the problem.

How to Test a Battery

Spent batteries are, of course, another common reason for something not working. Simply measuring the voltage will tell you very quickly if the battery is empty.

Figure 10-4 Testing a battery using a resistor and multimeter



During testing, if a 1.5V battery like an AA or AAA is showing less than 1.2V, or a 9V battery is showing less than 8V, it is probably time to throw it away. However, the voltage of a battery shown when it is not powering anything can be a little misleading. For a more accurate picture, use a 100Ω resistor as a "dummy" load. Figure 10-4 shows a resistor and multimeter being used to assess the state of the battery.

How to Test a Heating Element

If you have a suspect heating element from an oven, hair dryer, or so on, you can check it by measuring its resistance. As with anything using household electricity, only do this when the appliance is completely disconnected.

It's a good idea to roughly work out what you think the resistance should be before you measure it. So, for example, if you have a 2-kW 220V heating element, then rearrange:

$P = V^2 / R$

to

$R = V^2 / P = 220 \times 220 / 2000 = 24\Omega$

Calculating what you expect before you measure it is always a good idea, because if you measure it first, it is all too easy to convince yourself that it was what you were expecting. For instance, one time your humble author convinced himself that a suspect element was fine because it was showing a resistance of a few hundred ohms. Eventually, it transpired that there was a light bulb in parallel with the heating element and that the element itself was instead broken.

Finding and Replacing Failed Components

When something stops working on a PCB, it is often the result of something burning out. This sometimes leads to charring around the component. Resistors and transistors are common culprits.

Testing Components

Resistors are easy to test with a multimeter set to its resistance range. Although the results can be misleading, you can test them without removing them. Most of the time, you are looking for an open circuit, very high resistance, or sometimes a short (0Ω).

If your multimeter has a capacitance range, these too can easily be tested.

Other components are less easily identified. It is usually possible to make out some kind of device name on the case.

A magnifying glass is sometimes useful, as is taking a digital photograph and then zooming in to a high magnification. Having found some kind of identifying mark, type it into your favorite search engine.

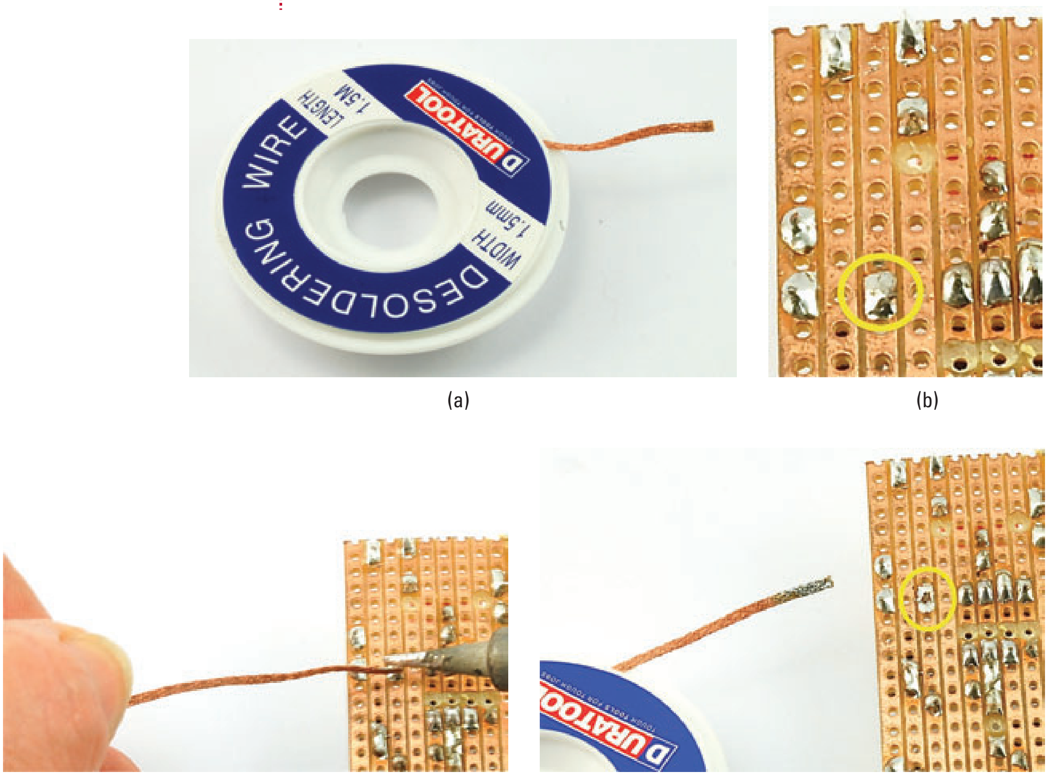
Bipolar transistors can also be tested (see the section “How to Use a Multimeter to Test a Transistor” in Chapter 11). However, if you have a spare, it is often easier just to replace it.

Desoldering

There is definitely a knack to desoldering. You often have to add more solder to get the solder to flow. I find it quite effective to draw the solder off onto the tip of the soldering iron, which I keep cleaning using the sponge.

Desoldering braid (Appendix – code T13) is also quite effective. Figure 10-5 shows the steps involved in using desoldering braid to remove the solder from around a component lead so it can be removed.

FIGURE 10-5 Using desoldering braid



(a) (b)

(c) (d)

Desoldering braid (Figure 10-5a) is supplied in small lengths on a small reel. You do not need much. It is braided wire impregnated with flux that encourages the solder to flow into it and off the PCB or stripboard copper.

Figure 10-5b shows the joint (circled in yellow) that we are going to remove the solder from. Press the braid onto the joint with the soldering iron (Figure 10-5c) and you should feel the blob of solder on the joint start to melt into the braid. Remove the braid while everything is hot and you should see a nice clean joint with the solder transferred to the braid (Figure 10-5d).

Cut off the section of the braid with solder on it and throw it away.

You may have to do this a couple of times to remove enough solder to release the component.

Replacement

Soldering in the replacement component is straightforward, you just have to make sure you get it the right way around. This is where photographing the board before making the replacement can be a good idea.

How to Scavenge Useful Components

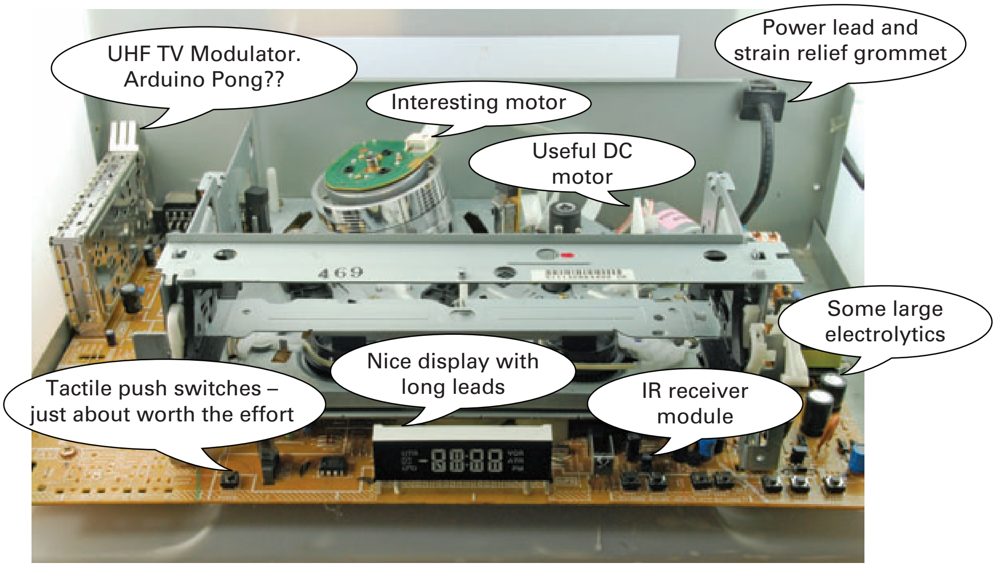
Dead consumer electronics are a good source of components. But be selective, because some components are really not worth saving. Resistors are so cheap that it is really not worth the effort of removing them.

Here is what I look for when scavenging:

- Any kind of motors
- Connectors
- Hookup wire
- Seven-segment LED displays
- Loudspeakers
- Switches
- Large transistors and diodes
- Large or unusual capacitors
- Screws nuts and bolts

FIGURE 10-6 Scavenging from a VCR

Figure 10-6 shows the insides of a dead video cassette recorder, with some of the more interesting parts for scavenging labeled.



UHF TV Modulator.
Arduino Pong??
Power lead and strain relief grommet
Interesting motor
Useful DC motor
Some large electrolytics
Nice display with long leads
Tactile push switches – just about worth the effort
IR receiver module

The easiest way to remove a lot of components, and things like hookup wire, is simply to snip them with wire cutters. The same applies to large electrolytic capacitors and other items, as long as they still leave leads long enough to use. Alternatively, you can desolder the items.

How to Reuse a Cell Phone Power Adapter

Everything you make in electronics requires a power source of some sort. Sometimes this will be batteries, but often it is more convenient to power the device from your household electricity.

Given that most of us have drawers stuffed with obsolete mobile phones and their charges, it makes sense to be able to reuse an old mobile phone charger. If they are newish phones, they may well have some kind of standard connector on them like a mini-USB or micro-USB, but many older phone models had a proprietary plug, used only by that phone manufacturer.

There is nothing to stop us from taking such an adapter and putting a more standard plug on the end of it, or even connecting the bare wires to screw terminals.

Figure 10-7 shows the steps involved in putting a different type of connector, such as a 2.1mm barrel jack, on the end of an old cell phone charger.

The charger is of the "wall-wart" type that plugs directly into an electrical outlet. The connector is of a type long since discontinued (Figure 10-7a). The charger has a label saying that it can supply 5V at 700mA, so the first step is (making sure the charger is unplugged) to chop off the existing connector and strip the bare wires. There should be two wires, and if one is black and one is red, then the red one is usually positive and the black negative. In this case, the wires are red and yellow. Whatever colors the wires are, it is always a good idea to use a multimeter to check the polarity (Figure 10-7b).

Remember to put the lead through the plastic body of the barrel jack before you start soldering!

You can then solder on a barrel jack plug (Appendix–code H11). This is much the same procedure we used for an audio lead in the section "Hacking Audio Leads" in Chapter 9. Figure 10-7c shows the plug ready to solder, while Figure 10-7d displays the final lead ready to use.

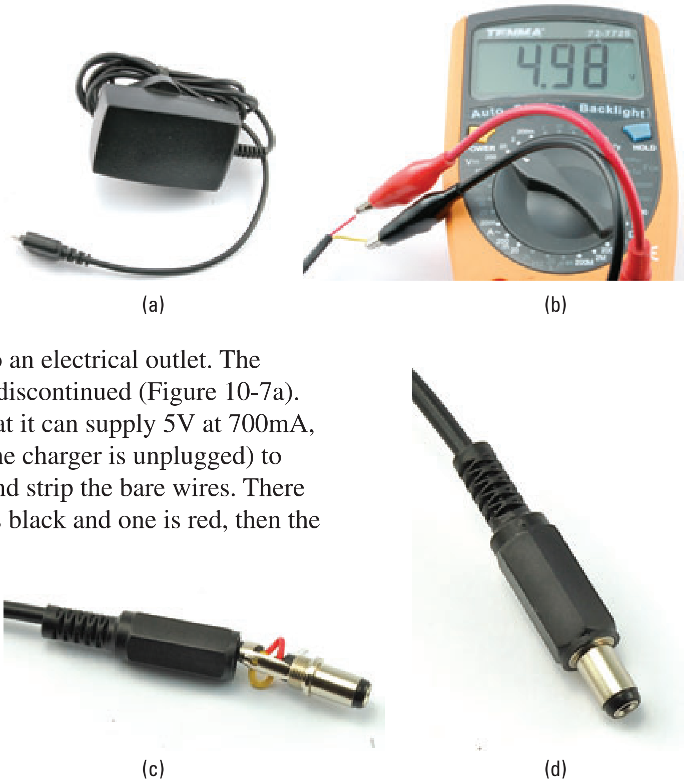


Figure 10-7 Attaching a barrel jack to a cell phone charger

Summary

In this chapter, we have discovered some of the treasures that can be rescued from dead electronic equipment and also briefly looked at testing and mending.

If you want to learn more about mending things, I recommend the book *How to Diagnose and Fix Everything Electronic* by Michael Geier (McGraw-Hill/TAB, 2011).

11

Tools

This chapter is mainly for reference. You have already met some of the techniques described here while working your way through the book.

How to Use a Multimeter (General)

Figure 11-1 shows a close-up of the range selector of my multimeter.

This is typical of a medium-range multimeter costing around USD 20. We have probably only used four or five of the settings during the course of this book, so it is worth pointing out some of the other features of a multimeter like this.

Continuity and Diode Test

Starting at 6 o'clock, we have the Continuity mode, represented by a little music symbol and also a diode symbol. We have used the Continuity mode many times. It just beeps when there is very low resistance between the leads.

The reason a diode symbol appears here is because this mode also doubles for testing diodes. With some multimeters, this feature will also work on LEDs, allowing you to measure the forward voltage.

Connect the anode of the diode (the end without a stripe in a normal diode, and with a longer lead on an LED) to the red test lead of the multimeter, and then the other end of the diode to the black lead. The meter will then tell you the forward voltage of the diode. So, expect to see about 0.5V for a normal diode and 1.7V to 2.5V for an LED. You will probably also find that the LED glows a little.

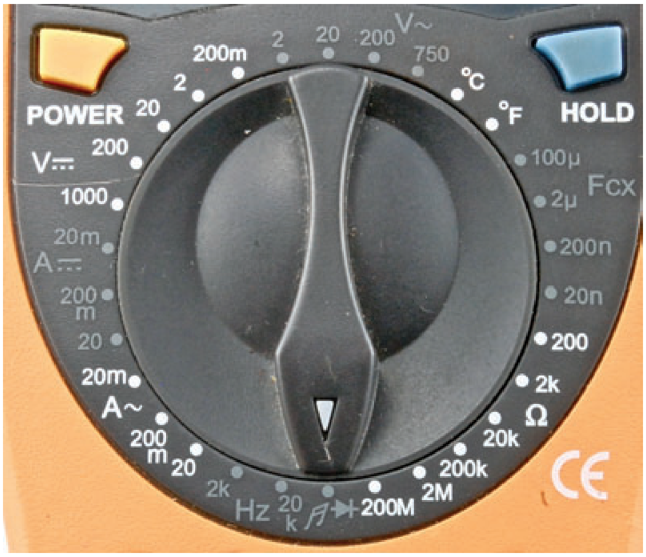

Figure 11-1 Multimeter range selection

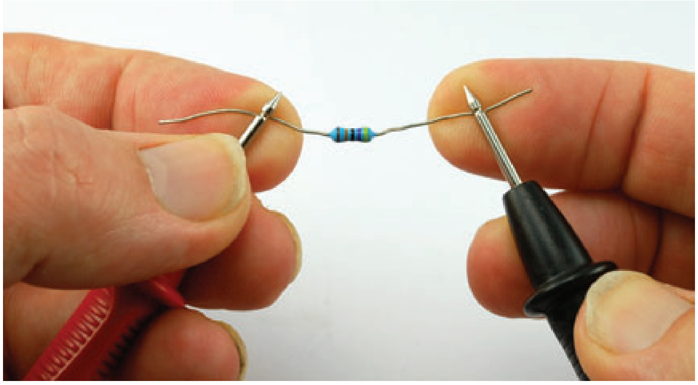
Resistance

The multimeter in Figure 11-1 has six resistance ranges, from 200MΩ down to 200Ω. If you pick a range that has a maximum resistance lower than the resistor you are measuring, then the meter will indicate this. Mine does so by displaying a "1" on its own without any further digits. This tells me I need to switch to a higher resistance range. Even better, start at the maximum range and work your way down until you get a precise reading. For the most precise reading, you need the meter to be on the range above the one that tells you it's out of range.

When measuring high-value resistors of 100kΩ and up, remember that you yourself are also a big resistor, so if you hold the test lead to the resistor at both ends (see Figure 11-2), you are measuring both the resistor in question and your own resistance.

Use test leads with crocodile clips, or pin the resistor to your work surface with the flat of the test leads.

Figure 11-2 How not to measure high-value resistors



Capacitance

Some multimeters include a capacitance range. While not particularly useful for finding the value of unknown capacitors (capacitors have their value written on them), being able to test a capacitor and make sure it still has a capacitance something close to its stated value is useful.

The capacitance range on most meters is quite inaccurate, but then the values of actual capacitors—especially electrolytics—often have quite a wide tolerance.

In other words, if your meter tells you that your 100μF capacitor is actually 120μF, then that is to be expected.

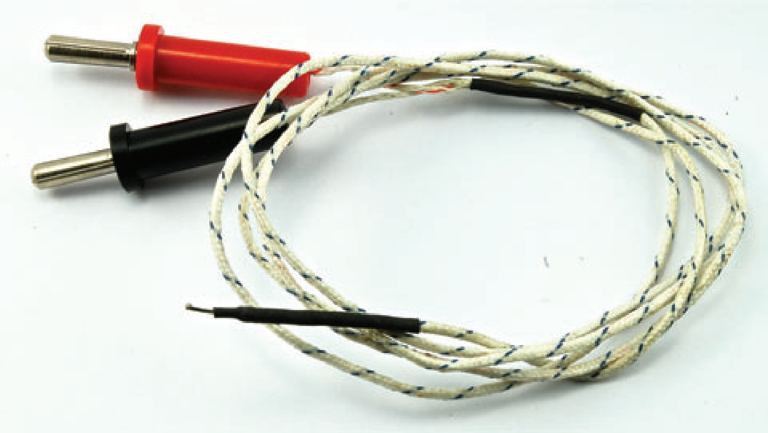
Temperature

If your multimeter has a temperature range, it probably also comes with a special set of leads for measuring it, such as those shown in Figure 11-3.

The leads are actually a thermocouple that can measure the temperature of the tiny metal bead on the end of the leads. This thermometer is a lot more useful than your average digital thermometer. Check the manual for your meter, but the range of temperature is likely to be something like –40°C to 1000°C (–40°F to 1832°F).

So, you can use it to check how hot your soldering iron is getting, or if you have a component in a project that seems to be getting a bit toasty, you can use this to check just how hot it is getting.

FIGURE 11-3 Thermocouple leads for temperature measurement



AC Voltage

We have not talked about AC very much in this book. AC stands for alternating current and refers to the type of electricity you get in a home wall socket's 110V or 220V supply. Figure 11-4 shows how 110V AC household electricity voltage varies over time.

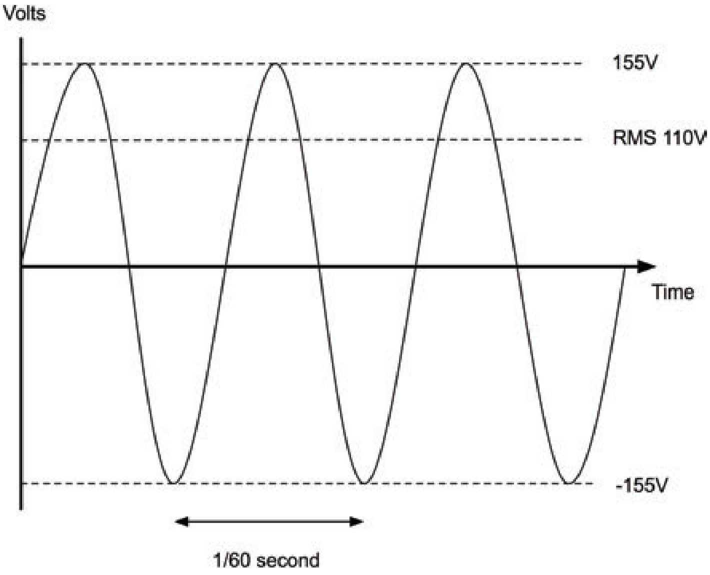
From Figure 11-4, it is apparent that the voltage actually reaches a peak of 155V and swings all the way negative to –155V. So you might be wondering why it is referred to as 110V at all.

The answer is that since a lot of the time, the voltage is quite low, at those times, it delivers very little power. So the 110V is a kind of average. It's not the normal average voltage, because that would be (110 – 110) / 2 = 0V, and because half the time it is negative.

110V is the RMS voltage (root mean squared). This is the peak positive voltage divided by the square root of 2 (1.4). You can think of this as the DC equivalent voltage. So a light bulb running on 110V AC would appear to be the same brightness as if it were running on 110V DC.

You are unlikely to need to measure AC unless you are doing something exotic and dangerous, and you should not do that unless you are very sure about what you are doing and therefore probably already knew what I just told you.

Figure 11-4 Alternating current



DC Voltage

We have already measured DC voltage quite a lot—mostly at the 0 to 20V range.

There is nothing much more to say about this, except to always start with the highest voltage range you believe you are about to measure and then work your way down.

DC Current

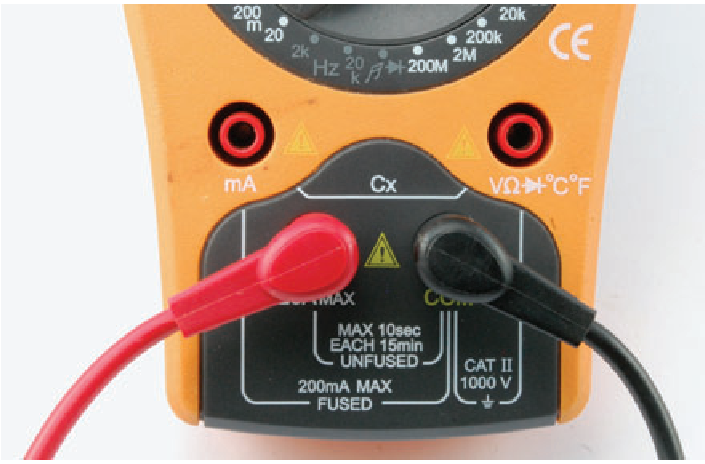
When measuring current, you will probably find that for all current ranges you will need to use different sockets on the multimeter for the positive probe lead. There is usually one connection for low currents and a separate one for the high-current ranges (20A on the author's multimeter; see Figure 11-5).

There are two important points to consider here. First, if you exceed the current range, your meter will not just give you a warning, it may well blow a fuse within the meter.

The second point is that when the probe leads are in the sockets for current measurement, there is a very low resistance between them. After all, they need to allow as much of the original current as possible to flow through them. So, if you forget that the leads are in these sockets and go to measure a voltage elsewhere in the circuit, you will effectively short-out your circuit and probably blow the fuse on your multimeter at the same time.

So, just to reiterate, if you have been using your multimeter to measure current, ALWAYS put the probe leads back to their

Figure 11-5 High-current measurement



voltage sockets, as these are more likely to be used next. If you try and measure current with the leads in the voltage sockets, then all that will happen is that you get a reading of zero.

AC Current

The same argument that we gave for measuring AC voltage probably applies here. Exercise extreme caution.

Frequency

If your multimeter has a frequency setting, this can be useful. For example, in the section "How to Generate Tones with a 555 Timer" in Chapter 9 where we create an audio tone using a 555 timer, you could use this feature to measure the frequency of the tone being produced. This can be handy if you do not have access to an oscilloscope.

How to Use a Multimeter to Test a Transistor

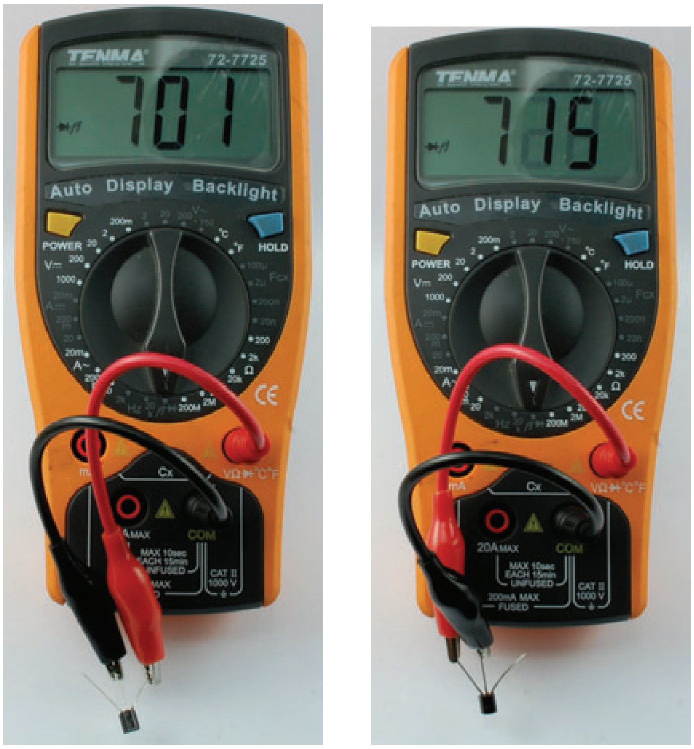
Some multimeters actually have a transistor test socket where you can plug in a transistor. The multimeter will not only tell you if the transistor is alive or dead, but also what its gain (Hfe) is.

If your multimeter does not have such a feature, you can use the diode test feature to at least tell you if the transistor is undamaged.

Figure 11-6 shows the steps involved in testing an NPN bipolar transistor like the 2N3906.

Put the multimeter into diode test mode and attach the negative lead of the meter to the center base connection of the transistor, and the positive lead to one of the other leads of the transistor. It does not matter if it is the emitter or collector (check the transistor's pinout to find the base). You should get a reading, somewhere between 500 and 900. This is the forward voltage in mA between the base and whichever other connection you chose (Figure 11-6a). Then, move the positive lead to the other lead of the transistor (Figure 11-6b) and you should see a similar figure. If either reading is zero, either your transistor is dead, or it is a PNP type of transistor, in which case you need to carry out the same procedure but with the positive and negative leads to the multimeter reversed.

FIGURE 11-6 Testing a transistor



(a) (b)

How to Use a Lab Power Supply

We came across a lab power supply back in Chapter 5. If you have your soldering equipment and a multimeter, then a lab power supply (Figure 11-7) is probably the next item to invest in. It will get a lot of use.

The power supply shown in Figure 11-7 is a simple-to-use basic design. In the figure, it is being used to charge a lead–acid battery. You will find that you use it to power your projects while developing them. You should be able to get something similar for under USD 100.

It plugs into your home electrical socket and can deliver up to 20V at 4A, which is more than enough for most purposes. The screen displays the voltage at the top, and the current being consumed at the bottom.

The reasons why it is more convenient than using batteries or a fixed power supply are:

- It displays how much current is being consumed.
- You can limit the current consumption.
- You can use it in constant current mode when testing LEDs.
- You can adjust the voltage easily.

The control panel has an Output switch that turns the output voltage on and off, and two knobs that control the voltage and current.

If I am powering up some project for the first time, I will often follow this procedure:

1. Set the current to its minimum setting.
2. Set the desired voltage.
3. Turn on the output (the voltage will probably drop).
4. Increase the current and watch the voltage rise, making sure that the current isn't rising to an unexpected level.

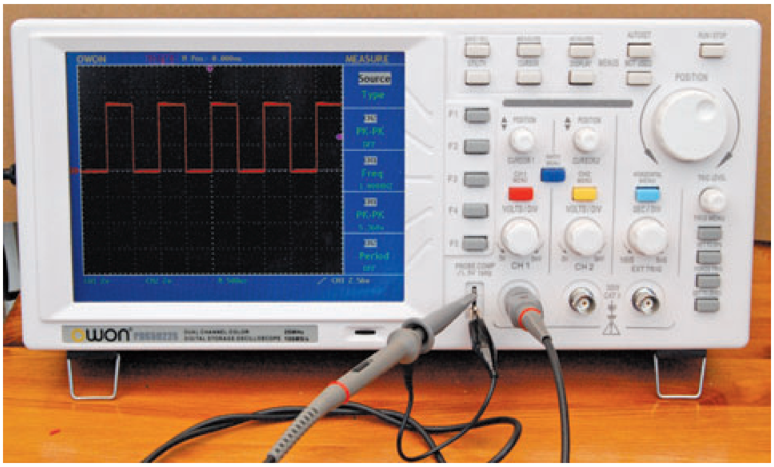
Introducing: The Oscilloscope

Oscilloscopes (Figure 11-8) are an indispensable tool for any kind of electronics design or test where you are looking at a signal that changes over time. They are a relatively expensive

FIGURE 11-8 A low-cost digital oscilloscope



OWON
MEASURE
Source
POSITION
CH 1
CH 2

bit of equipment (from USD 200 on up) and there are various kinds. One of the most cost-effective types does not have any display at all, but connects to your computer over USB. If you don't want to risk blobs of solder on your laptop, or wait for it to boot up, then a dedicated oscilloscope is probably best.

Entire books have been written about using an oscilloscope effectively, and every oscilloscope is different, so we will just cover the basics here.

As you can see from Figure 11-8, the waveform is displayed over the top of a grid. The vertical grid is in units of some fraction of volts, which on this screen is 2V per division. So the voltage of the square wave in total is 2.5 × 2 or 5V.

The horizontal axis is the time axis, and this is calibrated in seconds. In this case, 500 microseconds (µS) per division. So the length of one complete cycle of the wave is 1000 µS—or 1 millisecond—indicating a frequency of 1 KHz.

The other advantage of an oscilloscope is that the test leads are very high impedance, which means that they have very little effect on the thing you are trying to measure.

Software Tools

As well as hardware tools for hacking electronics, there are lots of useful software tools that can help us out.

Simulation

If you like the idea of trying out electronic designs in a virtual world, you should try one of the online simulators like CircuitLab (www.circuitlab.com). This online tool (Figure 11-9) allows you to draw your circuits online and simulate how they will behave.

You will have to pick up a bit more theory than this book covers, but a tool like this can save you a lot of effort.

Fritzing

Fritzing (www.fritzing.org) is a really interesting open-source software project that lets you design projects. It is intended

primarily for breadboard design and includes libraries of components and modules, such as an Arduino, that can all be wired up (Figure 11-10).

EAGLE PCB

If you want to start creating your own PCBs for your electronics designs, then look for the most popular tool for this, which is called EAGLE PCB (Figure 11-11). It allows you to draw a schematic diagram and then switch to a PCB view where you can route the connections between components before creating the CAM (computer-aided manufacturing) files, which you can then send off to a PCB fabrication shop.

Creating PCBs is a subject in its own right. For more information on this, take a look at the book *Make Your Own PCBs with EAGLE: From Schematic Designs to Finished Boards* by Simon Monk (TAB, 2013).

Online Calculators

Online calculators can make your electronics math a whole lot easier. Some of the more useful ones are:

- **http://led.linear1.org/1led.wiz** A series resistor calculator for LEDs
- **http://led.linear1.org/led.wiz** Designed for driving large numbers of LEDs
- **www.bowdenshobbycircuits.info/555.htm** A 555 timer IC component calculator

Summary

This is the last chapter in this book and I hope it will help you get started "hacking electronics." There is much satisfaction in making something physical, or modifying a device so it does just what you want.

The line between producer and consumer is blurring more and more today as people start designing and building their own electronic devices.

The Internet offers many useful resources. The following web sites are worth a special mention:

- www.hacknmod.com
- www.instructables.com
- www.arduino.cc (for Arduino)
- www.sparkfun.com (modules and interesting components)
- www.adafruit.com (more cool stuff)
- www.dealextreme.com (bargains; search for LEDs, etc.)
- www.ebay.com (search for the same items as that in the other URLs in this list)

See also the components suppliers mentioned in the Appendix.

Appendix

Parts

Prices of components vary enormously, so please treat the following lists as a guide and shop around.

I know some people who buy almost everything on eBay. But beware. Though things are often very cheap there, occasionally they are much more expensive than at other suppliers.

I have listed part codes for the tools, modules, and so on from SparkFun and Adafruit, as these suppliers are very accessible to hobbyists and also provide good accompanying documentation. They also have distributors throughout the world, so you do not have to buy direct from either company if you live outside the U.S.

For other components, I have tried to list product codes for Mouser and DigiKey since these predominate as suppliers to hobbyists in the U.S., and also Farnell, who are UK-based but will ship to anywhere.

Please also see the book's web site (www.hackingelectronics.com) as updates for component availability will appear here.

Components

To get yourselves a basic stock of components, you are strongly recommended to buy a starter kit of components. SparkFun sells such a set, but it doesn't include resistors, so you will need to buy a resistor set, too. Once you have these, you will own a useful collection of components that should cover the majority of what you need.

Component Starter Kits

The SparkFun Beginner Parts Kit and Resistor Kit will give you a good initial stock of parts.

  construction of, 126, 229
  items needed for, 125, 229
  schematic diagrams, 126, 228
  software sketch, 126–127
toolkits, 3–5
tools, 3–5, 245–256
  EAGLE PCB, 254, 255
  fritzing, 253–254, 255
  lab power supply, 251–252
  multimeter, 245–251
  online calculators, 256
  oscilloscope, 252–253
  part codes for, 257–258
  simulation, 253, 254
  software, 253–256
toy hacking projects
  Arduino-controlled toy, 116–119
  web-controlled toy, 128–136
transistors, 24
  bipolar, 39–40, 45–47
  commonly used, 47
  datasheets for, 45–46
  MOSFET, 46, 163–166
  NPN, 39–40, 47
  PNP, 46–47
  testing, 250–251
trickle charging, 89, 90
  battery backup, 100–101
  solar panels for, 103–104
tweeters and woofers, 224
twisting wires together, 7–8

U

ultrasonic range finding, 154
ultrasonic rangefinder modules, 153–158
  general description of, 153–154
  HC-SR04 rangefinder, 155–157
  MaxBotix LV-EZ1 rangefinder, 157–158
ultraviolet LEDs, 60–61
USB music controller, 229–232
  construction of, 230
  software sketch, 230–232

V

valueOfParam function, 136
variable power supply, 91–92
variable resistors, 22
variable_led_brightness sketch, 124–125
variable_led_flash sketch, 123–124
VCR scavenging, 243
vibration detector, 202–204
  construction of, 202–203
  items needed for, 202
  software sketch, 203–204
voltage, 26–27
  Arduino for measuring, 119–121
  boosting from batteries, 97–98
  controlling from batteries, 95–97
  converting a resistance to, 37–38
  determining for LEDs, 66–67
  dividing with resistors, 34–36
  measuring with multimeters, 248–249
voltage dividers, 36, 119–121

voltage regulators, 95–97
  breadboard layout, 96
  common types of, 97
  sample schematic, 95
  See also constant current driver
voltmeter sketch, 120–121
VU meter, 232–234
  construction of, 233
  software sketch, 233–234

W

watts, 28
web resources, 256
  Arduino-related, 106, 128, 148, 256
  Hacking Electronics book, 71, 105, 257
  software tools, 253–256
web-controlled toy project, 128–136
  construction of, 130
  items needed for, 129
  network configuration, 131, 132
  software sketch, 132–136
  testing process, 131
  wiring diagram, 130
  See also electric toy project
wire
  desoldering, 241–242
  joining, 7–8, 11–12
  multi-core, 6
  part codes for, 257–258
  purchasing, 4
  screened, 6
  soldering, 11–12
  solid-core, 4, 5–6
  stripping, 5, 6–7
  twisting, 7–8
  types of, 5–6
wire snips, 6–7
wire strippers, 6
wireless remote modules, 159–162
  breadboard layout, 159–160
  items needed for, 159, 161
  software sketch, 161–162
  using with Arduino, 161–162
wiring diagrams
  fume extractor, 15
  light sensing push light, 44
  modified slot car, 81
  remote relay control, 130
  See also schematic diagrams
woofers and tweeters, 224

CONTENTS

Preface . . . . **xxv**

Editors . . . . **xxvii**

Part I. Mathematics **1**

M1. Arithmetic and Elementary Algebra **3**

M1.1. Real Numbers 3
  M1.1.1. Integer Numbers 3
  M1.1.2. Real, Rational, and Irrational Numbers 4

M1.2. Equalities and Inequalities. Arithmetic Operations. Absolute Value 5
  M1.2.1. Equalities and Inequalities 5
  M1.2.2. Addition and Multiplication of Numbers 5
  M1.2.3. Ratios and Proportions 6
  M1.2.4. Percentage 6
  M1.2.5. Absolute Value of a Number (Modulus of a Number) 7

M1.3. Powers and Logarithms 7
  M1.3.1. Powers and Roots 7
  M1.3.2. Logarithms 8

M1.4. Binomial Theorem and Related Formulas 9
  M1.4.1. Factorials. Binomial Coefficients. Binomial Theorem 9
  M1.4.2. Related Formulas 9

M1.5. Progressions 10
  M1.5.1. Arithmetic Progression 10
  M1.5.2. Geometric Progression 10

M1.6. Mean Values and Some Inequalities 11
  M1.6.1. Arithmetic Mean, Geometric Mean, and Other Mean Values 11
  M1.6.2. Inequalities for Mean Values 11
  M1.6.3. Some Inequalities of General Form 11

M1.7. Some Mathematical Methods 12
  M1.7.1. Proof by Contradiction 12
  M1.7.2. Mathematical Induction 12
  M1.7.3. Proof by Counterexample 13

Bibliography for Chapter M1 13

M2. Elementary Functions **15**

M2.1. Power, Exponential, and Logarithmic Functions 15
  M2.1.1. Power Function: $y = x^\alpha$ 15
  M2.1.2. Exponential Function: $y = a^x$ 17
  M2.1.3. Logarithmic Function: $y = \log_a x$ 18

M2.2. Trigonometric Functions 19
  M2.2.1. Trigonometric Circle. Definition of Trigonometric Functions 19
  M2.2.2. Graphs of Trigonometric Functions 21
  M2.2.3. Properties of Trigonometric Functions 22

M2.3. Inverse Trigonometric Functions 26
    M2.3.1. Definitions. Graphs of Inverse Trigonometric Functions 26
    M2.3.2. Properties of Inverse Trigonometric Functions 27

M2.4. Hyperbolic Functions 29
    M2.4.1. Definitions. Graphs of Hyperbolic Functions 29
    M2.4.2. Properties of Hyperbolic Functions 30

M2.5. Inverse Hyperbolic Functions 33
    M2.5.1. Definitions. Graphs of Inverse Hyperbolic Functions 33
    M2.5.2. Properties of Inverse Hyperbolic Functions 34

Bibliography for Chapter M2 35

M3. Elementary Geometry 37

M3.1. Plane Geometry 37
    M3.1.1. Triangles 37
    M3.1.2. Polygons 43
    M3.1.3. Circle 46

M3.2. Solid Geometry 49
    M3.2.1. Straight Lines, Planes, and Angles in Space 49
    M3.2.2. Polyhedra 51
    M3.2.3. Solids Formed by Revolution of Lines 55

Bibliography for Chapter M3 60

M4. Analytic Geometry 61

M4.1. Points, Segments, and Coordinate Plane 61
    M4.1.1. Cartesian and Polar Coordinates on Plane 61
    M4.1.2. Distance Between Points. Division of Segment in Given Ratio. Area of a Polygon 62

M4.2. Straight Lines and Points on Plane 64
    M4.2.1. Equations of Straight Lines on Plane 64
    M4.2.2. Mutual Arrangement of Points and Straight Lines 66

M4.3. Quadratic Curves 68
    M4.3.1. Circle 68
    M4.3.2. Ellipse 69
    M4.3.3. Hyperbola 71
    M4.3.4. Parabola 74
    M4.3.5. Transformation of Quadratic Curves to Canonical Form 75

M4.4. Coordinates, Vectors, Curves, and Surfaces in Space 78
    M4.4.1. Vectors and Their Properties 78
    M4.4.2. Coordinate Systems 79
    M4.4.3. Scalar, Cross, and Scalar Triple Products of Vectors 82

M4.5. Line and Plane in Space 84
    M4.5.1. Plane in Space 84
    M4.5.2. Line in Space 89
    M4.5.3. Mutual Arrangement of Points, Lines, and Planes 91

M4.6. Quadric Surfaces (Quadrics) 96
    M4.6.1. Quadrics and Their Canonical Equations 96
    M4.6.2. Quadrics (General Theory) 99

Bibliography for Chapter M4 102

M5. Algebra **103**

M5.1. Polynomials and Algebraic Equations 103
  M5.1.1. Polynomials and Their Properties 103
  M5.1.2. Linear and Quadratic Equations 105
  M5.1.3. Cubic Equations 105
  M5.1.4. Fourth-Degree Equation 107
  M5.1.5. Algebraic Equations of Arbitrary Degree and Their Properties 108

M5.2. Determinants and Matrices 112
  M5.2.1. Determinants 112
  M5.2.2. Matrices. Types of Matrices. Operations with Matrices 114
  M5.2.3. Inverse Matrix. Functions of Matrices 119
  M5.2.4. Eigenvalues and Characteristic Equation of a Matrix. The Cayley–Hamilton Theorem 120

M5.3. Systems of Linear Algebraic Equations 123
  M5.3.1. Consistency Condition for a Linear System 123
  M5.3.2. Finding Solutions of a System of Linear Equations 124

M5.4. Quadratic Forms 127
  M5.4.1. Quadratic Forms and Their Transformations 127
  M5.4.2. Canonical and Normal Representations of a Quadratic Form 129

M5.5. Linear Spaces 131
  M5.5.1. Concept of a Linear Space. Its Basis and Dimension 131
  M5.5.2. Subspaces of Linear Spaces 134
  M5.5.3. Coordinate Transformations Corresponding to Basis Transformations in a Linear Space 135
  M5.5.4. Euclidean Space 136

Bibliography for Chapter M5 138

M6. Limits and Derivatives **139**

M6.1. Basic Concepts of Mathematical Analysis 139
  M6.1.1. Number Sets. Functions of Real Variable 139
  M6.1.2. Limit of a Sequence 141
  M6.1.3. Limit of a Function. Asymptotes 144
  M6.1.4. Infinitely Small and Infinitely Large Functions 146
  M6.1.5. Continuous Functions. Discontinuities of the First and the Second Kind 147
  M6.1.6. Convex and Concave Functions 148
  M6.1.7. Convergence of Functions 149

M6.2. Differential Calculus for Functions of a Single Variable 150
  M6.2.1. Derivative and Differential: Their Geometrical and Physical Meaning 150
  M6.2.2. Table of Derivatives and Differentiation Rules 151
  M6.2.3. Theorems about Differentiable Functions. L’Hospital Rule 153
  M6.2.4. Higher-Order Derivatives and Differentials. Taylor’s Formula 154
  M6.2.5. Extremal Points. Points of Inflection 156
  M6.2.6. Qualitative Analysis of Functions and Construction of Graphs 158
  M6.2.7. Approximate Solution of Equations (Root-Finding Algorithms for Continuous Functions) 160

M6.3. Functions of Several Variables. Partial Derivatives 162
  M6.3.1. Point Sets. Functions. Limits and Continuity 162
  M6.3.2. Differentiation of Functions of Several Variables 163
  M6.3.3. Directional Derivative. Gradient. Geometrical Applications 166
  M6.3.4. Extremal Points of Functions of Several Variables 167
  M6.3.5. Differential Operators of the Field Theory 170

Bibliography for Chapter M6 170

M7. Integrals **171**

M7.1. Indefinite Integral 171
  M7.1.1. Antiderivative. Indefinite Integral and Its Properties 171
  M7.1.2. Table of Basic Integrals. Properties of the Indefinite Integral. Examples of Integration 172
  M7.1.3. Integration of Rational Functions 174
  M7.1.4. Integration of Irrational Functions 177
  M7.1.5. Integration of Exponential and Trigonometric Functions 179
  M7.1.6. Integration of Polynomials Multiplied by Elementary Functions . . . 181

M7.2. Definite Integral 183
  M7.2.1. Basic Definitions. Classes of Integrable Functions. Geometrical Meaning of the Definite Integral 183
  M7.2.2. Properties of Definite Integrals and Useful Formulas 184
  M7.2.3. Asymptotic Formulas for the Calculation of Integrals 185
  M7.2.4. Mean Value Theorems. Properties of Integrals in Terms of Inequalities 187
  M7.2.5. Geometric and Physical Applications of the Definite Integral 188
  M7.2.6. Improper Integrals with Infinite Integration Limits 190
  M7.2.7. Improper Integrals of Unbounded Functions 193
  M7.2.8. Approximate (Numerical) Methods for Computation of Definite Integrals 194

M7.3. Double and Triple Integrals 195
  M7.3.1. Definition and Properties of the Double Integral 195
  M7.3.2. Computation of the Double Integral 197
  M7.3.3. Geometric and Physical Applications of the Double Integral 199
  M7.3.4. Definition and Properties of the Triple Integral 200
  M7.3.5. Computation of the Triple Integral. Some Applications. Iterated Integrals and Asymptotic Formulas 201

M7.4. Line and Surface Integrals 203
  M7.4.1. Line Integral of the First Kind 203
  M7.4.2. Line Integral of the Second Kind 205
  M7.4.3. Surface Integral of the First Kind 206
  M7.4.4. Surface Integral of the Second Kind 207
  M7.4.5. Integral Formulas of Vector Calculus 208

Bibliography for Chapter M7 209

M8. Series **211**

M8.1. Numerical Series and Infinite Products 211
  M8.1.1. Convergent Numerical Series and Their Properties. Cauchy's Criterion 211
  M8.1.2. Convergence Criteria for Series with Positive (Nonnegative) Terms 212
  M8.1.3. Convergence Criteria for Arbitrary Numerical Series. Absolute and Conditional Convergence 213

M8.1.4. Multiplication of Series. Some Inequalities 215

M8.2. Function Series 215
M8.2.1. Pointwise and Uniform Convergence of Function Series 215
M8.2.2. Basic Criteria of Uniform Convergence. Properties of Uniformly Convergent Series 216

M8.3. Power Series 218
M8.3.1. Radius of Convergence of Power Series. Properties of Power Series 218
M8.3.2. Taylor and Maclaurin Power Series 220
M8.3.3. Operations with Power Series. Summation Formulas for Power Series 221

M8.4. Fourier Series 223
M8.4.1. Representation of 2π-Periodic Functions by Fourier Series. Main Results 223
M8.4.2. Fourier Expansions of Periodic, Nonperiodic, Even, and Odd Functions 225
M8.4.3. Criteria of Uniform and Mean-Square Convergence of Fourier Series 226

Bibliography for Chapter M8 227

M9. Functions of Complex Variable **229**

M9.1. Complex Numbers 229
M9.1.1. Definition of a Complex Number. Arithmetic Operations with Complex Numbers 229
M9.1.2. Trigonometric Form of Complex Numbers. Powers and Radicals .. 230

M9.2. Functions of Complex Variables 231
M9.2.1. Basic Concepts. Differentiation of a Function of a Complex Variable 231
M9.2.2. Integration of Functions of Complex Variables 238
M9.2.3. Taylor and Laurent Series 241
M9.2.4. Zeros and Isolated Singularities of Analytic Functions 243
M9.2.5. Residues. Calculation of Definite Integrals 245

Bibliography for Chapter M9 249

M10. Integral Transforms **251**

M10.1. General Form of Integral Transforms. Inversion Formulas 251

M10.2. Laplace Transform 251
M10.2.1. Laplace Transform and the Inverse Laplace Transform 251
M10.2.2. Main Properties of the Laplace Transform. Inversion Formulas for Some Functions 252
M10.2.3. Limit Theorems. Representation of Inverse Transforms as Convergent Series 255

M10.3. Various Forms of the Fourier Transform 255
M10.3.1. Fourier Transform and the Inverse Fourier Transform 255
M10.3.2. Fourier Cosine and Sine Transforms 257

M10.4. Mellin Transform and Other Transforms 258
M10.4.1. Mellin Transform and the Inversion Formula 258
M10.4.2. Main Properties of the Mellin Transform. Relation Among the Mellin, Laplace, and Fourier Transforms 259
M10.4.3. Summary Table of Integral Transforms 259

Bibliography for Chapter M10 260

M11. Ordinary Differential Equations **261**

M11.1. First-Order Differential Equations 261
  M11.1.1. General Concepts. The Cauchy Problem. Uniqueness and Existence Theorems 261
  M11.1.2. Equations Solved for the Derivative. Simplest Techniques of Integration 263
  M11.1.3. Exact Differential Equations. Integrating Factor 265
  M11.1.4. Riccati Equation 267
  M11.1.5. Equations Not Solved for the Derivative 268
  M11.1.6. Approximate Analytic Methods for Solution of Equations 269
  M11.1.7. Numerical Integration of Differential Equations 270

M11.2. Second-Order Linear Differential Equations 271
  M11.2.1. Formulas for the General Solution. Some Transformations 271
  M11.2.2. Representation of Solutions as a Series in the Independent Variable 274
  M11.2.3. Boundary Value Problems 276
  M11.2.4. Eigenvalue Problems 277

M11.3. Second-Order Nonlinear Differential Equations 281
  M11.3.1. Form of the General Solution. Cauchy Problem 281
  M11.3.2. Equations Admitting Reduction of Order 281
  M11.3.3. Methods of Regular Series Expansions with Respect to the Independent Variable 283
  M11.3.4. Perturbation Methods in Problems with a Small Parameter 284
  M11.3.5. Galerkin Method and Its Modifications (Projection Methods) 287
  M11.3.6. Iteration and Numerical Methods 291

M11.4. Linear Equations of Arbitrary Order and Linear Systems of Equations 292
  M11.4.1. Linear Equations with Constant Coefficients 292
  M11.4.2. Linear Equations with Variable Coefficients 296
  M11.4.3. Systems of Linear Equations with Constant Coefficients 298

M11.5. Nonlinear Equations of Arbitrary Order 301
  M11.5.1. Structure of the General Solution. Cauchy Problem 301
  M11.5.2. Equations Admitting Reduction of Order 302

Bibliography for Chapter M11 303

M12. Partial Differential Equations **305**

M12.1. First-Order Quasilinear Partial Differential Equations 305
  M12.1.1. Characteristic System. General Solution 305
  M12.1.2. Cauchy Problem 306

M12.2. Classification of Second-Order Linear Partial Differential Equations 307
  M12.2.1. Equations with Two Independent Variables 307
  M12.2.2. Equations with Many Independent Variables 310

M12.3. Basic Problems for Linear Equations of Mathematical Physics 311
  M12.3.1. Initial and Boundary Conditions. Cauchy Problem. Boundary Value Problems 311
  M12.3.2. First, Second, Third, and Mixed Boundary Value Problems 313

M12.4. Properties and Exact Solutions of Linear Equations 314
  M12.4.1. Homogeneous Linear Equations and Their Particular Solutions . . 314
  M12.4.2. Nonhomogeneous Linear Equations and Their Particular Solutions 319

M12.5. Method of Separation of Variables (Fourier Method) 320
  M12.5.1. Solution of Problems for Parabolic Equations 320
  M12.5.2. Solution of Problems for Hyperbolic Equations 324
  M12.5.3. Solution of Problems for Elliptic Equations 326

M12.6. Integral Transforms Method 328
  M12.6.1. Laplace Transform and Its Application to Linear Mathematical Physics Equations 328
  M12.6.2. Fourier Transform and Its Application for Linear Equations of Mathematical Physics 331

M12.7. Boundary Value Problems for Parabolic Equations with One Space Variable. Green's Function 332
  M12.7.1. Representation of Solutions via the Green's Function 332
  M12.7.2. Problems for Parabolic Equation $\rho(x)\frac{\partial w}{\partial t} = \frac{\partial}{\partial x}\left[p(x)\frac{\partial w}{\partial x}\right] - q(x)w + \Phi(x,t)$ 334

M12.8. Boundary Value Problems for Hyperbolic Equations with One Space Variable. Green's Function. Goursat Problem 336
  M12.8.1. Representation of Solutions in terms of the Green's Function 336
  M12.8.2. Problems for Hyperbolic Equation $\rho(x)\frac{\partial^2 w}{\partial t^2} = \frac{\partial}{\partial x}\left[p(x)\frac{\partial w}{\partial x}\right] - q(x)w + \Phi(x,t)$ 338
  M12.8.3. Goursat Problem (a Problem with Initial Data of Characteristics) 340

M12.9. Boundary Value Problems for Elliptic Equations with Two Space Variables 342
  M12.9.1. Problems and the Green's Functions for Equation $a(x)\frac{\partial^2 w}{\partial x^2} + \frac{\partial^2 w}{\partial y^2} + b(x)\frac{\partial w}{\partial x} + c(x)w = -\Phi(x,y)$ 342
  M12.9.2. Representation of Solutions to Boundary Value Problems via the Green's Functions 343
  M12.9.3. Solutions of Problems for the Laplace Equation in the Polar Coordinate System 344

M12.10. Problems with Many Space Variables. Representation of Solutions via Green's Functions 345
  M12.10.1. Boundary Value Problems for Parabolic Equations 345
  M12.10.2. Boundary Value Problems for Hyperbolic Equations 347
  M12.10.3. Boundary Value Problems for Elliptic Equations 348
  M12.10.4. Construction of the Green's Functions. General Formulas and Relations 348

M12.11. Duhamel's Principles in Nonstationary Problems 349
  M12.11.1. Problems for Homogeneous Linear Equations 349
  M12.11.2. Problems for Nonhomogeneous Linear Equations 351

Bibliography for Chapter M12 352

M13. Special Functions and Their Properties 355

M13.1. Some Coefficients, Symbols, and Numbers 355
  M13.1.1. Factorials. Binomial Coefficients. Pochhammer Symbol 355
  M13.1.2. Bernoulli Numbers 356

M13.2. Error Functions. Exponential and Logarithmic Integrals 356
  M13.2.1. Error Function and Complementary Error Function 356
  M13.2.2. Exponential Integral 357
  M13.2.3. Logarithmic Integral 357

M13.3. Sine Integral and Cosine Integral. Fresnel Integrals 358
  M13.3.1. Sine Integral 358
  M13.3.2. Cosine Integral 358
  M13.3.3. Fresnel Integrals 359

M13.4. Gamma Function, Psi Function, and Beta Function 359
  M13.4.1. Gamma Function 359
  M13.4.2. Psi Function (Digamma Function) 360
  M13.4.3. Beta Function 361

M13.5. Incomplete Gamma Function 361
  M13.5.1. Integral Representations. Recurrence Formulas 361
  M13.5.2. Expansions as $x \to 0$ and $x \to \infty$. Relation to Other Functions 362

M13.6. Bessel Functions (Cylinder Functions) 362
  M13.6.1. Definitions and Basic Formulas 362
  M13.6.2. Integral Representations and Asymptotic Expansions 364

M13.7. Modified Bessel Functions 365
  M13.7.1. Definitions. Basic Formulas 365
  M13.7.2. Integral Representations and Asymptotic Expansions 366

M13.8. Degenerate Hypergeometric Functions (Kummer Functions) 367
  M13.8.1. Definitions and Basic Formulas 367
  M13.8.2. Integral Representations and Asymptotic Expansions 370

M13.9. Elliptic Integrals 370
  M13.9.1. Complete Elliptic Integrals 370
  M13.9.2. Incomplete Elliptic Integrals 372

M13.10. Orthogonal Polynomials 373
  M13.10.1. Legendre Polynomials and Legendre Functions 373
  M13.10.2. Laguerre Polynomials and Generalized Laguerre Polynomials . 375
  M13.10.3. Chebyshev Polynomials 376
  M13.10.4. Hermite Polynomials 377

Bibliography for Chapter M13 378

M14. Probability Theory 379

M14.1. Basic Concepts and Simplest Probabilistic Models 379
  M14.1.1. Rules and Formulas of Combinatorics 379
  M14.1.2. Probabilities of Random Events 380
  M14.1.3. Conditional Probability. Total Probability Formula 382
  M14.1.4. Sequence of Trials 384

M14.2. Random Variables and Their Characteristics 386
  M14.2.1. One-Dimensional Random Variables 386
  M14.2.2. Expectation, Variance and Moments of a Random Variable 388
  M14.2.3. Main Discrete Distributions and Their Numerical Characteristics 390
  M14.2.4. Main Continuous Distributions and Their Numerical Characteristics 393
  M14.2.5. Two-dimensional and Multivariate Random Variables 396

M14.3. Limit Theorems 399
  M14.3.1. Convergence of Random Variables 399
  M14.3.2. Limit Theorems 400

Bibliography for Chapter M14 402

Part II. Physics **403**

P1. Physical Foundations of Mechanics **405**

P1.1. Kinematics of a Point 405
  P1.1.1. Basic Definitions. Velocity and Acceleration 405
  P1.1.2. The Direct and Inverse Problems of Kinematics 406
  P1.1.3. Circular Motion 407
  P1.1.4. Relativity of Motion. Addition of Velocities 407

P1.2. Kinematics of a Rigid Body 408
  P1.2.1. Translational and Rotational Motion. Plane Motion 408
  P1.2.2. Instantaneous Axis of Rotation. Addition of Angular Velocities. Motion Relative to a Rotational Frame 408

P1.3. Dynamics 410
  P1.3.1. Newton's First Law. Mass. Momentum. Force 410
  P1.3.2. Newton's Second and Third Laws 411
  P1.3.3. Action at a Distance. Causality. Natural Forces 411
  P1.3.4. Galilean Relativity Principle 412

P1.4. Law of Conservation of Momentum 413
  P1.4.1. Center of Mass. Momentum of a System of Particles 413
  P1.4.2. Law of Conservation of Momentum. Motion of Center of Mass 414

P1.5. Law of Conservation of Energy 415
  P1.5.1. Work and Power. Kinetic Energy 415
  P1.5.2. Conservative Forces. Potential Energy 416
  P1.5.3. Mechanical Energy of a System of Particles. Law of Conservation of Mechanical Energy 418
  P1.5.4. Potential Curves. Stability 419

P1.6. Law of Conservation of Angular Momentum 420
  P1.6.1. Moment of Force. Net Force 420
  P1.6.2. Angular Momentum of a Particle. Motion in Central Field 421
  P1.6.3. Conservation of Angular Momentum for a System of Particles 423
  P1.6.4. Two-Body Problem. Reduced Mass 424

P1.7. Gravitational Field 425
  P1.7.1. Law of Universal Gravitation. Superposition Principle 425
  P1.7.2. Strength and Potential of Gravitational Field 426
  P1.7.3. Motion in a Central Field of Gravity. Kepler's Laws. Orbital and Escape Velocities 427

P1.8. Non-Inertial Reference Frames 427
  P1.8.1. Definition of Fictitious Forces 427
  P1.8.2. Translationally Moving Non-Inertial Frames 428
  P1.8.3. Uniformly Rotating Reference Frame 428

P1.9. Dynamics of Rigid Body 429
  P1.9.1. Rotation About a Fixed Axis 429
  P1.9.2. Properties of Moment of Inertia 430
  P1.9.3. Plane Motion of a Rigid Body 431
  P1.9.4. Motion with a Fixed Point 432

P1.10. Special Theory of Relativity 434
  P1.10.1. Basics of the Special Theory of Relativity 434
  P1.10.2. Consequences of the Lorentz Transformations. STR Kinematics . . 435
  P1.10.3. STR Dynamics 437

Bibliography for Chapter P1 439

P2. Molecular Physics and Thermodynamics **441**

P2.1. Basic Principles and Definitions 441
  P2.1.1. Two Approaches to Studying Matter 441
  P2.1.2. Equation of State 441

P2.2. First Law of Thermodynamics 443
  P2.2.1. Quantity of Heat. Internal Energy 443
  P2.2.2. First Law of Thermodynamics 443
  P2.2.3. First Law of Thermodynamics for an Ideal Gas 445

P2.3. Second Law of Thermodynamics 446
  P2.3.1. Formulations 446
  P2.3.2. Carnot's Theorem 446
  P2.3.3. Calculation of the Internal Energy 447

P2.4. Entropy 448
  P2.4.1. Clausius Inequality 448
  P2.4.2. Definition of Entropy 449
  P2.4.3. Direction of Non-Equilibrium Processes in a Thermally Insulated System 449
  P2.4.4. Statistical Meaning of Entropy 450
  P2.4.5. Third Law of Thermodynamics 451
  P2.4.6. Thermodynamic Potentials 451

P2.5. Kinetic Theory of Ideal Gases 453
  P2.5.1. The Basic Equation of the Kinetic Theory 453
  P2.5.2. Temperature and Energy of an Ideal Gas 454
  P2.5.3. Maxwell's Distribution 456
  P2.5.4. Boltzmann's Distribution 457

P2.6. Real Gases. Van Der Waals Equation 458
  P2.6.1. Isotherms of a Real Gas 458
  P2.6.2. Van Der Waals Equation 459

P2.7. Phase Equilibrium. Phase Transitions 461
  P2.7.1. Conditions for Phase Equilibrium 461
  P2.7.2. First-Order Phase Transitions 462

P2.8. Surface Tension 462
  P2.8.1. Surface Energy 462
  P2.8.2. Additional Pressure Under a Curved Surface 463
  P2.8.3. Wetting. Capillary Effects 464

P2.9. Transfer Phenomena in Gases 464
  P2.9.1. Collision of Molecules in a Gas 464
  P2.9.2. Qualitative Model of Transfer Phenomena in Gases 465

Bibliography for Chapter P2 467

P3. Electrodynamics **469**

P3.1. Electric Charge. Coulomb's Law 469
  P3.1.1. Electric Charge and Its Properties 469
  P3.1.2. Coulomb's Law 470

P3.2. Electric Field. Strength and Potential 470
  P3.2.1. Strength of Electric Field 470
  P3.2.2. Potential of an Electrostatic Field 472

P3.3. Gauss's Theorem 474
  P3.3.1. Statement of the Theorem 474
  P3.3.2. Application of Gauss's Theorem 475

P3.4. Conductors and Capacitors 477
  P3.4.1. Electrostatics of Conductors 477
  P3.4.2. Capacitors 479

P3.5. Electrostatics of Dielectrics 481
  P3.5.1. Polarization of Dielectrics 481
  P3.5.2. Types of Dielectric and Polarization Mechanisms 484

P3.6. Energy of Electrostatic Field 485
  P3.6.1. Energy of a System of Charges 485
  P3.6.2. Energy of an Electrostatic Field 486

P3.7. Direct Current 488
  P3.7.1. Electric Current in a Circuit 488
  P3.7.2. Current in a Closed Circuit 490
  P3.7.3. Classical Free-Electron Theory of Metals 491

P3.8. Constant Magnetic Field 492
  P3.8.1. Lorentz Force and Ampère Force 492
  P3.8.2. Calculation of Magnetic Induction 494
  P3.8.3. Ampère's Circuital Law and Flux of Magnetic Induction 496

P3.9. Magnetic Field in Matter 498
  P3.9.1. Magnetization. Molecular Currents 498
  P3.9.2. Types of Magnetic Materials and Magnetization Mechanisms 500

P3.10. Electromagnetic Induction 502
  P3.10.1. Faraday's Law of Electromagnetic Induction 502
  P3.10.2. Self-Induction and Mutual Induction 504
  P3.10.3. Energy of Magnetic Field 505

P3.11. Maxwell's Equations 506
  P3.11.1. Maxwell's Equations in Vacuum and Matter 506
  P3.11.2. Law of Conservation of Energy for Electromagnetic Fields 508
  P3.11.3. Relativistic Properties of Fields 509

Bibliography for Chapter P3 510

P4. Oscillations and Waves 511

P4.1. Oscillations 511
  P4.1.1. Harmonic Oscillations. Composition of Oscillations 511
  P4.1.2. Free Undamped Oscillations 513
  P4.1.3. Damped and Forced Oscillations 517

P4.2. Wave Processes 521
  P4.2.1. Elastic and Acoustic Waves 521
  P4.2.2. Electromagnetic Waves 528

Bibliography for Chapter P4 533

P5. Optics 535

P5.1. Geometric Optics. Radiometry 535
  P5.1.1. Geometric Optics 535
  P5.1.2. Radiometry and Photometry 537

P5.2. Wave Properties of Light 539
  P5.2.1. Interference of Light 539
  P5.2.2. Diffraction 545

P5.3. Interaction Between Light and Matter 551
  P5.3.1. Light Polarization. Fresnel Formulas 551
  P5.3.2. Light Dispersion and Absorption 555

P5.4. Foundations of Quantum Optics 558
  P5.4.1. Thermal Radiation 558
  P5.4.2. Light Quanta 562
  P5.4.3. Principle of Laser Operation 565

Bibliography for Chapter P5 568

P6. Quantum Mechanics. Atomic Physics 569

P6.1. Atomic Structure. Bohr Model 569
  P6.1.1. Nuclear Atomic Model 569
  P6.1.2. Bohr Model 570

P6.2. Elements of Quantum Mechanics 573
  P6.2.1. Wave Function. Uncertainty Relation 573
  P6.2.2. The Schrödinger Equation 574
  P6.2.3. Operator Approach in Quantum Mechanics 578
  P6.2.4. Motion in a Central Field. Hydrogen Atom 580
  P6.2.5. Electron Spin and Fine Structure of the Spectrum 585

P6.3. Structure and Spectra of Complex Atoms 586
  P6.3.1. Pauli Exclusion Principle. Structure of Complex Atoms 586
  P6.3.2. Spectra of Complex Atoms 588

P6.4. Elements of Physics of Molecules 591
  P6.4.1. Classification of Levels of a Molecule 592
  P6.4.2. Electron Energy. Theory of Chemical Bond 593
  P6.4.3. Vibrational and Rotational Spectra 594

Bibliography for Chapter P6 596

P7. Quantum Theory of Crystals 597

P7.1. Quantum Statistical Distributions and Their Application 597
  P7.1.1. Elements of Quantum Statistics 597
  P7.1.2. Electron Gas in Metal 601
  P7.1.3. Heat Capacity of Crystal Lattice. Phonons 604

P7.2. Electrons in a Periodic Field. Energy Bands 608
  P7.2.1. Qualitative Theory of Energy Bands 609
  P7.2.2. Quantum Mechanical Description of Energy Regions 611
  P7.2.3. Dynamics of Electron in Crystal 612
  P7.2.4. Band Theory of Semiconductors 614

Bibliography for Chapter P7 616

P8. Elements of Nuclear Physics 617

P8.1. Basic Properties of Nuclei 617
  P8.1.1. Characteristics of Nuclei 617
  P8.1.2. Nuclear Forces 621
  P8.1.3. Nuclear Models 623

P8.2. Nuclear Transformations . . . 625
P8.2.1. Radioactivity . . . 625
P8.2.2. Nuclear Reactions . . . 632
P8.3. Nuclear Power Engineering . . . 637
P8.3.1. Nuclear Fission . . . 637
P8.3.2. Fusion Reactions . . . 641
P8.4. Subatomic Particles . . . 642
P8.4.1. Classes of Subatomic Particles . . . 643
P8.4.2. Characteristics of Particles . . . 647
P8.4.3. Interaction Unification . . . 650
Bibliography for Chapter P8 . . . 651

Part III. Elements of Applied and Engineering Sciences 653

E1. Dimensions and Similarity . . . 655
E1.1. Dimensions . . . 655
E1.1.1. Basic and Derived Units of Measurement. Systems of Units of Measurement . . . 655
E1.1.2. Dimensional and Dimensionless Quantities. Dimensional Formula . . 655
E1.2. The π-Theorem and Its Practical Use . . . 656
E1.2.1. The π-Theorem . . . 656
E1.2.2. Simplest Examples of the Use of the π-Theorem . . . 659
E1.3. Similarity and Simulation. General Remarks . . . 664
E1.3.1. Similarity and Simulation . . . 664
E1.3.2. General Concluding Remarks . . . 665
Bibliography for Chapter E1 . . . 665

E2. Mechanics of Point Particles and Rigid Bodies . . . 667
E2.1. Kinematics . . . 667
E2.1.1. Kinematics of a Point . . . 667
E2.1.2. Kinematics of a Rigid Body . . . 671
E2.1.3. Plane-Parallel (Plane) Motion of a Rigid Body . . . 675
E2.1.4. Arbitrary Motion of a Rigid Body . . . 678
E2.1.5. Compound Motion of a Point . . . 681
E2.1.6. Compound Motion of a Body . . . 684
E2.2. Basic Notions and Laws of Mechanics . . . 687
E2.2.1. Basic Notions of Mechanics . . . 687
E2.2.2. Basic Laws of Mechanics . . . 689
E2.3. Statics . . . 690
E2.3.1. Basic Laws and Theorems of Statics . . . 690
E2.3.2. Balance Conditions for a System of Forces Applied to a Rigid Body 692
E2.3.3. Solution of the Problems of Statics . . . 693
E2.3.4. Center of Parallel Forces. Center of Gravity of a Rigid Body . . . 698
E2.3.5. Distributed Forces . . . 699
E2.3.6. Friction Laws (Coulomb Laws) . . . 700
E2.4. Dynamics of a Point Particle . . . 701
E2.4.1. Equations of Motion of a Point Particle . . . 701
E2.4.2. First and Second Problems of Dynamics . . . 702

E2.5. General Theorems of Dynamics of a Mechanical System 703
E2.5.1. Basic Notions and Definitions 703
E2.5.2. Theorem on the Motion of the Center of Mass 707
E2.5.3. Theorem on the Momentum 708
E2.5.4. Theorem on the Angular Momentum 710
E2.5.5. Theorem on the Kinetic Energy 712

E2.6. Elements of Analytical Mechanics 716
E2.6.1. D'Alembert's Principle 716
E2.6.2. Classification of Mechanical Constraints. Generalized Coordinates . 718
E2.6.3. Principle of Virtual Displacements 720
E2.6.4. General Equation of Dynamics (d'Alembert–Lagrange Principle) ... 722
E2.6.5. Lagrange Equations of the Second Kind 723

E2.7. Small Oscillations of Mechanical Systems 724
E2.7.1. Preliminaries 724
E2.7.2. Small Oscillations of a Conservative System 725
E2.7.3. Normal Coordinates 727
E2.7.4. Influence of Small Dissipative Forces on System Oscillations 728
E2.7.5. Forced Oscillations 729

E2.8. Dynamics of an Absolutely Rigid Body 730
E2.8.1. Rotation of a Rigid Body about a Fixed Axis 730
E2.8.2. Plane-Parallel (Plane) Motion of a Rigid Body 731
E2.8.3. Motion of a Rigid Body about a Fixed Point 732
E2.8.4. Elementary Theory of Gyroscope 737

E2.9. Elementary Theory of Impact 738

Bibliography for Chapter E2 743

E3. Elements of Strength of Materials 745

E3.1. Basic Notions 745
E3.1.1. Introduction. External and Internal Forces 745
E3.1.2. Stresses and Strains at a Point 746
E3.1.3. Basic Notions and Hypotheses 747

E3.2. Stress–Strain State at a Point 748
E3.2.1. Types of Stress State 748
E3.2.2. Uniaxial Tension and Compression 748
E3.2.3. Simple Shear 749

E3.3. Central Tension and Compression 750
E3.3.1. Longitudinal Force 750
E3.3.2. Stresses and Strains under Tension or Compression 751
E3.3.3. Strength Analysis under Tension and Compression 752

E3.4. Torsion 753
E3.4.1. Twisting Moment 753
E3.4.2. Stresses and Strains in Torsion 753
E3.4.3. Strength Analysis in Torsion 755

E3.5. Symmetrical Bending 755
E3.5.1. Bending Moment and Transverse Force 755
E3.5.2. Stresses and Strains under Symmetric Pure Bending 758
E3.5.3. Stresses and Strains in Symmetric Lateral Bending 760
E3.5.4. Strength Analysis in the Case of Symmetric Bending 761

E3.6. Combined Stress 763
  E3.6.1. Oblique Bending 763
  E3.6.2. Eccentric Extension or Compression 765
  E3.6.3. Bending with Torsion 766

E3.7. Stability of Compressed Rods 768
  E3.7.1. Critical Force 768
  E3.7.2. Euler Formula 768
  E3.7.3. Influence of Methods for Fixation of the Rod Ends on the Value of the Critical Force 770
  E3.7.4. Scope of the Euler Formula 770
  E3.7.5. Stability Analysis of Compressed Rods 771

Bibliography for Chapter E3 771

E4. Hydrodynamics **773**

E4.1. Hydrostatics 773
  E4.1.1. Properties of Incompressible Fluid at Rest. Basic Law of Hydrostatics 773
  E4.1.2. Force of Pressure on a Plane and on a Curved Wall 774
  E4.1.3. Archimedes Principle. Stability of Floating Bodies 777

E4.2. Hydrodynamic Equations and Boundary Conditions 778
  E4.2.1. Laminar Flows. Navier–Stokes Equations. Euler Equations 779
  E4.2.2. Initial Conditions and the Simplest Boundary Conditions 781
  E4.2.3. Turbulent Flows. Reynolds Equations 782

E4.3. Hydrodynamics of Thin Films 784
  E4.3.1. Preliminary Remarks. Different Regimes of Film Type Flow 784
  E4.3.2. Films on an Inclined Plane and on a Cylindrical Surface 785

E4.4. Fluid Flows in Tubes 786
  E4.4.1. Laminar Flows in Tubes of Various Cross-Sections 786
  E4.4.2. Turbulent Flows in Tubes 791

E4.5. Hydrodynamic Boundary Layers on a Flat Plate 796
  E4.5.1. Laminar Boundary Layer 796
  E4.5.2. Turbulent Boundary Layer 798

E4.6. Spherical Particles and Circular Cylinders in Translational Flow 800
  E4.6.1. Stokes Equations and Their Solution for the Axisymmetric Case 800
  E4.6.2. Spherical Particles in Translational Stokes Flow (at $\mathsf{Re} \to 0$) 802
  E4.6.3. Spherical Particles in Translational Flow in a Wide Range of Re 803
  E4.6.4. Translational Flow Past a Cylinder (the Plane Problem) 804

E4.7. Spherical Drops and Bubbles in Translational Flow 806
  E4.7.1. Spherical Drops and Bubbles in Translational Stokes Flow (at $\mathsf{Re} \to 0$) 806
  E4.7.2. Spherical Drops and Bubbles in Translational Flow at Various Reynolds Numbers 808

E4.8. Flow Past Nonspherical Particles 809
  E4.8.1. Translational Stokes Flow Past Ellipsoidal Particles 809
  E4.8.2. Translational Stokes Flow Past Bodies of Revolution 811
  E4.8.3. Translational Stokes Flow Past Particles of Arbitrary Shape 812
  E4.8.4. Sedimentation of Isotropic and Nonisotropic Particles 814
  E4.8.5. Flow Past Nonspherical Particles at Various Reynolds Numbers 815

E4.9. Motion of Several Particles. Effective Viscosity of Suspensions 816
E4.9.1. Motion of Two Spheres. Gravitational Sedimentation of Several Spheres 816
E4.9.2. Rate of Suspension Precipitation. Effective Viscosity of Suspensions 818

Bibliography for Chapter E4 819

E5. Mass and Heat Transfer 821

E5.1. Convective Mass and Heat Transfer. Equations and Boundary Conditions ... 821
E5.1.1. Mass and Heat Transfer in Laminar Flows 821
E5.1.2. Basic Dimensionless Parameters. Diffusion Fluxes and the Sherwood Number 824
E5.1.3. Mass and Heat Transfer in Turbulent Flows 825

E5.2. Mass Transfer in Liquid Films 826
E5.2.1. Mass Exchange Between Gases and Liquid Films 826
E5.2.2. Dissolution of a Plate by a Laminar Liquid Film 829

E5.3. Heat Transfer to a Flat Plate 831
E5.3.1. Heat Transfer in Laminar Flow 831
E5.3.2. Heat Transfer in Turbulent Flow 832

E5.4. Convective Heat and Mass Transfer in Tubes and Channels 834
E5.4.1. Heat and Mass Transfer in a Circular Tube with Constant Temperature of the Wall for Laminar Flows 834
E5.4.2. Heat and Mass Transfer in a Circular Tube with Constant Heat Flux at the Wall for Laminar Flows 838
E5.4.3. Heat and Mass Transfer in Plane Channels for Laminar Flows 839
E5.4.4. Turbulent Heat Transfer in Circular Tube and Plane Channel 841
E5.4.5. Limit Nusselt Numbers for Tubes of Various Cross-Sections 843

E5.5. Interior Heat Problems for Solid Bodies of Various Shapes 845
E5.5.1. Statement of the Problem 845
E5.5.2. Bulk Temperature for Bodies of Various Shapes 845

E5.6. Mass and Heat Exchange Between Particles of Various Shapes and a Quiescent Medium 847
E5.6.1. Stationary Mass and Heat Exchange 847
E5.6.2. Transient Mass and Heat Exchange 849

E5.7. Mass and Heat Transfer to a Spherical Particle in a Translational Flow 850
E5.7.1. Statement of the Problem 850
E5.7.2. Mass Transfer at Low Reynolds Numbers and Various Peclet Numbers 851
E5.7.3. Mass Transfer at Moderate and High Reynolds Numbers 852

E5.8. Mass and Heat Transfer to Spherical Drops and Bubbles in Translational Flow 853
E5.8.1. Statement of the Problem. Some Remarks 853
E5.8.2. Mass Transfer at Low Reynolds Numbers and Various Peclet Numbers 853
E5.8.3. Mass Transfer at Moderate and High Reynolds Numbers 855
E5.8.4. General Correlations for the Sherwood Number 855

E5.9. Mass Transfer to Nonspherical Particles in Translational Flow 856
E5.9.1. Mass and Heat Transfer to a Particle of Arbitrary Shape at Low Peclet Numbers 856
E5.9.2. Mass Transfer to a Ellipsoidal Particle in Translational Flow 857
E5.9.3. Mass Transfer to Particles of Arbitrary Shape 858
E5.9.4. Mass and Heat Transfer to a Circular Cylinder in Translational Flow 859

E5.10. Transient Mass Transfer to Particles, Drops, and Bubbles in Steady-State Flows 860
E5.10.1. Statement of the Problem 860
E5.10.2. General Correlations for the Sherwood Number 861

Bibliography for Chapter E5 862

E6. Electrical Engineering 865

E6.1. Generalities 865
E6.1.1. Introduction. Basic Notions, Definitions, and Notation 865
E6.1.2. Perfect Elements. Active and Passive Elements 866
E6.1.3. Electric Circuits and Networks. Classification of Electric Circuits and Their Operation Modes 867
E6.1.4. Structure Elements of Network. Notion of the Graph of a Network . . 868
E6.1.5. Physical Laws for Structure Elements 868
E6.1.6. Problems of Analysis and Synthesis of a Network. An Analysis of a Network by Physical Laws. Potential Diagram 869

E6.2. Linear Circuits of Direct Current 871
E6.2.1. Power of Direct Current 871
E6.2.2. Notion of Nonideal Source. Equivalent Circuits and External Characteristics 872
E6.2.3. Problem of Maximal Power Transfer. The Source Efficiency Factor . 874
E6.2.4. Theorem on Active Impedor (Two-Terminal Network) and Its Application 875
E6.2.5. Two Compensation Theorems. Properties of Linear Circuits: Linearity Theorem and Reciprocity Theorem 876
E6.2.6. Equivalent Transformations in Electrical Networks 877
E6.2.7. Application of Equivalent Transformations in Network Analysis. Convolution Method 878
E6.2.8. Superposition Principle. The Notion of Input and Transfer Conductances (Admittances) 880
E6.2.9. Concise Methods for Analyzing Electric Circuits 881

E6.3. Nonlinear Electric Circuits of Direct Current 884
E6.3.1. Notion of a Nonlinear Element. Several Typical Characteristics of Nonlinear Elements 884
E6.3.2. Equivalent Transformations of Characteristics of Nonlinear Elements 886
E6.3.3. Graphical Method for Analyzing Circuits with Nonlinear Elements . 887

E6.4. Magnetic Circuits 890
E6.4.1. Magnetic Field and Its Parameters 890
E6.4.2. Ampère's Circuital Law 891
E6.4.3. Ohm's Law for Magnetic Circuit 892
E6.4.4. Ferromagnetic Materials and Their Properties 893
E6.4.5. Kirchhoff's Laws for Magnetic Circuits 894
E6.4.6. Analysis of an Unbranched Magnetic Circuit 896
E6.4.7. Analysis of a Branched Magnetic Circuit 898
E6.4.8. Analysis of a Branched Homogeneous Magnetic Circuit with Permanent Magnet 899

E6.5. Single-Phase Harmonic Current Circuits 900
E6.5.1. Effective and Average Values of Sinusoidal Quantities 900

PREFACE

This is a concise multi-subject handbook, which consists of three major parts: mathematics, physics, and applied and engineering sciences. It presents basic notions, formulas, equations, problems, theorems, methods, and laws on each of the subjects in brief form. The absence of proofs and a concise presentation has permitted combining a substantial amount of reference material in a single volume. The handbook is intended for a wide audience of engineers and researchers (not specialized in mathematics or theoretical physics) as well as graduate and postgraduate students.

- The first part of the book contains chapters on arithmetics, elementary and analytic geometry, algebra, differential and integral calculus, functions of complex variable, integral transforms, ordinary and partial differential equations, special functions, probability theory, etc.
- The second part of the book contains chapters on molecular physics and thermodynamics, electricity and magnetism, oscillations and waves, optics, special relativity, quantum mechanics, atomic physics, etc.
- The third part of the book contains chapters on dimensional analysis and similarity, mechanics of point masses and rigid bodies, strength of materials, hydrodynamics, mass and heat transfer, electrical engineering, and methods for constructing empirical and engineering formulas.

A compact and clear presentation of the material allows the reader to get quick help on (or revise) the desired topic. Special attention is paid to issues that many engineers and students may find difficult to understand.

When selecting the material, the authors have given a pronounced preference to practical aspects; namely, to formulas, problems, methods, and laws that most frequently occur in sciences and engineering applications and university education. Many results are represented in tabular form.

For the convenience of a wider audience with different mathematical backgrounds, the authors tried to avoid special terminology whenever possible. Therefore, some of the topics and methods are outlined in a schematic and somewhat simplified manner, which is sufficient for them to be used successfully in most cases. Many sections were written so that they could be read independently. The material within subsections is arranged in increasing order of complexity. This allows the reader to get to the heart of the matter quickly.

The material of the reference book can be roughly categorized into the following three groups according to meaning:

1. The main text containing a concise, coherent survey of the most important definitions, formulas, equations, methods, theorems, and laws.
2. For the reader's better understanding of the topics and methods under study, numerous examples are given throughout the book.
3. Discussion of additional issues of interest, given in the form of remarks in small print.

For the reader's convenience, several long mathematical tables—indefinite and definite integrals, direct and inverse integral transforms (Laplace, Mellin, and Fourier transforms), and exact solutions of differential equations—which contain a large amount of information, are presented in the supplement of the book. Also included are some physical tables and the periodic table of the chemical elements.

This handbook consists of parts, chapters, sections, and subsections. Figures and tables are numbered separately in each section, while formulas (equations) and examples are numbered separately in each subsection. When citing a formula, we use notation like (M3.1.2.5), which means formula 5 in Subsection M3.1.2. For the reader's convenience, each citation number is preceded by a letter to indicate one of the major parts: mathematics (M), physics (P), engineering sciences (E), or supplements (S). At the end of each chapter, we present a list of main and additional literature sources containing more detailed information about topics of interest to the reader.

Special font highlighting in the text, cross-references, an extensive table of contents, and a detailed index help the reader to find the desired information.

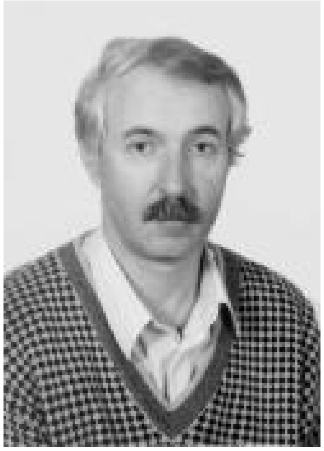
Chapters M1, M2, and M6–M9 were written by V. M. Safrai and A. I. Zhurov, Chapters M3–M5, M10, and M14 by A. V. Manzhirov and V. A. Popov, Chapters M11–M13, E1, E4, E5, E7, and S1–S5 by A. D. Polyanin, Chapters P1–P8 by A. I. Chernoutsan, Chapter E2 by V. D. Polyanin, Chapter E3 by B. V. Putyatin, Chapter E6 by A. V. Egorov and Yu. V. Repina, and Chapters S6 and S7 by A. I. Chernoutsan and A. I. Zhurov. Part M was edited by A. D. Polyanin and parts E and S were edited by A. D. Polyanin and A. I. Chernoutsan.

We would like to express our deep gratitude to Vladimir Nazaikinskii for translating several chapters of this handbook.

The authors hope that this book will be helpful for a wide range of engineers, scientists, university teachers, and students engaged in the fields of physics, mechanics, engineering sciences, chemistry, biology, ecology, medicine as well as social and economical sciences.

Andrei D. Polyanin
Alexei I. Chernoutsan

EDITORS



Andrei D. Polyanin, D.Sc., Ph.D., is a well-known scientist of broad interests and is active in various areas of mathematics, mechanics, and chemical engineering sciences. He is one of the most prominent authors in the field of reference literature on mathematics.

Professor Polyanin graduated with honors from the Department of Mechanics and Mathematics of Moscow State University in 1974. He received his Ph.D. degree in 1981 and D.Sc. degree in 1986 at the Institute for Problems in Mechanics of the Russian (former USSR) Academy of Sciences. Since 1975, Professor Polyanin has been working at the Institute for Problems in Mechanics of the Russian Academy of Sciences; he is also Professor of Mathematics at Bauman Moscow State Technical University. He is a member of the Russian National Committee on Theoretical and Applied Mechanics and of the Mathematics and Mechanics Expert Council of the Higher Certification Committee of the Russian Federation.

Professor Polyanin is an author of more than 30 books in English, Russian, German, and Bulgarian as well as over 140 research papers and three patents. He has written a number of fundamental handbooks, including A. D. Polyanin and V. F. Zaitsev, *Handbook of Exact Solutions for Ordinary Differential Equations*, CRC Press, 1995 and 2003; A. D. Polyanin and A. V. Manzhirov, *Handbook of Integral Equations*, CRC Press, 1998 and 2008; A. D. Polyanin, *Handbook of Linear Partial Differential Equations for Engineers and Scientists*, Chapman & Hall/CRC Press, 2002; A. D. Polyanin, V. F. Zaitsev, and A. Moussiaux, *Handbook of First Order Partial Differential Equations*, Taylor & Francis, 2002; A. D. Polyanin and V. F. Zaitsev, *Handbook of Nonlinear Partial Differential Equations*, Chapman & Hall/CRC Press, 2004, and A. D. Polyanin and A. V. Manzhirov, *Handbook of Mathematics for Engineers and Scientists*, Chapman & Hall/CRC Press, 2007.

Professor Polyanin is Editor-in-Chief of the international scientific-educational Website *EqWorld — The World of Mathematical Equations* (http://eqworld.ipmnet.ru), which is visited by several thousands of users a day worldwide. He is also Editor of the book series *Differential and Integral Equations and Their Applications*, Chapman & Hall/CRC Press, London/Boca Raton. Professor Polyanin is a member of the Editorial Board of the journal *Theoretical Foundations of Chemical Engineering.*

In 1991, Professor Polyanin was awarded a Chaplygin Prize of the Russian Academy of Sciences for his research in mechanics. In 2001, he received an award from the Ministry of Education of the Russian Federation.

Address: Institute for Problems in Mechanics, 101 Vernadsky Ave., Bldg. 1, 119526 Moscow, Russia.

Home page: http://eqworld.ipmnet.ru/polyanin-ew.htm

Alexei I. Chernoutsan, Ph.D., is a prominent scientist in the fields of statistical physics, fluctuation kinetics, phase transitions, and percolation theory. He graduated from the Faculty of Physics of the Moscow State University in 1975. He received his Ph.D. degree in 1980 at the Landau Institute for Theoretical Physics of the Russian (former USSR) Academy of Sciences. Professor Chernoutsan has been a member of staff of the Gubkin Russian State University of Oil and Gas since 1980, Dean of the Faculty of Natural Sciences Education since 2002, and Head of the Department of Physics since 2009.

An experienced and multi-skilled lecturer in general physics, Professor Chernoutsan has taught students of the Gubkin Russian State University of Oil and Gas for many years. He is an active author in the field of popular science and since 1991 he has been Deputy Editor-in-Chief of *Kvant*, a famous Russian educational magazine for students. He is an author of 3 books and more than 80 scientific and educational publications.

Address: Gubkin Russian State University of Oil and Gas, 65 Leninskii Ave., 119991 Moscow, Russia.

Part I

Mathematics

Chapter M1

Arithmetic and Elementary Algebra

M1.1. Real Numbers

M1.1.1. Integer Numbers

► **Natural, integer, even, and odd numbers.** *Natural numbers*: 1, 2, 3, ... (all positive whole numbers).

Integer numbers (or simply *integers*): 0, ±1, ±2, ±3, ...

Even numbers: 0, 2, 4, ... (all nonnegative integers that can be divided evenly by 2). An even number can generally be represented as $n = 2k$, where $k = 0, 1, 2, \ldots$

Remark 1. Sometimes all integers that are multiples of 2, such as 0, ±2, ±4, ..., are considered to be even numbers.

Odd numbers: 1, 3, 5, ... (all natural numbers that cannot be divided evenly by 2). An odd number can generally be represented as $n = 2k + 1$, where $k = 0, 1, 2, \ldots$

Remark 2. Sometimes all integers that are not multiples of 2, such as ±1, ±3, ±5, ..., are considered to be odd numbers.

All integers as well as even numbers and odd numbers form *infinite countable sets*, which means that the elements of these sets can be enumerated using the natural numbers 1, 2, 3, ...

► **Prime and composite numbers.** A *prime number* is a positive integer that is greater than 1 and has no positive integer divisors other than 1 and itself. The prime numbers form an infinite countable set. The first ten prime numbers are: 2, 3, 5, 7, 11, 13, 17, 19, 23, 29, ...

A *composite number* is a positive integer that is greater than 1 and is not prime, i.e., has factors other than 1 and itself. Any composite number can be uniquely factored into a product of prime numbers. The following numbers are composite: $4 = 2 \times 2$, $6 = 2 \times 3$, $8 = 2^3$, $9 = 3^2$, $10 = 2 \times 5$, $12 = 2^2 \times 3$, ...

The number 1 is a special case that is considered to be neither composite nor prime.

► **Divisibility tests.** Below are some simple rules helping to determine if an integer is divisible by another integer.

All integers are divisible by 1.

Divisibility by 2: last digit is divisible by 2.

Divisibility by 3: sum of digits is divisible by 3.

Divisibility by 4: two last digits form a number divisible by 4.

Divisibility by 5: last digit is either 0 or 5.

Divisibility by 6: divisible by both 2 and 3.

Divisibility by 9: sum of digits is divisible by 9.

Divisibility by 10: last digit is 0.

Divisibility by 11: the difference between the sum of the odd-numbered digits (1st, 3rd, 5th, etc.) and the sum of the even-numbered digits (2nd, 4th, etc.) is divisible by 11.

Example 1. Let us show that the number 80729 is divisible by 11.

The sum of the odd-numbered digits is $\Sigma_1 = 8 + 7 + 9 = 24$. The sum of the even-numbered digits is $\Sigma_2 = 0 + 2 = 2$. The difference between them is $\Sigma_1 - \Sigma_2 = 22$ and is divisible by 11. Consequently, the original number is also divisible by 11.

► **Greatest common divisor and least common multiple.**

1°. The *greatest common divisor* of natural numbers $a_1, a_2, \ldots, a_n$ is the largest natural number, b, which is a common divisor to $a_1, \ldots, a_n$.

Suppose some positive numbers $a_1, a_2, \ldots, a_n$ are factored into products of primes so that

$$a_1 = p_1^{k_{11}} p_2^{k_{12}} \ldots p_m^{k_{1m}}, \quad a_2 = p_1^{k_{21}} p_2^{k_{22}} \ldots p_m^{k_{2m}}, \quad \ldots, \quad a_n = p_1^{k_{n1}} p_2^{k_{n2}} \ldots p_m^{k_{nm}},$$

where $p_1, p_2, \ldots, p_m$ are different prime numbers and the k_{ij} are nonnegative integers ($i = 1, 2, \ldots, n;\ j = 1, 2, \ldots, m$). Then the greatest common divisor b of $a_1, a_2, \ldots, a_n$ is calculated as

$$b = p_1^{\sigma_1} p_2^{\sigma_2} \ldots p_m^{\sigma_m}, \qquad \sigma_j = \min_{1 \le i \le n} k_{ij}.$$

Example 2. The greatest common divisor of 180 and 280 is $2^2 \times 5 = 20$ due to the following factorization:

$$180 = 2^2 \times 3^2 \times 5 = 2^2 \times 3^2 \times 5^1 \times 7^0,$$
$$280 = 2^3 \times 5 \times 7 = 2^3 \times 3^0 \times 5^1 \times 7^1.$$

2°. The *least common multiple* of n natural numbers $a_1, a_2, \ldots, a_n$ is the smallest natural number, A, that is a multiple of all the a_k.

Suppose some natural numbers $a_1, \ldots, a_n$ are factored into products of primes just as in Item 1°. Then the least common multiple of all the a_k is calculated as

$$A = p_1^{\nu_1} p_2^{\nu_2} \ldots p_m^{\nu_m}, \qquad \nu_j = \max_{1 \le i \le n} k_{ij}.$$

Example 3. The least common multiple of 180 and 280 is equal to $2^3 \times 3^2 \times 5^1 \times 7^1 = 2520$ due to the factorization given in Example 2.

M1.1.2. Real, Rational, and Irrational Numbers

► **Real numbers.** The *real numbers* are all the positive numbers, negative numbers, and zero. Any real number can be represented by a *decimal fraction* (or simply *decimal*), finite or infinite. The set of all real numbers is denoted by $\mathbb{R}$.

All real numbers are categorized into two classes: the *rational* numbers and *irrational* numbers.

► **Rational numbers.** A *rational number* is a real number that can be written as a fraction (ratio) p/q with integer p and q ($q \neq 0$). It is only the rational numbers that can be written in the form of finite (terminating) or periodic (recurring) decimals (e.g., $1/8 = 0.125$ and $1/6 = 0.16666\ldots$). Any integer is a rational number.

The rational numbers form an infinite countable set. The set of all rational numbers is everywhere dense. This means that, for any two distinct rational numbers a and b such that $a < b$, there exists at least one more rational number c such that $a < c < b$, and hence there are infinitely many rational numbers between a and b. (Between any two rational numbers, there always exist irrational numbers.)

► **Irrational numbers.** An *irrational number* is a real number that is not rational; no irrational number can be written as a fraction p/q with integer p and q ($q \neq 0$). To the irrational numbers there correspond nonperiodic (nonrepeating) decimals. Here are examples of irrational numbers: $\sqrt{3} = 1.73205\ldots$, $\pi = 3.14159\ldots$

The set of irrational numbers is everywhere dense, which means that between any two distinct irrational numbers, there are both rational and irrational numbers. The set of irrational numbers is uncountable.

M1.2. Equalities and Inequalities. Arithmetic Operations. Absolute Value

M1.2.1. Equalities and Inequalities

Throughout Subsection 1.2.1, it is assumed that a, b, c, d are real numbers.

► **Basic properties of equalities.**

1. If $a = b$, then $b = a$.
2. If $a = b$, then $a + c = b + c$, where c is any real number; furthermore, if $a + c = b + c$, then $a = b$.
3. If $a = b$, then $ac = bc$, where c is any real number; furthermore, if $ac = bc$ and $c \neq 0$, then $a = b$.
4. If $a = b$ and $b = c$, then $a = c$.
5. If $ab = 0$, then either $a = 0$ or $b = 0$; furthermore, if $ab \neq 0$, then $a \neq 0$ and $b \neq 0$.

► **Basic properties of inequalities.**

1. If $a < b$, then $b > a$.
2. If $a \leq b$ and $b \leq a$, then $a = b$.
3. If $a \leq b$ and $b \leq c$, then $a \leq c$.
4. If $a < b$ and $b \leq c$ (or $a \leq b$ and $b < c$), then $a < c$.
5. If $a < b$ and $c < d$ (or $c = d$), then $a + c < b + d$.
6. If $a \leq b$ and $c > 0$, then $ac \leq bc$.
7. If $a \leq b$ and $c < 0$, then $ac \geq bc$.
8. If $0 < a \leq b$ (or $a \leq b < 0$), then $1/a \geq 1/b$.

M1.2.2. Addition and Multiplication of Numbers

► **Addition of real numbers.** The sum of real numbers is a real number.
Properties of addition:

$$\begin{aligned} &a + 0 = a && \text{(property of zero)},\\ &a + b = b + a && \text{(addition is commutative)},\\ &a + (b + c) = (a + b) + c = a + b + c && \text{(addition is associative)}, \end{aligned}$$

where a, b, c are arbitrary real numbers.

For any real number a, there exists its unique *additive inverse*, or its *opposite*, denoted by $-a$, such that

$$a + (-a) = a - a = 0.$$

► **Multiplication of real numbers.** The product of real numbers is a real number.
Properties of multiplication:

$$\begin{aligned} &a \times 0 = 0 && \text{(property of zero)},\\ &ab = ba && \text{(multiplication is commutative)},\\ &a(bc) = (ab)c = abc && \text{(multiplication is associative)},\\ &a \times 1 = 1 \times a = a && \text{(multiplication by unity)},\\ &a(b + c) = ab + ac && \text{(multiplication is distributive)}, \end{aligned}$$

where a, b, c are arbitrary real numbers.

For any nonzero real number a, there exists its unique *multiplicative inverse*, or its *reciprocal*, denoted by a^{-1} or $1/a$, such that

$$aa^{-1} = 1 \quad (a \neq 0).$$

M1.2.3. Ratios and Proportions

► **Operations with fractions and properties of fractions.** Ratios are written as fractions: $a : b = a/b$. The number a is called the *numerator* and the number b ($b \neq 0$) is called the *denominator* of a fraction.

Properties of fractions and operations with fractions:

$$\frac{a}{1} = a, \qquad \frac{a}{b} = \frac{ab}{bc} = \frac{a:c}{b:c} \qquad \text{(simplest properties of fractions);}$$

$$\frac{a}{b} \pm \frac{c}{b} = \frac{a \pm c}{b}, \qquad \frac{a}{b} \pm \frac{c}{d} = \frac{ad \pm bc}{bd} \qquad \text{(addition and subtraction of fractions);}$$

$$\frac{a}{b} \times c = \frac{ac}{b}, \qquad \frac{a}{b} \times \frac{c}{d} = \frac{ac}{bc} \qquad \text{(multiplication by a number and by a fraction);}$$

$$\frac{a}{b} : c = \frac{a}{bc}, \qquad \frac{a}{b} : \frac{c}{d} = \frac{ad}{bc} \qquad \text{(division by a number and by a fraction).}$$

► **Proportions. Simplest relations. Derivative proportions.** A proportion is an equation with a ratio on each side. A proportion is denoted by $a/b = c/d$ or $a : b = c : d$.

1°. The following simplest relations follow from $a/b = c/d$:

$$ad = bc, \quad \frac{a}{c} = \frac{b}{d}, \quad a = \frac{bc}{d}, \quad b = \frac{ad}{c}.$$

2°. The following derivative proportions follow from $a/b = c/d$:

$$\frac{ma + nb}{pa + qb} = \frac{mc + nd}{pc + qd},$$
$$\frac{ma + nc}{pa + qc} = \frac{mb + nd}{pb + qd},$$

where m, n, p, q are arbitrary real numbers.

Some special cases of the above formulas:

$$\frac{a \pm b}{b} = \frac{c \pm d}{d}, \qquad \frac{a - b}{a + b} = \frac{c - d}{c + d}.$$

M1.2.4. Percentage

► **Definition. Main percentage problems.** A *percentage* is a way of expressing a ratio or a fraction as a whole number, by using 100 as the denominator. One *percent* is one per one hundred, or one hundredth of a whole number; notation: 1%.

Below are the statements of main percentage problems and their solutions.

1°. Find the number b that makes up $p\%$ of a number a. Answer: $b = \frac{ap}{100}$.

2°. Find the number a whose $p\%$ is equal to a number b. Answer: $a = \frac{100\,b}{p}$.

3°. What percentage does a number b make up of a number a? Answer: $p = \frac{100\,b}{a}\%$.

► **Simple and compound percentage.**

1°. *Simple percentage*. Suppose a cash deposit is increased yearly by the same amount defined as a percentage, $p\%$, of the initial deposit, a. Then the amount accumulated after t years is calculated by the simple percentage formula

$$x = a\left(1 + \frac{pt}{100}\right).$$

2°. *Compound percentage*. Suppose a cash deposit is increased yearly by an amount defined as a percentage, $p\%$, of the deposit in the previous year. If a is the initial deposit, then the amount accumulated after t years is calculated by the compound percentage formula

$$x = a\left(1 + \frac{p}{100}\right)^t.$$

M1.2.5. Absolute Value of a Number (Modulus of a Number)

► **Definition.** The absolute value of a real number a, denoted by $|a|$, is defined by the formula

$$|a| = \begin{cases} a & \text{if } a \ge 0, \\ -a & \text{if } a < 0. \end{cases}$$

An important property: $|a| \ge 0$.

► **Some formulas and inequalities.**

1°. The following relations hold true:

$$\begin{aligned} &|a| = |-a| = \sqrt{a^2}, \quad a \le |a|, \\ &\big||a| - |b|\big| \le |a+b| \le |a| + |b|, \\ &\big||a| - |b|\big| \le |a-b| \le |a| + |b|, \\ &|ab| = |a|\,|b|, \quad |a/b| = |a|/|b|. \end{aligned}$$

2°. From the inequalities $|a| \le A$ and $|b| \le B$ it follows that $|a+b| \le A+B$ and $|ab| \le AB$.

M1.3. Powers and Logarithms

M1.3.1. Powers and Roots

► **Powers and roots: the main definitions.** Given a positive real number a and a positive integer n, the nth power of a, written as a^n, is defined as the multiplication of a by itself repeated n times:

$$a^n = \underbrace{a \times a \times a \times \cdots \times a}_{n \text{ multipliers}}.$$

The number a is called the *base* and n is called the *exponent*.

Obvious properties: $0^n = 0$, $1^n = 1$, $a^1 = a$.

Raising to the zeroth power: $a^0 = 1$, where $a \neq 0$.

Raising to a negative power: $a^{-n} = \dfrac{1}{a^n}$, where n is a positive integer.

If a is a positive real number and n is a positive integer, then the *nth arithmetic root* or *radical* of a, written as $\sqrt[n]{a}$, is the unique positive real number b such that $b^n = a$. In the case of $n = 2$, the brief notation $\sqrt{a}$ is used to denote $\sqrt[2]{a}$.

The following relations hold:

$$\sqrt[n]{0} = 0, \qquad \sqrt[n]{1} = 1, \qquad \left(\sqrt[n]{a}\right)^n = a.$$

Raising to a fractional power $p = m/n$, where m and n are natural numbers:

$$a^p = a^{m/n} = \sqrt[n]{a^m}, \qquad a \ge 0.$$

► **Operations with powers and roots.** The properties given below are valid for any real exponents p and q ($a > 0$, $b > 0$):

$$a^{-p} = \frac{1}{a^p}, \quad a^p a^q = a^{p+q}, \quad \frac{a^p}{a^q} = a^{p-q},$$

$$(ab)^p = a^p b^p, \quad \left(\frac{a}{b}\right)^q = \frac{a^q}{b^q}, \quad (a^p)^q = a^{pq}.$$

In operations with roots (radicals) the following properties are used:

$$\sqrt[n]{ab} = \sqrt[n]{a}\,\sqrt[n]{b}, \quad \sqrt[n]{\frac{a}{b}} = \frac{\sqrt[n]{a}}{\sqrt[n]{b}}, \quad \sqrt[n]{a^m} = \left(\sqrt[n]{a}\right)^m, \quad \sqrt[n]{\sqrt[m]{a}} = \sqrt[mn]{a}.$$

Remark. It often pays to represent roots as powers with rational exponents and apply the properties of operations with powers.

M1.3.2. Logarithms

► **Definition. The main logarithmic identity.** The *logarithm of a positive number b to a given base a* is the exponent of the power c to which the base a must be raised to produce b. It is written as $\log_a b = c$.

Equivalent representations:

$$\log_a b = c \quad \Longleftrightarrow \quad a^c = b,$$

where $a > 0$, $a \ne 1$, and $b > 0$.

Main logarithmic identity:

$$a^{\log_a b} = b.$$

Simple properties:

$$\log_a 1 = 0, \qquad \log_a a = 1.$$

► **Properties of logarithms. The common and natural logarithms.** Properties of logarithms:

$$\log_a(bc) = \log_a b + \log_a c, \qquad \log_a\left(\frac{b}{c}\right) = \log_a b - \log_a c,$$

$$\log_a(b^k) = k \log_a b, \qquad \log_{a^k} b = \frac{1}{k}\log_a b \quad (k \ne 0),$$

$$\log_a b = \frac{1}{\log_b a} \quad (b \ne 1), \qquad \log_a b = \frac{\log_c b}{\log_c a} \quad (c \ne 1),$$

where $a > 0$, $a \ne 1$, $b > 0$, $c > 0$, and k is any number.

The logarithm to the base 10 is called the *common* or *decadic logarithm* and written as

$$\log_{10} b = \log b \quad \text{or sometimes} \quad \log_{10} b = \lg b.$$

The logarithm to the base e (the *base of natural logarithms*) is called the *natural logarithm* and written as

$$\log_e b = \ln b,$$

where $e = \lim\limits_{n\to\infty}\left(1 + \frac{1}{n}\right)^n = 2.718281\ldots$

The following relations hold:

$$\ln b \approx 2.30259 \lg b, \quad \lg b \approx 0.43429 \ln b$$

M1.4. Binomial Theorem and Related Formulas

M1.4.1. Factorials. Binomial Coefficients. Binomial Theorem

► **Factorials. Binomial coefficients.**
Factorial:

$$0! = 1! = 1,$$
$$n! = 1\times 2\times 3\times\cdots\times(n-1)\times n, \quad n = 2,\ 3,\ 4,\ \ldots$$

Double factorial:

$$\begin{aligned}0!! &= 1!! = 1,\\ n!! &= \begin{cases}(2k)!! & \text{if } n=2k,\\ (2k+1)!! & \text{if } n=2k+1,\end{cases}\\ (2k)!! &= 2\times 4\times 6\times\cdots\times(2k-2)\times(2k) = 2^k k!,\\ (2k+1)!! &= 1\times 3\times 5\times\cdots\times(2k-1)\times(2k+1),\end{aligned}$$

where n and k are natural numbers.
Binomial coefficients:

$$C_n^k = \binom{n}{k} = \frac{n!}{k!\,(n-k)!} = \frac{n(n-1)\ldots(n-k+1)}{k!}, \quad k = 1,\ 2,\ 3,\ \ldots,\ n;$$
$$C_a^k = \frac{a(a-1)\ldots(a-k+1)}{k!}, \quad \text{where} \quad k = 1,\ 2,\ 3,\ \ldots,$$

where n is a natural number and a is any number.

► **Binomial theorem.** Let a, b, and c be real (or complex) numbers. The following formulas hold true:

$$\begin{aligned}(a\pm b)^2 &= a^2 \pm 2ab + b^2,\\ (a\pm b)^3 &= a^3 \pm 3a^2b + 3ab^2 \pm b^3,\\ (a\pm b)^4 &= a^4 \pm 4a^3b + 6a^2b^2 \pm 4ab^3 + b^4,\\ &\cdots\cdots\cdots\cdots\cdots\cdots\\ (a+b)^n &= \sum_{k=0}^{n} C_n^k a^{n-k} b^k, \quad n = 1,\ 2,\ \ldots\end{aligned}$$

The last formula is known as the *binomial theorem*, where the C_n^k are binomial coefficients.

M1.4.2. Related Formulas

► **Formulas involving powers ≤ 4.**

$$\begin{aligned}a^2 - b^2 &= (a-b)(a+b),\\ a^3 + b^3 &= (a+b)(a^2 - ab + b^2),\\ a^3 - b^3 &= (a-b)(a^2 + ab + b^2),\\ a^4 - b^4 &= (a-b)(a+b)(a^2 + b^2),\\ (a+b+c)^2 &= a^2 + b^2 + c^2 + 2ab + 2ac + 2bc,\\ a^4 + a^2b^2 + b^4 &= (a^2 + ab + b^2)(a^2 - ab + b^2).\end{aligned}$$

► **Formulas involving arbitrary powers.** Let n be any positive integer. Then

$$a^n - b^n = (a-b)(a^{n-1} + a^{n-2}b + \cdots + ab^{n-2} + b^{n-1}).$$

If n is a positive even number, then

$$\begin{aligned} a^n - b^n &= (a+b)(a^{n-1} - a^{n-2}b + \cdots + ab^{n-2} - b^{n-1}) \\ &= (a-b)(a+b)(a^{n-2} + a^{n-4}b^2 + \cdots + a^2b^{n-4} + b^{n-2}). \end{aligned}$$

If n is a positive odd number, then

$$a^n + b^n = (a+b)(a^{n-1} - a^{n-2}b + \cdots - ab^{n-2} + b^{n-1}).$$

M1.5. Progressions

M1.5.1. Arithmetic Progression

1°. An *arithmetic progression*, or *arithmetic sequence*, is a sequence of real numbers for which each term, starting from the second, is the previous term plus a constant d, called the *common difference*, so that $a_{n+1} = a_n + d$, $n = 1, 2, 3, \ldots$ In general, the terms of an arithmetic progression are expressed as

$$a_n = a_1 + (n-1)d, \qquad n = 1,\ 2,\ 3,\ \ldots,$$

where a_1 is the first term of the progression. An arithmetic progression is called *increasing* if $d > 0$ and *decreasing* if $d < 0$.

2°. An arithmetic progression has the property

$$a_n = \tfrac{1}{2}(a_{n-1} + a_{n+1}).$$

3°. The sum of n first terms of an arithmetic progression is calculated as

$$S_n = a_1 + \cdots + a_n = \tfrac{1}{2}(a_1 + a_n)n = \tfrac{1}{2}[2a_1 + (n-1)d]n.$$

M1.5.2. Geometric Progression

1°. A *geometric progression*, or *geometric sequence*, is a sequence of real numbers for which each term, starting from the second, is the previous term multiplied by a constant q, called the *common ratio*, so that $a_{n+1} = a_n q$, $n = 1, 2, 3, \ldots$ In general, the terms of a geometric progression are expressed as

$$a_n = a_1 q^{n-1}, \qquad n = 1,\ 2,\ 3,\ \ldots,$$

where a_1 is the first term of the progression.

2°. A geometric progression with positive terms has the property

$$a_n = \sqrt{a_{n-1}a_{n+1}}.$$

3°. The sum of n first terms of a geometric progression is calculated as $(q \neq 1)$

$$S_n = a_1 + \cdots + a_n = a_1 \frac{1-q^n}{1-q}.$$

M1.6. Mean Values and Some Inequalities

M1.6.1. Arithmetic Mean, Geometric Mean, and Other Mean Values

The *arithmetic mean* of a set of n real numbers $a_1, a_2, \ldots, a_n$ is defined as

$$m_{\rm a} = \frac{a_1 + a_2 + \cdots + a_n}{n}. \qquad (1.6.1.1)$$

Geometric mean of n positive numbers $a_1, a_2, \ldots, a_n$:

$$m_{\rm g} = (a_1 a_2 \ldots a_n)^{1/n}. \qquad (1.6.1.2)$$

Harmonic mean of n real numbers $a_1, a_2, \ldots, a_n$:

$$m_{\rm h} = \frac{n}{(1/a_1) + (1/a_2) + \cdots + (1/a_n)}, \qquad a_k \neq 0. \qquad (1.6.1.3)$$

Quadratic mean (or *root mean square*) of n real numbers $a_1, a_2, \ldots, a_n$:

$$m_{\rm q} = \sqrt{\frac{a_1^2 + a_2^2 + \cdots + a_n^2}{n}}. \qquad (1.6.1.4)$$

M1.6.2. Inequalities for Mean Values

Given n positive numbers $a_1, a_2, \ldots, a_n$, the following inequalities hold true:

$$m_{\rm h} \leq m_{\rm g} \leq m_{\rm a} \leq m_{\rm q}, \qquad (1.6.1.5)$$

where the mean values are defined above by (1.6.1.1)–(1.6.1.4). The equalities in (1.6.1.5) are attained only if $a_1 = a_2 = \cdots = a_n$.

To make it easier to remember, let us rewrite inequalities (1.6.1.5) in words as

$$\boxed{\text{harmonic mean}} \leq \boxed{\text{geometric mean}} \leq \boxed{\text{arithmetic mean}} \leq \boxed{\text{quadratic mean}}.$$

M1.6.3. Some Inequalities of General Form

Let a_k and b_k be real numbers with $k = 1, 2, \ldots, n$.

Generalized triangle inequality:

$$\left|\sum_{k=1}^{n} a_k\right| \leq \sum_{k=1}^{n} |a_k|.$$

Cauchy's inequality (also known as the *Cauchy–Bunyakovsky inequality* or *Cauchy–Schwarz–Bunyakovsky inequality*):

$$\left(\sum_{k=1}^{n} a_k b_k\right)^2 \leq \left(\sum_{k=1}^{n} a_k^2\right)\left(\sum_{k=1}^{n} b_k^2\right).$$

Minkowski's inequality:

$$\left(\sum_{k=1}^{n} |a_k + b_k|^p\right)^{\frac{1}{p}} \leq \left(\sum_{k=1}^{n} |a_k|^p\right)^{\frac{1}{p}} + \left(\sum_{k=1}^{n} |b_k|^p\right)^{\frac{1}{p}}, \qquad p \geq 1.$$

M1.7. Some Mathematical Methods

M1.7.1. Proof by Contradiction

Proof by contradiction (also known as *reductio ad absurdum*) is an indirect method of mathematical proof. It is based on the law of non-contradiction (a statement cannot be true and false at the same time) and includes the following reasoning:

1. Suppose one has to prove some statement S.
2. One assumes that the opposite of S is true.
3. Based on known axioms, definitions, theorems, formulas, and the assumption of Item 2, one arrives at a contradiction (deduces some obviously false statement).
4. One concludes that the assumption of Item 2 is false and hence the original statement S is true, which was to be proved.

Example. (Euclid's proof of the irrationality of the square root of 2 by contradiction.)

1. It is required to prove that $\sqrt{2}$ is an irrational number, that is, a real number that cannot be represented as a fraction p/q, where p and q are both integers.

2. Assume the opposite: $\sqrt{2}$ is a rational number. This means that $\sqrt{2}$ can be represented as a fraction

$$\sqrt{2} = p/q. \tag{1.7.1.1}$$

Without loss of generality the fraction p/q is assumed to be irreducible, implying that p and q are mutually prime (have no common factor other than 1).

3. Square both sides of (1.7.1.1) and then multiply by q^2 to obtain

$$2q^2 = p^2. \tag{1.7.1.2}$$

The left-hand side is divisible by 2. Then the right-hand side, p^2, and hence p is also divisible by 2. Consequently, p is an even number so that

$$p = 2n, \tag{1.7.1.3}$$

where n is an integer. Substituting (1.7.1.3) into (1.7.1.2) and then dividing by 2 yields

$$q^2 = 2p^2. \tag{1.7.1.4}$$

Now it can be concluded, just as above, that q^2 and hence q must be divisible by 2. Consequently, q is an even number so that

$$q = 2m, \tag{1.7.1.5}$$

where m is an integer.

It is now apparent from (1.7.1.3) and (1.7.1.5) that the fraction p/q is not simple, since p and q have a common factor 2. This contradicts the assumption made in Item 2.

4. It follows from the results of Item 3 that the representation of $\sqrt{2}$ in the form of a fraction (1.7.1.1) is false, which means that $\sqrt{2}$ is irrational.

M1.7.2. Mathematical Induction

The method of proof by (complete) *mathematical induction* is based on the following reasoning:

1. Let $A(n)$ be a statement dependent on n with $n = 1, 2, \ldots$ (A is a hypothesis at this stage).
2. Base case. Suppose the initial statement $A(1)$ is true. This is usually established by direct substitution $n = 1$.
3. Induction step. Assume that $A(n)$ is true for any n and then, based on this assumption, prove that $A(n+1)$ is also true.
4. Principle of mathematical induction. From the results of Items 2–3 it is concluded that the statement $A(n)$ is true for any n.

Example.

1. Prove the formula for the sum of odd numbers

$$1 + 3 + 5 + \cdots + (2n - 1) = n^2 \tag{1.7.2.1}$$

for any natural n.

2. For $n = 1$, we have an obvious identity: $1 = 1$.

3. Let us assume that formula (1.7.2.1) holds for any n. To consider the case of $n + 1$, let us add the next term, $(2n + 1)$, to both sides of (1.7.2.1) to obtain

$$1 + 3 + 5 + \cdots + (2n - 1) + (2n + 1) = n^2 + (2n + 1) = (n + 1)^2.$$

Thus, from the assumption of the validity of formula (1.7.2.1) for any n it follows that (1.7.2.1) is also valid for $n + 1$.

4. According to the principle of mathematical induction, this proves formula (1.7.2.1).

Remark. The first step, the formulation of an original hypothesis, is the most difficult part of the method of mathematical induction. This step is often omitted from the method.

M1.7.3. Proof by Counterexample

A *counterexample* is an example which is used to prove that a statement (proposition) is false. Counterexamples play an important role in mathematics. Whereas a complicated proof may be the only way to demonstrate the validity of a particular theorem, a single counterexample is all that is needed to refute the validity of a proposed theorem.

In general, the scheme of a proof by counterexample is as follows:

1. Given a proposition: all elements a that belong to a set A also belong to a set (possess a property) B.

2. Refutation of the proposition: one specifies an element a_* (counterexample) that belongs to A but does not belong to B.

Example. *Proposition:* Numbers in the form $2^{2^n} + 1$, where n is a positive integer, were once thought to be prime.

These numbers are prime for $n = 1, 2, 3, 4$. But for $n = 5$, we have a counterexample, since

$$2^{2^5} + 1 = 4294967297 = 641 \times 6700417;$$

it is a composite number.

Conclusion: When faced with a number in the form $2^{2^n} + 1$, we are not allowed to assume it is either prime or composite, unless we know for sure for some other reason.

Chapter M2

Elementary Functions

Basic elementary functions: power, exponential, logarithmic, trigonometric, and inverse trigonometric (arc-trigonometric or antitrigonometric) functions. All other elementary functions are obtained from the basic elementary functions and constants by means of the four arithmetic operations (addition, subtraction, multiplication, and division) and the operation of composition (composite functions).

The graphs and the main properties of the basic as well as some other frequently occurring elementary functions of the real variable are described below.

M2.1. Power, Exponential, and Logarithmic Functions

M2.1.1. Power Function: $y = x^\alpha$ (α is an Arbitrary Real Number)

► **Graphs of the power function.** General properties of the graphs: the point $(1, 1)$ belongs to all the graphs, and $y > 0$ for $x > 0$. For $\alpha > 0$, the graphs pass through the origin $(0, 0)$; for $\alpha < 0$, the graphs have the vertical asymptote $x = 0$ ($y \to +\infty$ as $x \to 0$). For $\alpha = 0$, the graph is a straight line parallel to the x-axis.

Consider more closely the following cases.

Case 1: $y = x^{2n}$, where n is a positive integer ($n = 1, 2, \ldots$). This function is defined for all real x and its range consists of all $y \geq 0$. This function is even, nonperiodic, and unbounded. It crosses the axis Oy and is tangential to the axis Ox at the origin $x = 0$, $y = 0$. On the interval $(-\infty, 0)$ this function decreases, and it increases on the interval $(0, +\infty)$. It attains its minimum value $y = 0$ at $x = 0$. The graph of the function $y = x^2$ (parabola) is given in Fig. M2.1 *a*.

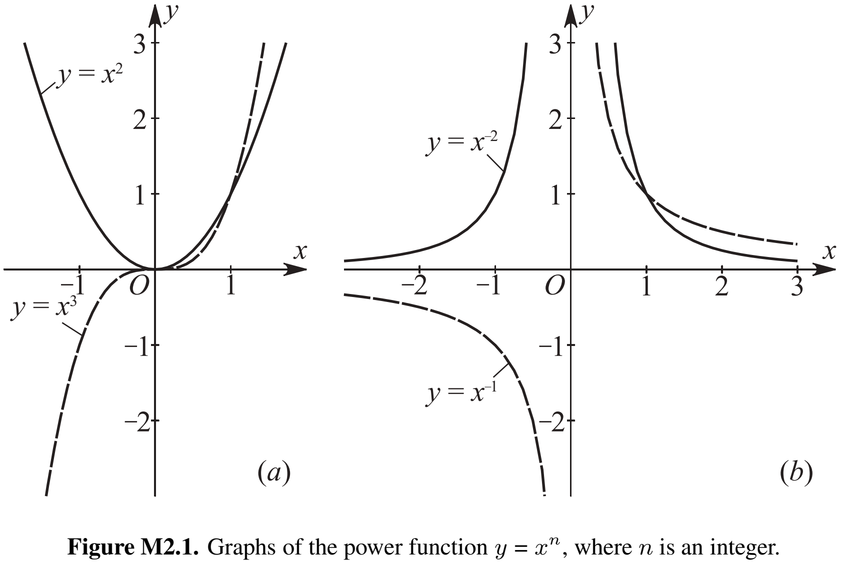

Figure M2.1. Graphs of the power function $y = x^n$, where n is an integer.

Case 2: $y = x^{2n+1}$, where n is a positive integer. This function is defined on the entire x-axis and its range coincides with the y-axis. This function is odd, nonperiodic, and unbounded. It crosses the x-axis and the y-axis at the origin $x = 0$, $y = 0$. It is an increasing function on the entire axis with no points of extremum, the origin being its inflection point. The graph of the function $y = x^3$ (cubic parabola) is shown in Fig. M2.1 *a*.

Case 3: $y = x^{-2n}$, where n is a positive integer. This function is defined for all $x \neq 0$, and its range is the semiaxis $y > 0$. It is an even, nonperiodic, unbounded function having no intersection with the coordinate axes. It increases on the interval $(-\infty, 0)$, decreases on the interval $(0, +\infty)$, and has no points of extremum. The graph of the function has a vertical asymptote $x = 0$. The graph of the function $y = x^{-2}$ is given in Fig. M2.1 *b*.

Case 4: $y = x^{-2n+1}$, where n is a positive integer. This function is defined for all $x \neq 0$, and its range is the entire y-axis. It is an odd, nonperiodic, unbounded function with no intersections with the coordinate axes. This is a decreasing function on the entire axis with no points of extremum. It has a vertical asymptote $x = 0$. The graph of the function $y = x^{-1}$ is given in Fig. M2.1 *b*.

Case 5: $y = x^\alpha$ with a noninteger $\alpha > 0$. This function is defined for all* $x \geq 0$ and its range is the semiaxis $y \geq 0$. This function is neither odd nor even and it is nonperiodic and unbounded. It crosses the axes Ox and Oy at the origin $x = 0$, $y = 0$ and increases everywhere in its domain, taking its smallest value at the point $x = 0$, $y = 0$. The graph of the function $y = x^{1/2}$ is given in Fig. M2.2.

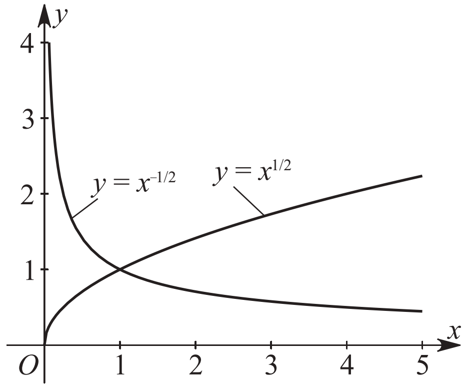

Figure M2.2. Graphs of the power function $y = x^\alpha$, where α is a noninteger.

Case 6: $y = x^\alpha$ with a noninteger $\alpha < 0$. This function is defined for all $x > 0$ and its range is the semiaxis $y > 0$. This function is neither odd nor even, it is nonperiodic and unbounded, and it has no intersections with the coordinate axes, which coincide with its horizontal and vertical asymptotes. This function is decreasing on its entire domain and has no points of extremum. The graph of the function $y = x^{-1/2}$ is given in Fig. M2.2.

► **Properties of the power function.** Basic properties of the power function:

$$x^\alpha x^\beta = x^{\alpha+\beta}, \quad (x_1 x_2)^\alpha = x_1^\alpha x_2^\alpha, \quad (x^\alpha)^\beta = x^{\alpha\beta},$$

for any α and β, where $x > 0$, $x_1 > 0$, $x_2 > 0$.

---

* In fact, the power function $y = x^{1/n}$ with an odd integer n is also defined for all $x < 0$. Here, however, it is always assumed that $x \geq 0$. A similar assumption is made with regard to the functions of the form $y = x^{m/n}$, where m is a positive integer and m/n is an irreducible fraction.

Differentiation and integration formulas:

$$(x^\alpha)' = \alpha x^{\alpha-1}, \qquad \int x^\alpha\,dx = \begin{cases} \dfrac{x^{\alpha+1}}{\alpha+1} + C & \text{if } \alpha \neq -1, \\ \ln|x| + C & \text{if } \alpha = -1. \end{cases}$$

The Taylor series expansion in a neighborhood of an arbitrary point x_0:

$$x^\alpha = \sum_{n=0}^{\infty} C_\alpha^n x_0^{\alpha-n}(x - x_0)^n \quad \text{for} \quad |x - x_0| < |x_0|,$$

where $C_\alpha^n = \dfrac{\alpha(\alpha-1)\dots(\alpha-n+1)}{n!}$ are binomial coefficients.

M2.1.2. Exponential Function: $y = a^x$ $(a > 0,\ a \neq 1)$

► **Graphs of the exponential function.** This function is defined for all x and its range is the semiaxis $y > 0$. This function is neither odd nor even, it is nonperiodic and unbounded, and it crosses the axis Oy at $y = 1$ and does not cross the axis Ox. For $a > 1$, it is an increasing function on the entire x-axis; for $0 < a < 1$, it is a decreasing function. This function has no extremal points; the axis Ox is its horizontal asymptote. The graphs of these functions have the following common property: they pass through the point $(0, 1)$. The graph of $y = a^x$ is symmetrical to the graph of $y = (1/a)^x$ with respect to the y-axis. For $a > 1$, the function a^x grows faster than any power of x as $x \to +\infty$, and it decays faster than any power of $1/x$ as $x \to -\infty$. The graphs of the functions $y = 2^x$ and $y = (1/2)^x$ are given in Fig. M2.3.

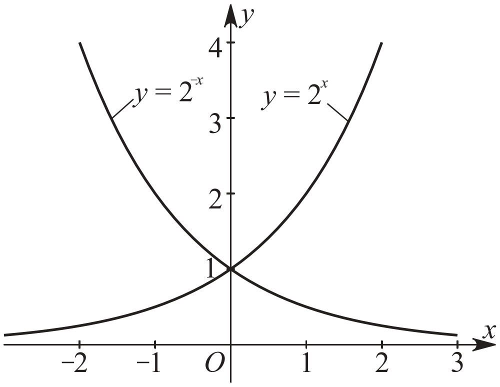

Figure M2.3. Graphs of the exponential function.

► **Properties of the exponential function.** Basic properties of the exponential function:

$$a^{x_1}a^{x_2} = a^{x_1+x_2}, \qquad a^x b^x = (ab)^x, \qquad (a^{x_1})^{x_2} = a^{x_1x_2}.$$

Number e, *base of natural (Napierian) logarithms*, and the function e^x:

$$e = \lim_{n\to\infty}\left(1 + \frac{1}{n}\right)^n = 2.718281\dots, \qquad e^x = \lim_{n\to\infty}\left(1 + \frac{x}{n}\right)^n.$$

The formula for passing from an arbitrary base a to the base e of natural logarithms:

$$a^x = e^{x\ln a}.$$

The inequality

$$a^{x_1} > a^{x_2} \iff \begin{cases} x_1 > x_2 & \text{if } a > 1, \\ x_1 < x_2 & \text{if } 0 < a < 1. \end{cases}$$

The limit relations for any $a > 1$ and $b > 0$:

$$\lim_{x\to+\infty} \frac{a^x}{|x|^b} = \infty, \qquad \lim_{x\to-\infty} a^x|x|^b = 0.$$

Differentiation and integration formulas:

$$(e^x)' = e^x, \qquad \int e^x\,dx = e^x + C;$$

$$(a^x)' = a^x \ln a, \qquad \int a^x\,dx = \frac{a^x}{\ln a} + C.$$

Power series expansion:

$$e^x = 1 + \frac{x}{1!} + \frac{x^2}{2!} + \frac{x^3}{3!} + \cdots + \frac{x^n}{n!} + \cdots = \sum_{k=0}^{\infty} \frac{x^k}{k!}.$$

M2.1.3. Logarithmic Function: $y = \log_a x$ $(a > 0,\ a \neq 1)$

► **Graphs of the logarithmic function.** This function is defined for all $x > 0$ and its range is the entire y-axis. The function is neither odd nor even; it is nonperiodic and unbounded; it crosses the axis Ox at $x = 1$ and does not cross the axis Oy. For $a > 1$, this function is increasing, and for $0 < a < 1$, it is a decreasing function; it has no extremal points, and the axis Oy is its vertical asymptote. The common property of the graphs of such functions is that they all pass through the point $(1, 0)$. The graph of the function $y = \log_a x$ is symmetric to that of $y = \log_{1/a} x$ with respect to the x-axis. The modulus of the logarithmic function tends to infinity slower than any power of x as $x \to +\infty$ and slower than any power of $1/x$ as $x \to +0$. The graphs of the functions $y = \log_2 x$ and $y = \log_{1/2} x$ are shown in Fig. M2.4.

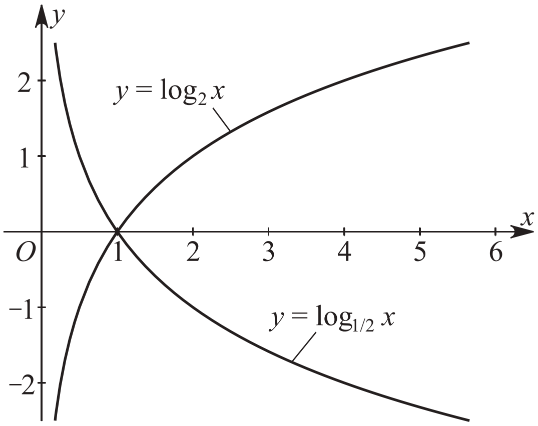

Figure M2.4. Graphs of the logarithmic function.

► **Properties of the logarithmic function.** By definition, the logarithmic function is the inverse of the exponential function. The following equivalence relation holds:

$$y = \log_a x \quad\Longleftrightarrow\quad x = a^y,$$

where $a > 0$, $a \neq 1$.

Basic properties of the logarithmic function:

$$a^{\log_a x} = x, \qquad \log_a(x_1 x_2) = \log_a x_1 + \log_a x_2,$$
$$\log_a(x^k) = k\log_a x, \quad \log_a x = \frac{\log_b x}{\log_b a},$$

where $x > 0$, $x_1 > 0$, $x_2 > 0$, $a > 0$, $a \neq 1$, $b > 0$, $b \neq 1$.

The simplest inequality:

$$\log_a x_1 > \log_a x_2 \quad\Longleftrightarrow\quad \begin{cases} x_1 > x_2 & \text{if } a > 1, \\ x_1 < x_2 & \text{if } 0 < a < 1. \end{cases}$$

For any $b > 0$, the following limit relations hold:

$$\lim_{x\to+\infty} \frac{\log_a x}{x^b} = 0, \qquad \lim_{x\to+0} x^b \log_a x = 0.$$

The logarithmic function with the base e (*base of natural logarithms, Napierian base*) is denoted by

$$\log_e x = \ln x,$$

where $e = \lim\limits_{n\to\infty}\left(1 + \frac{1}{n}\right)^n = 2.718281\ldots$

Formulas for passing from an arbitrary base a to the Napierian base e:

$$\log_a x = \frac{\ln x}{\ln a}.$$

Differentiation and integration formulas:

$$(\ln x)' = \frac{1}{x}, \qquad \int \ln x\,dx = x\ln x - x + C.$$

Power series expansion:

$$\ln(1+x) = x - \frac{x^2}{2} + \frac{x^3}{3} - \cdots + (-1)^{n-1}\frac{x^n}{n} + \cdots = \sum_{k=1}^{\infty}(-1)^{k-1}\frac{x^k}{k}, \qquad -1 < x \leq 1.$$

M2.2. Trigonometric Functions

M2.2.1. Trigonometric Circle. Definition of Trigonometric Functions

► **Trigonometric circle. Degrees and radians.** *Trigonometric circle* is the circle of unit radius with center at the origin of an orthogonal coordinate system Oxy. The coordinate axes divide the circle into four quarters (*quadrants*); see Fig. M2.5. Consider rotation of the polar radius issuing from the origin O and ending at a point M of the trigonometric circle.

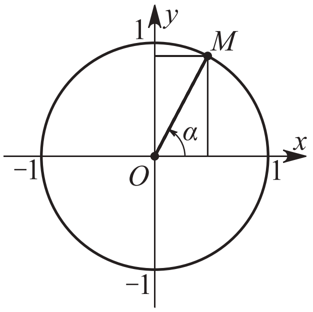

Figure M2.5. Trigonometric circle.

Let α be the angle between the x-axis and the polar radius OM measured from the positive direction of the x-axis. This angle is assumed positive in the case of counterclockwise rotation and negative in the case of clockwise rotation.

Angles are measured either in radians or in degrees. One radian is the angle at the vertex of the sector of the trigonometric circle supported by its arc of unit length. One degree is the angle at the vertex of the sector of the trigonometric circle supported by its arc of length $\pi/180$. The radians are related to the degrees by the formulas

$$1 \text{ radian} = \frac{180^\circ}{\pi}; \qquad 1^\circ = \frac{\pi}{180}.$$

► **Definition of trigonometric functions.** The *sine* of α is the ordinate (the projection to the axis Oy) of the point on the trigonometric circle corresponding to the angle of α radians. The *cosine* of α is the abscissa (projection to the axis Ox) of that point (see Fig. M2.5). The sine and the cosine are basic trigonometric functions and are denoted, respectively, by $\sin\alpha$ and $\cos\alpha$.

Other trigonometric functions are *tangent*, *cotangent*, *secant*, and *cosecant*. These are derived from the basic trigonometric functions, sine and cosine, as follows:

$$\tan\alpha = \frac{\sin\alpha}{\cos\alpha}, \qquad \cot\alpha = \frac{\cos\alpha}{\sin\alpha}, \qquad \sec\,\alpha = \frac{1}{\cos\alpha}, \qquad \operatorname{cosec}\alpha = \frac{1}{\sin\alpha}.$$

Table M2.1 gives the signs of the trigonometric functions in different quadrants. The signs and the values of $\sin\alpha$ and $\cos\alpha$ do not change if the argument α is incremented by $\pm 2\pi n$, where $n = 1,\ 2,\ \ldots$ The signs and the values of $\tan\alpha$ and $\cot\alpha$ do not change if the argument α is incremented by $\pm\pi n$, where $n = 1,\ 2,\ \ldots$

TABLE M2.1
Signs of trigonometric functions in different quarters.

Quarter	Angle in radians	$\sin\alpha$	$\cos\alpha$	$\tan\alpha$	$\cot\alpha$	$\sec\alpha$	$\operatorname{cosec}\alpha$
I	$0<\alpha<\frac{\pi}{2}$	+	+	+	+	+	+
II	$\frac{\pi}{2}<\alpha<\pi$	+	−	−	−	−	+
III	$\pi<\alpha<\frac{3\pi}{2}$	−	−	+	+	−	−
IV	$\frac{3\pi}{2}<\alpha<2\pi$	−	+	−	−	+	−

TABLE M2.2
Numerical values of trigonometric functions for some angles α (in radians).

Angle α	0	$\frac{\pi}{6}$	$\frac{\pi}{4}$	$\frac{\pi}{3}$	$\frac{\pi}{2}$	$\frac{2\pi}{3}$	$\frac{3\pi}{4}$	$\frac{5\pi}{6}$	π
$\sin\alpha$	0	$\frac{1}{2}$	$\frac{\sqrt{2}}{2}$	$\frac{\sqrt{3}}{2}$	1	$\frac{\sqrt{3}}{2}$	$\frac{\sqrt{2}}{2}$	$\frac{1}{2}$	0
$\cos\alpha$	1	$\frac{\sqrt{3}}{2}$	$\frac{\sqrt{2}}{2}$	$\frac{1}{2}$	0	$-\frac{1}{2}$	$-\frac{\sqrt{2}}{2}$	$-\frac{\sqrt{3}}{2}$	-1
$\tan\alpha$	0	$\frac{\sqrt{3}}{3}$	1	$\sqrt{3}$	∞	$-\sqrt{3}$	-1	$-\frac{\sqrt{3}}{3}$	0
$\cot\alpha$	∞	$\sqrt{3}$	1	$\frac{\sqrt{3}}{3}$	0	$-\frac{\sqrt{3}}{3}$	-1	$-\sqrt{3}$	∞

Table M2.2 gives the values of trigonometric functions for some values of their argument (the symbol ∞ means that the function is undefined for the corresponding value of its argument).

M2.2.2. Graphs of Trigonometric Functions

► **Sine: $y = \sin x$.** This function is defined for all x and its range is $y \in [-1, 1]$. The sine is an odd, bounded, periodic function (with period 2π). It crosses the axis Oy at the point $y = 0$ and crosses the axis Ox at the points $x = \pi n$, $n = 0, \pm 1, \pm 2, \ldots$ The sine is an increasing function on every segment $[-\frac{\pi}{2} + 2\pi n, \frac{\pi}{2} + 2\pi n]$ and is a decreasing function on every segment $[\frac{\pi}{2} + 2\pi n, \frac{3}{2}\pi + 2\pi n]$. For $x = \frac{\pi}{2} + 2\pi n$, it attains its maximal value ($y = 1$), and for $x = -\frac{\pi}{2} + 2\pi n$ it attains its minimal value ($y = -1$). The graph of the function $y = \sin x$ is called the *sinusoid* or *sine curve* and is shown in Fig. M2.6.

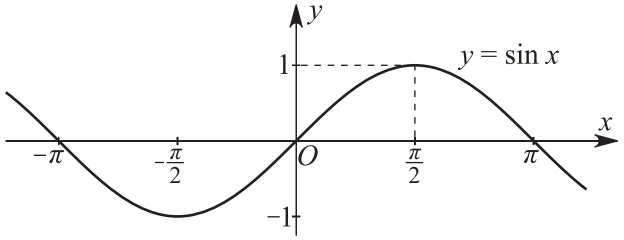

Figure M2.6. Graph of the function $y = \sin x$.

► **Cosine: $y = \cos x$.** This function is defined for all x and its range is $y \in [-1, 1]$. The cosine is a bounded, even, periodic function (with period 2π). It crosses the axis Oy at the point $y = 1$, and crosses the axis Ox at the points $x = \frac{\pi}{2} + \pi n$. The cosine is an increasing function on every segment $[-\pi + 2\pi n, 2\pi n]$ and is a decreasing function on every segment $[2\pi n, \pi + 2\pi n]$, $n = 0, \pm 1, \pm 2, \ldots$ For $x = 2\pi n$ it attains its maximal value ($y = 1$), and for $x = \pi + 2\pi n$ it attains its minimal value ($y = -1$). The graph of the function $y = \cos x$ is a sinusoid obtained by shifting the graph of the function $y = \sin x$ by $\frac{\pi}{2}$ to the left along the axis Ox (see Fig. M2.7).

► **Tangent: $y = \tan x$.** This function is defined for all $x \neq \frac{\pi}{2} + \pi n$, $n = 0, \pm 1, \pm 2, \ldots$, and its range is the entire y-axis. The tangent is an unbounded, odd, periodic function (with period π). It crosses the axis Oy at the point $y = 0$ and crosses the axis Ox at the points $x = \pi n$. This is an increasing function on every interval $(-\frac{\pi}{2} + \pi n, \frac{\pi}{2} + \pi n)$. This function has no points of extremum and has vertical asymptotes at $x = \frac{\pi}{2} + \pi n$, $n = 0, \pm 1, \pm 2, \ldots$ The graph of the function $y = \tan x$ is given in Fig. M2.8.

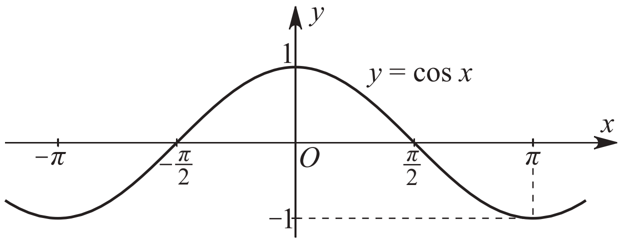

Figure M2.7. Graph of the function $y = \cos x$.

► **Cotangent: $y = \cot x$.** This function is defined for all $x \neq \pi n$, $n = 0, \pm 1, \pm 2, \ldots$, and its range is the entire y-axis. The cotangent is an unbounded, odd, periodic function (with period π). It crosses the axis Ox at the points $x = \frac{\pi}{2} + \pi n$, and does not cross the axis Oy. This is a decreasing function on every interval $(\pi n, \pi + \pi n)$. This function has no extremal points and has vertical asymptotes at $x = \pi n$, $n = 0, \pm 1, \pm 2, \ldots$ The graph of the function $y = \cot x$ is given in Fig. M2.9.

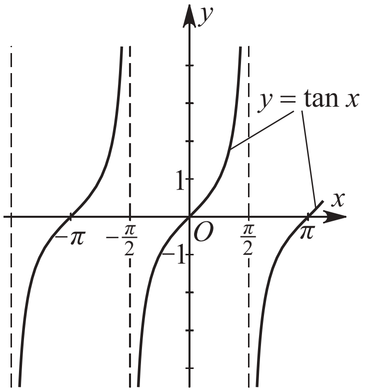

Figure M2.8. Graph of the function $y = \tan x$.

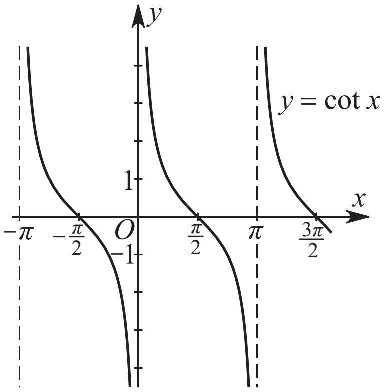

Figure M2.9. Graph of the function $y = \cot x$.

M2.2.3. Properties of Trigonometric Functions

► **Simplest relations.**

$$
\begin{aligned}
&\sin^2 x + \cos^2 x = 1, && \tan x \cot x = 1,\\
&\sin(-x) = -\sin x, && \cos(-x) = \cos x,\\
&\tan x = \frac{\sin x}{\cos x}, && \cot x = \frac{\cos x}{\sin x},\\
&\tan(-x) = -\tan x, && \cot(-x) = -\cot x,\\
&1 + \tan^2 x = \frac{1}{\cos^2 x}, && 1 + \cot^2 x = \frac{1}{\sin^2 x}.
\end{aligned}
$$

► **Reduction formulas.**

$$
\begin{aligned}
&\sin(x \pm 2n\pi) = \sin x, && \cos(x \pm 2n\pi) = \cos x,\\
&\sin(x \pm n\pi) = (-1)^n \sin x, && \cos(x \pm n\pi) = (-1)^n \cos x,\\
&\sin\Bigl(x \pm \frac{2n+1}{2}\pi\Bigr) = \pm(-1)^n \cos x, && \cos\Bigl(x \pm \frac{2n+1}{2}\pi\Bigr) = \mp(-1)^n \sin x,
\end{aligned}
$$

$$\sin\Bigl(x\pm\frac{\pi}{4}\Bigr)=\frac{\sqrt{2}}{2}(\sin x\pm\cos x),\qquad \cos\Bigl(x\pm\frac{\pi}{4}\Bigr)=\frac{\sqrt{2}}{2}(\cos x\mp\sin x),$$
$$\tan(x\pm n\pi)=\tan x,\qquad \cot(x\pm n\pi)=\cot x,$$
$$\tan\Bigl(x\pm\frac{2n+1}{2}\pi\Bigr)=-\cot x,\qquad \cot\Bigl(x\pm\frac{2n+1}{2}\pi\Bigr)=-\tan x,$$
$$\tan\Bigl(x\pm\frac{\pi}{4}\Bigr)=\frac{\tan x\pm 1}{1\mp\tan x},\qquad \cot\Bigl(x\pm\frac{\pi}{4}\Bigr)=\frac{\cot x\mp 1}{1\pm\cot x},$$

where $n = 1, 2, \ldots$

► **Relations between trigonometric functions of single argument.**

$$\begin{aligned}
\sin x &= \pm\sqrt{1-\cos^2 x}=\pm\frac{\tan x}{\sqrt{1+\tan^2 x}}=\pm\frac{1}{\sqrt{1+\cot^2 x}},\\
\cos x &= \pm\sqrt{1-\sin^2 x}=\pm\frac{1}{\sqrt{1+\tan^2 x}}=\pm\frac{\cot x}{\sqrt{1+\cot^2 x}},\\
\tan x &= \pm\frac{\sin x}{\sqrt{1-\sin^2 x}}=\pm\frac{\sqrt{1-\cos^2 x}}{\cos x}=\frac{1}{\cot x},\\
\cot x &= \pm\frac{\sqrt{1-\sin^2 x}}{\sin x}=\pm\frac{\cos x}{\sqrt{1-\cos^2 x}}=\frac{1}{\tan x}.
\end{aligned}$$

The sign before the radical is determined by the quarter in which the argument takes its values.

► **Addition and subtraction of trigonometric functions.**

$$\begin{aligned}
&\sin x+\sin y=2\sin\Bigl(\frac{x+y}{2}\Bigr)\cos\Bigl(\frac{x-y}{2}\Bigr),\\
&\sin x-\sin y=2\sin\Bigl(\frac{x-y}{2}\Bigr)\cos\Bigl(\frac{x+y}{2}\Bigr),\\
&\cos x+\cos y=2\cos\Bigl(\frac{x+y}{2}\Bigr)\cos\Bigl(\frac{x-y}{2}\Bigr),\\
&\cos x-\cos y=-2\sin\Bigl(\frac{x+y}{2}\Bigr)\sin\Bigl(\frac{x-y}{2}\Bigr),\\
&\sin^2 x-\sin^2 y=\cos^2 y-\cos^2 x=\sin(x+y)\sin(x-y),\\
&\sin^2 x-\cos^2 y=-\cos(x+y)\cos(x-y),\\
&\tan x\pm\tan y=\frac{\sin(x\pm y)}{\cos x\cos y},\quad \cot x\pm\cot y=\frac{\sin(y\pm x)}{\sin x\sin y},\\
&a\cos x+b\sin x=r\sin(x+\varphi)=r\cos(x-\psi).
\end{aligned}$$

Here, $r=\sqrt{a^2+b^2}$, $\sin\varphi=a/r$, $\cos\varphi=b/r$, $\sin\psi=b/r$, and $\cos\psi=a/r$.

► **Products of trigonometric functions.**

$$\begin{aligned}
\sin x\sin y&=\tfrac{1}{2}[\cos(x-y)-\cos(x+y)],\\
\cos x\cos y&=\tfrac{1}{2}[\cos(x-y)+\cos(x+y)],\\
\sin x\cos y&=\tfrac{1}{2}[\sin(x-y)+\sin(x+y)].
\end{aligned}$$

▶ Powers of trigonometric functions.

$$\cos^2 x = \tfrac{1}{2}\cos 2x + \tfrac{1}{2}, \qquad \sin^2 x = -\tfrac{1}{2}\cos 2x + \tfrac{1}{2},$$

$$\cos^3 x = \tfrac{1}{4}\cos 3x + \tfrac{3}{4}\cos x, \qquad \sin^3 x = -\tfrac{1}{4}\sin 3x + \tfrac{3}{4}\sin x,$$

$$\cos^4 x = \tfrac{1}{8}\cos 4x + \tfrac{1}{2}\cos 2x + \tfrac{3}{8}, \qquad \sin^4 x = \tfrac{1}{8}\cos 4x - \tfrac{1}{2}\cos 2x + \tfrac{3}{8},$$

$$\cos^5 x = \tfrac{1}{16}\cos 5x + \tfrac{5}{16}\cos 3x + \tfrac{5}{8}\cos x, \qquad \sin^5 x = \tfrac{1}{16}\sin 5x - \tfrac{5}{16}\sin 3x + \tfrac{5}{8}\sin x,$$

$$\cos^{2n} x = \frac{1}{2^{2n-1}}\sum_{k=0}^{n-1} C_{2n}^{k}\cos[2(n-k)x] + \frac{1}{2^{2n}}C_{2n}^{n},$$

$$\cos^{2n+1} x = \frac{1}{2^{2n}}\sum_{k=0}^{n} C_{2n+1}^{k}\cos[(2n-2k+1)x],$$

$$\sin^{2n} x = \frac{1}{2^{2n-1}}\sum_{k=0}^{n-1}(-1)^{n-k} C_{2n}^{k}\cos[2(n-k)x] + \frac{1}{2^{2n}}C_{2n}^{n},$$

$$\sin^{2n+1} x = \frac{1}{2^{2n}}\sum_{k=0}^{n}(-1)^{n-k} C_{2n+1}^{k}\sin[(2n-2k+1)x].$$

Here, $n = 1,\ 2,\ \ldots$ and $C_m^k = \dfrac{m!}{k!\,(m-k)!}$ are binomial coefficients $(0! = 1)$.

▶ Addition formulas.

$$\sin(x \pm y) = \sin x\cos y \pm \cos x\sin y, \qquad \cos(x \pm y) = \cos x\cos y \mp \sin x\sin y,$$

$$\tan(x \pm y) = \frac{\tan x \pm \tan y}{1 \mp \tan x\tan y}, \qquad \cot(x \pm y) = \frac{1 \mp \tan x\tan y}{\tan x \pm \tan y}.$$

▶ Trigonometric functions of multiple arguments.

$$\cos 2x = 2\cos^2 x - 1 = 1 - 2\sin^2 x, \qquad \sin 2x = 2\sin x\cos x,$$

$$\cos 3x = -3\cos x + 4\cos^3 x, \qquad \sin 3x = 3\sin x - 4\sin^3 x,$$

$$\cos 4x = 1 - 8\cos^2 x + 8\cos^4 x, \qquad \sin 4x = 4\cos x\,(\sin x - 2\sin^3 x),$$

$$\cos 5x = 5\cos x - 20\cos^3 x + 16\cos^5 x, \qquad \sin 5x = 5\sin x - 20\sin^3 x + 16\sin^5 x,$$

$$\cos(2nx) = 1 + \sum_{k=1}^{n}(-1)^k \frac{n^2(n^2-1)\ldots[n^2-(k-1)^2]}{(2k)!}4^k\sin^{2k} x,$$

$$\cos[(2n+1)x] = \cos x\left\{1+\sum_{k=1}^{n}(-1)^k \frac{[(2n+1)^2-1][(2n+1)^2-3^2]\ldots[(2n+1)^2-(2k-1)^2]}{(2k)!}\sin^{2k} x\right\},$$

$$\sin(2nx) = 2n\cos x\left[\sin x + \sum_{k=1}^{n}(-4)^k \frac{(n^2-1)(n^2-2^2)\ldots(n^2-k^2)}{(2k-1)!}\sin^{2k-1} x\right],$$

$$\sin[(2n+1)x] = (2n+1)\left\{\sin x + \sum_{k=1}^{n}(-1)^k \frac{[(2n+1)^2-1][(2n+1)^2-3^2]\ldots[(2n+1)^2-(2k-1)^2]}{(2k+1)!}\sin^{2k+1} x\right\},$$

$$\tan 2x = \frac{2\tan x}{1-\tan^2 x}, \qquad \tan 3x = \frac{3\tan x - \tan^3 x}{1 - 3\tan^2 x}, \qquad \tan 4x = \frac{4\tan x - 4\tan^3 x}{1 - 6\tan^2 x + \tan^4 x},$$

where $n = 1,\ 2,\ \ldots$

▶ Trigonometric functions of half argument.

$$\sin^2\frac{x}{2}=\frac{1-\cos x}{2},\qquad \cos^2\frac{x}{2}=\frac{1+\cos x}{2},$$
$$\tan\frac{x}{2}=\frac{\sin x}{1+\cos x}=\frac{1-\cos x}{\sin x},\quad \cot\frac{x}{2}=\frac{\sin x}{1-\cos x}=\frac{1+\cos x}{\sin x},$$
$$\sin x=\frac{2\tan\frac{x}{2}}{1+\tan^2\frac{x}{2}},\quad \cos x=\frac{1-\tan^2\frac{x}{2}}{1+\tan^2\frac{x}{2}},\quad \tan x=\frac{2\tan\frac{x}{2}}{1-\tan^2\frac{x}{2}}.$$

▶ Differentiation formulas.

$$\frac{d\sin x}{dx}=\cos x,\quad \frac{d\cos x}{dx}=-\sin x,\quad \frac{d\tan x}{dx}=\frac{1}{\cos^2 x},\quad \frac{d\cot x}{dx}=-\frac{1}{\sin^2 x}.$$

▶ Integration formulas.

$$\int\sin x\,dx=-\cos x+C,\qquad \int\cos x\,dx=\sin x+C,$$
$$\int\tan x\,dx=-\ln|\cos x|+C,\quad \int\cot x\,dx=\ln|\sin x|+C,$$

where C is an arbitrary constant.

▶ Power series expansions.

$$\cos x=1-\frac{x^2}{2!}+\frac{x^4}{4!}-\frac{x^6}{6!}+\cdots+(-1)^n\frac{x^{2n}}{(2n)!}+\cdots\qquad (|x|<\infty),$$
$$\sin x=x-\frac{x^3}{3!}+\frac{x^5}{5!}-\frac{x^7}{7!}+\cdots+(-1)^n\frac{x^{2n+1}}{(2n+1)!}+\cdots\qquad (|x|<\infty),$$
$$\tan x=x+\frac{x^3}{3}+\frac{2x^5}{15}+\frac{17x^7}{315}+\cdots+\frac{2^{2n}(2^{2n}-1)|B_{2n}|}{(2n)!}x^{2n-1}+\cdots\quad (|x|<\pi/2),$$
$$\cot x=\frac{1}{x}-\left(\frac{x}{3}+\frac{x^3}{45}+\frac{2x^5}{945}+\cdots+\frac{2^{2n}|B_{2n}|}{(2n)!}x^{2n-1}+\cdots\right)\qquad (0<|x|<\pi),$$

where B_n are Bernoulli numbers (see Subsection M13.1.2).

▶ Representation in the form of infinite products.

$$\sin x=x\left(1-\frac{x^2}{\pi^2}\right)\left(1-\frac{x^2}{4\pi^2}\right)\left(1-\frac{x^2}{9\pi^2}\right)\ldots\left(1-\frac{x^2}{n^2\pi^2}\right)\ldots$$
$$\cos x=\left(1-\frac{4x^2}{\pi^2}\right)\left(1-\frac{4x^2}{9\pi^2}\right)\left(1-\frac{4x^2}{25\pi^2}\right)\ldots\left(1-\frac{4x^2}{(2n+1)^2\pi^2}\right)\ldots$$

▶ Euler and de Moivre formulas. Relation to hyperbolic functions.

$$e^{y+ix}=e^y(\cos x+i\sin x),\quad (\cos x+i\sin x)^n=\cos(nx)+i\sin(nx),\quad i^2=-1,$$
$$\sin(ix)=i\sinh x,\quad \cos(ix)=\cosh x,\quad \tan(ix)=i\tanh x,\quad \cot(ix)=-i\coth x.$$

M2.3. Inverse Trigonometric Functions

M2.3.1. Definitions. Graphs of Inverse Trigonometric Functions

► **Definitions of inverse trigonometric functions.** *Inverse trigonometric functions* (*arc functions*) are the functions that are inverse to the trigonometric functions. Since the trigonometric functions $\sin x$, $\cos x$, $\tan x$, $\cot x$ are periodic, the corresponding inverse functions, denoted by $\operatorname{Arcsin} x$, $\operatorname{Arccos} x$, $\operatorname{Arctan} x$, $\operatorname{Arccot} x$, are multi-valued. The following relations define the multi-valued inverse trigonometric functions:

$$\begin{aligned} &\sin(\operatorname{Arcsin} x) = x, \quad &&\cos(\operatorname{Arccos} x) = x,\\ &\tan(\operatorname{Arctan} x) = x, \quad &&\cot(\operatorname{Arccot} x) = x. \end{aligned}$$

These functions admit the following verbal definitions: $\operatorname{Arcsin} x$ is the angle whose sine is equal to x; $\operatorname{Arccos} x$ is the angle whose cosine is equal to x; $\operatorname{Arctan} x$ is the angle whose tangent is equal to x; $\operatorname{Arccot} x$ is the angle whose cotangent is equal to x.

The principal (single-valued) branches of the inverse trigonometric functions are denoted by

$$\begin{aligned} &\arcsin x \equiv \sin^{-1} x &&\text{(arcsine is the inverse of sine)},\\ &\arccos x \equiv \cos^{-1} x &&\text{(arccosine is the inverse of cosine)},\\ &\arctan x \equiv \tan^{-1} x &&\text{(arctangent is the inverse of tangent)},\\ &\operatorname{arccot} x \equiv \cot^{-1} x &&\text{(arccotangent is the inverse of cotangent)} \end{aligned}$$

and are determined by the inequalities

$$\begin{aligned} &-\tfrac{\pi}{2} \le \arcsin x \le \tfrac{\pi}{2}, \quad 0 \le \arccos x \le \pi \qquad (-1 \le x \le 1);\\ &-\tfrac{\pi}{2} < \arctan x < \tfrac{\pi}{2}, \quad 0 < \operatorname{arccot} x < \pi \qquad (-\infty < x < \infty). \end{aligned}$$

The following equivalent relations can be taken as definitions of single-valued inverse trigonometric functions:

$$\begin{aligned} &y = \arcsin x, \quad -1 \le x \le 1 &&\Longleftrightarrow \quad x = \sin y, \quad -\frac{\pi}{2} \le y \le \frac{\pi}{2};\\ &y = \arccos x, \quad -1 \le x \le 1 &&\Longleftrightarrow \quad x = \cos y, \quad 0 \le y \le \pi;\\ &y = \arctan x, \quad -\infty < x < +\infty &&\Longleftrightarrow \quad x = \tan y, \quad -\frac{\pi}{2} < y < \frac{\pi}{2};\\ &y = \operatorname{arccot} x, \quad -\infty < x < +\infty &&\Longleftrightarrow \quad x = \cot y, \quad 0 < y < \pi. \end{aligned}$$

The multi-valued and the single-valued inverse trigonometric functions are related by the formulas

$$\begin{aligned} \operatorname{Arcsin} x &= (-1)^n \arcsin x + \pi n,\\ \operatorname{Arccos} x &= \pm \arccos x + 2\pi n,\\ \operatorname{Arctan} x &= \arctan x + \pi n,\\ \operatorname{Arccot} x &= \operatorname{arccot} x + \pi n, \end{aligned}$$

where $n = 0, \pm 1, \pm 2, \ldots$

The graphs of inverse trigonometric functions are obtained from the graphs of the corresponding trigonometric functions by mirror reflection with respect to the straight line $y = x$ (with the domain of each function being taken into account).

▶ **Arcsine: $y = \arcsin x$.** This function is defined for all $x \in [-1, 1]$ and its range is $y \in [-\frac{\pi}{2}, \frac{\pi}{2}]$. The arcsine is an odd, nonperiodic, bounded function that crosses the axes Ox and Oy at the origin $x = 0$, $y = 0$. This is an increasing function in its domain, and it takes its smallest value $y = -\frac{\pi}{2}$ at the point $x = -1$; it takes its largest value $y = \frac{\pi}{2}$ at the point $x = 1$. The graph of the function $y = \arcsin x$ is given in Fig. M2.10.

▶ **Arccosine: $y = \arccos x$.** This function is defined for all $x \in [-1, 1]$ and its range is $y \in [0, \pi]$. It is neither odd nor even. It is a nonperiodic, bounded function that crosses the axis Oy at the point $y = \frac{\pi}{2}$ and crosses the axis Ox at the point $x = 1$. This is a decreasing function in its domain, and at the point $x = -1$ it takes its largest value $y = \pi$; at the point $x = 1$ it takes its smallest value $y = 0$. For all x in its domain, the following relation holds: $\arccos x = \frac{\pi}{2} - \arcsin x$. The graph of the function $y = \arccos x$ is given in Fig. M2.11.

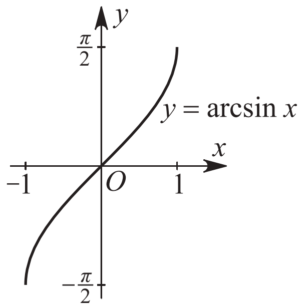

Figure M2.10. Graph of the function $y = \arcsin x$.

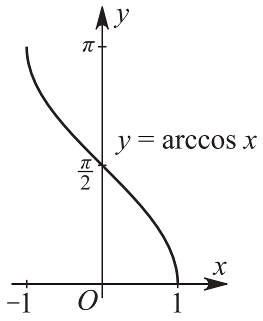

Figure M2.11. Graph of the function $y = \arccos x$.

▶ **Arctangent: $y = \arctan x$.** This function is defined for all x, and its range is $y \in (-\frac{\pi}{2}, \frac{\pi}{2})$. The arctangent is an odd, nonperiodic, bounded function that crosses the coordinate axes at the origin $x = 0$, $y = 0$. This is an increasing function with no points of extremum. It has two horizontal asymptotes: $y = -\frac{\pi}{2}$ (as $x \to -\infty$) and $y = \frac{\pi}{2}$ (as $x \to +\infty$). The graph of the function $y = \arctan x$ is given in Fig. M2.12.

▶ **Arccotangent: $y = \operatorname{arccot} x$.** This function is defined for all x, and its range is $y \in (0, \pi)$. The arccotangent is neither odd nor even. It is a nonperiodic, bounded function that crosses the axis Oy at the point $y = \frac{\pi}{2}$ and does not cross the axis Ox. This is a decreasing function on the entire x-axis with no points of extremum. It has two horizontal asymptotes $y = 0$ (as $x \to +\infty$) and $y = \pi$ (as $x \to -\infty$). For all x, the following relation holds: $\operatorname{arccot} x = \frac{\pi}{2} - \arctan x$. The graph of the function $y = \operatorname{arccot} x$ is given in Fig. M2.13.

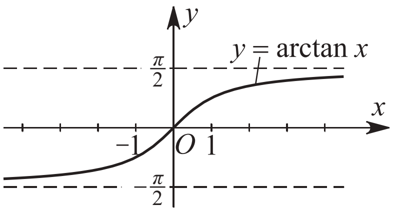

Figure M2.12. Graph of the function $y = \arctan x$.

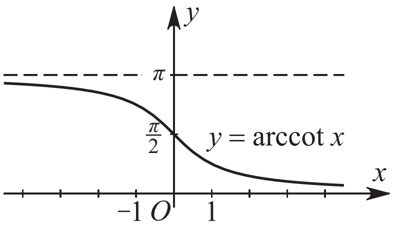

Figure M2.13. Graph of the function $y = \operatorname{arccot} x$.

M2.3.2. Properties of Inverse Trigonometric Functions

▶ **Simplest formulas.**

$$\sin(\arcsin x) = x, \quad \cos(\arccos x) = x,$$
$$\tan(\arctan x) = x, \quad \cot(\operatorname{arccot} x) = x.$$

► Some properties.

$$\arcsin(-x) = -\arcsin x, \qquad \arccos(-x) = \pi - \arccos x,$$
$$\arctan(-x) = -\arctan x, \qquad \operatorname{arccot}(-x) = \pi - \operatorname{arccot} x,$$

$$\arcsin(\sin x) = \begin{cases} x - 2n\pi & \text{if } 2n\pi - \frac{\pi}{2} \le x \le 2n\pi + \frac{\pi}{2}, \\ -x + 2(n+1)\pi & \text{if } (2n+1)\pi - \frac{\pi}{2} \le x \le 2(n+1)\pi + \frac{\pi}{2}, \end{cases}$$

$$\arccos(\cos x) = \begin{cases} x - 2n\pi & \text{if } 2n\pi \le x \le (2n+1)\pi, \\ -x + 2(n+1)\pi & \text{if } (2n+1)\pi \le x \le 2(n+1)\pi, \end{cases}$$

$$\arctan(\tan x) = x - n\pi \quad \text{if} \quad n\pi - \tfrac{\pi}{2} < x < n\pi + \tfrac{\pi}{2},$$
$$\operatorname{arccot}(\cot x) = x - n\pi \quad \text{if} \quad n\pi < x < (n+1)\pi.$$

► Relations between inverse trigonometric functions.

$$\arcsin x + \arccos x = \tfrac{\pi}{2}, \qquad \arctan x + \operatorname{arccot} x = \tfrac{\pi}{2};$$

$$\arcsin x = \begin{cases} \arccos\sqrt{1-x^2} & \text{if } 0 \le x \le 1, \\ -\arccos\sqrt{1-x^2} & \text{if } -1 \le x \le 0, \\ \arctan\dfrac{x}{\sqrt{1-x^2}} & \text{if } -1 < x < 1, \\ \operatorname{arccot}\dfrac{\sqrt{1-x^2}}{x} - \pi & \text{if } -1 \le x < 0; \end{cases} \qquad \arccos x = \begin{cases} \arcsin\sqrt{1-x^2} & \text{if } 0 \le x \le 1, \\ \pi - \arcsin\sqrt{1-x^2} & \text{if } -1 \le x \le 0, \\ \arctan\dfrac{\sqrt{1-x^2}}{x} & \text{if } 0 < x \le 1, \\ \operatorname{arccot}\dfrac{x}{\sqrt{1-x^2}} & \text{if } -1 < x < 1; \end{cases}$$

$$\arctan x = \begin{cases} \arcsin\dfrac{x}{\sqrt{1+x^2}} & \text{for any } x, \\ \arccos\dfrac{1}{\sqrt{1+x^2}} & \text{if } x \ge 0, \\ -\arccos\dfrac{1}{\sqrt{1+x^2}} & \text{if } x \le 0, \\ \operatorname{arccot}\dfrac{1}{x} & \text{if } x > 0; \end{cases} \qquad \operatorname{arccot} x = \begin{cases} \arcsin\dfrac{1}{\sqrt{1+x^2}} & \text{if } x \ge 0, \\ \pi - \arcsin\dfrac{1}{\sqrt{1+x^2}} & \text{if } x \le 0, \\ \arctan\dfrac{1}{x} & \text{if } x > 0, \\ \pi + \arctan\dfrac{1}{x} & \text{if } x < 0. \end{cases}$$

► Addition and subtraction of inverse trigonometric functions.

$$\arcsin x + \arcsin y = \arcsin\bigl(x\sqrt{1-y^2} + y\sqrt{1-x^2}\,\bigr) \qquad \text{for} \quad x^2 + y^2 \le 1,$$
$$\arccos x \pm \arccos y = \pm\arccos\bigl[xy \mp \sqrt{(1-x^2)(1-y^2)}\,\bigr] \qquad \text{for} \quad x \pm y \ge 0,$$
$$\arctan x + \arctan y = \arctan\frac{x+y}{1-xy} \quad \text{for} \quad xy < 1,$$
$$\arctan x - \arctan y = \arctan\frac{x-y}{1+xy} \quad \text{for} \quad xy > -1.$$

► Differentiation formulas.

$$\frac{d}{dx}\arcsin x = \frac{1}{\sqrt{1-x^2}}, \qquad \frac{d}{dx}\arccos x = -\frac{1}{\sqrt{1-x^2}},$$
$$\frac{d}{dx}\arctan x = \frac{1}{1+x^2}, \qquad \frac{d}{dx}\operatorname{arccot} x = -\frac{1}{1+x^2}.$$

► **Integration formulas.**

$$\int \arcsin x\,dx = x\arcsin x + \sqrt{1-x^2} + C, \qquad \int \arccos x\,dx = x\arccos x - \sqrt{1-x^2} + C,$$

$$\int \arctan x\,dx = x\arctan x - \frac{1}{2}\ln(1+x^2) + C, \qquad \int \operatorname{arccot} x\,dx = x\operatorname{arccot} x + \frac{1}{2}\ln(1+x^2) + C,$$

where C is an arbitrary constant.

► **Power series expansions.**

$$\arcsin x = x + \frac{1}{2}\frac{x^3}{3} + \frac{1\times 3}{2\times 4}\frac{x^5}{5} + \frac{1\times 3\times 5}{2\times 4\times 6}\frac{x^7}{7} + \cdots + \frac{1\times 3\times\cdots\times(2n-1)}{2\times 4\times\cdots\times(2n)}\frac{x^{2n+1}}{2n+1} + \cdots \quad (|x|<1),$$

$$\arctan x = x - \frac{x^3}{3} + \frac{x^5}{5} - \frac{x^7}{7} + \cdots + (-1)^{n-1}\frac{x^{2n-1}}{2n-1} + \cdots \quad (|x|\le 1),$$

$$\arctan x = \frac{\pi}{2} - \frac{1}{x} + \frac{1}{3x^3} - \frac{1}{5x^5} + \cdots + (-1)^n\frac{1}{(2n-1)x^{2n-1}} + \cdots \quad (|x|>1).$$

The expansions for $\arccos x$ and $\operatorname{arccot} x$ can be obtained from the relations $\arccos x = \frac{\pi}{2} - \arcsin x$ and $\operatorname{arccot} x = \frac{\pi}{2} - \arctan x$.

M2.4. Hyperbolic Functions

M2.4.1. Definitions. Graphs of Hyperbolic Functions

► **Definitions of hyperbolic functions.** Hyperbolic functions are defined in terms of the exponential functions as follows:

$$\sinh x = \frac{e^x - e^{-x}}{2}, \quad \cosh x = \frac{e^x + e^{-x}}{2}, \quad \tanh x = \frac{e^x - e^{-x}}{e^x + e^{-x}}, \quad \coth x = \frac{e^x + e^{-x}}{e^x - e^{-x}}.$$

The graphs of hyperbolic functions are given below.

► **Hyperbolic sine: $y = \sinh x$.** This function is defined for all x and its range is the entire y-axis. The hyperbolic sine is an odd, nonperiodic, unbounded function that crosses the axes Ox and Oy at the origin $x = 0$, $y = 0$. This is an increasing function in its domain with no points of extremum. The graph of the function $y = \sinh x$ is given in Fig. M2.14.

► **Hyperbolic cosine: $y = \cosh x$.** This function is defined for all x, and its range is $y \in [1, +\infty)$. The hyperbolic cosine is an even, nonperiodic, unbounded function that crosses the axis Oy at $y = 1$ and does not cross the axis Ox. This function is decreasing on the interval $(-\infty, 0)$ and increasing on the interval $(0, +\infty)$; it takes its smallest value $y = 1$ at $x = 0$. The graph of the function $y = \cosh x$ is given in Fig. M2.15.

► **Hyperbolic tangent: $y = \tanh x$.** This function is defined for all x, and its range is $y \in (-1, 1)$. The hyperbolic tangent is an odd, nonperiodic, bounded function that crosses the coordinate axes at the origin $x = 0$, $y = 0$. This is an increasing function on the entire x-axis and has two horizontal asymptotes: $y = -1$ (as $x \to -\infty$) and $y = 1$ (as $x \to +\infty$). The graph of the function $y = \tanh x$ is given in Fig. M2.16.

► **Hyperbolic cotangent: $y = \coth x$.** This function is defined for all $x \ne 0$, and its range consists of all $y \in (-\infty, -1)$ and $y \in (1, +\infty)$. The hyperbolic cotangent is an odd, nonperiodic, unbounded function that does not cross the coordinate axes. This is a decreasing function on each of the semiaxes of its domain; it has no points of extremum. It has two horizontal asymptotes: $y = -1$ (as $x \to -\infty$) and $y = 1$ (as $x \to +\infty$). The graph of the function $y = \coth x$ is given in Fig. M2.17.

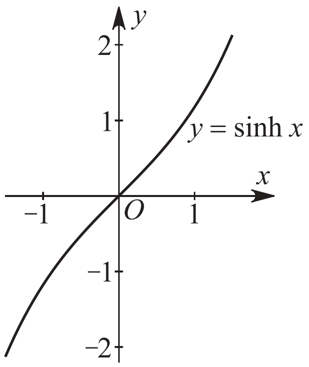

Figure M2.14. Graph of the function $y = \sinh x$.

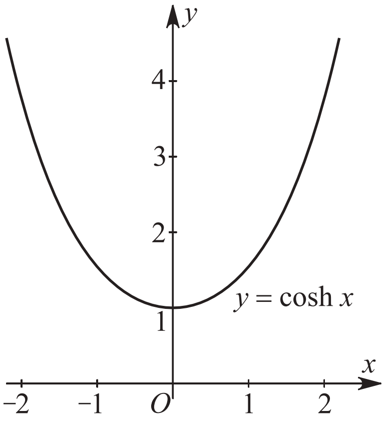

Figure M2.15. Graph of the function $y = \cosh x$.

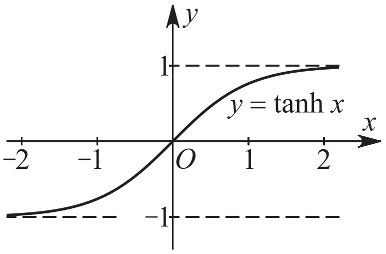

Figure M2.16. Graph of the function $y = \tanh x$.

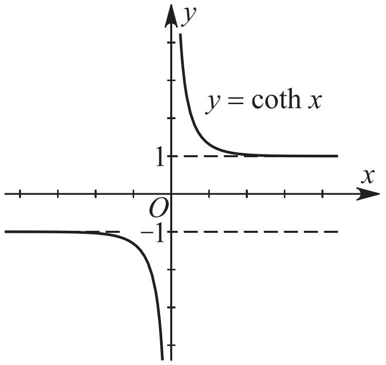

Figure M2.17. Graph of the function $y = \coth x$.

M2.4.2. Properties of Hyperbolic Functions

► **Simplest relations.**

$$\cosh^2 x - \sinh^2 x = 1, \qquad \tanh x \coth x = 1,$$
$$\sinh(-x) = -\sinh x, \qquad \cosh(-x) = \cosh x,$$
$$\tanh x = \frac{\sinh x}{\cosh x}, \qquad \coth x = \frac{\cosh x}{\sinh x},$$
$$\tanh(-x) = -\tanh x, \qquad \coth(-x) = -\coth x,$$
$$1 - \tanh^2 x = \frac{1}{\cosh^2 x}, \qquad \coth^2 x - 1 = \frac{1}{\sinh^2 x}.$$

► **Relations between hyperbolic functions of single argument ($x \geq 0$).**

$$\sinh x = \sqrt{\cosh^2 x - 1} = \frac{\tanh x}{\sqrt{1 - \tanh^2 x}} = \frac{1}{\sqrt{\coth^2 x - 1}},$$
$$\cosh x = \sqrt{\sinh^2 x + 1} = \frac{1}{\sqrt{1 - \tanh^2 x}} = \frac{\coth x}{\sqrt{\coth^2 x - 1}},$$
$$\tanh x = \frac{\sinh x}{\sqrt{\sinh^2 x + 1}} = \frac{\sqrt{\cosh^2 x - 1}}{\cosh x} = \frac{1}{\coth x},$$

$$\coth x = \frac{\sqrt{\sinh^2 x + 1}}{\sinh x} = \frac{\cosh x}{\sqrt{\cosh^2 x - 1}} = \frac{1}{\tanh x}.$$

► **Addition formulas.**

$$\sinh(x \pm y) = \sinh x \cosh y \pm \sinh y \cosh x, \qquad \cosh(x \pm y) = \cosh x \cosh y \pm \sinh x \sinh y,$$

$$\tanh(x \pm y) = \frac{\tanh x \pm \tanh y}{1 \pm \tanh x \tanh y}, \qquad \coth(x \pm y) = \frac{\coth x \coth y \pm 1}{\coth y \pm \coth x}.$$

► **Addition and subtraction of hyperbolic functions.**

$$\sinh x \pm \sinh y = 2\sinh\Big(\frac{x \pm y}{2}\Big)\cosh\Big(\frac{x \mp y}{2}\Big),$$

$$\cosh x + \cosh y = 2\cosh\Big(\frac{x + y}{2}\Big)\cosh\Big(\frac{x - y}{2}\Big),$$

$$\cosh x - \cosh y = 2\sinh\Big(\frac{x + y}{2}\Big)\sinh\Big(\frac{x - y}{2}\Big),$$

$$\sinh^2 x - \sinh^2 y = \cosh^2 x - \cosh^2 y = \sinh(x+y)\sinh(x-y),$$

$$\sinh^2 x + \cosh^2 y = \cosh(x+y)\cosh(x-y),$$

$$(\cosh x \pm \sinh x)^n = \cosh(nx) \pm \sinh(nx),$$

$$\tanh x \pm \tanh y = \frac{\sinh(x \pm y)}{\cosh x \cosh y}, \qquad \coth x \pm \coth y = \pm\frac{\sinh(x \pm y)}{\sinh x \sinh y},$$

where $n = 0, \pm1, \pm2, \ldots$

► **Products of hyperbolic functions.**

$$\sinh x \sinh y = \tfrac{1}{2}[\cosh(x+y) - \cosh(x-y)],$$

$$\cosh x \cosh y = \tfrac{1}{2}[\cosh(x+y) + \cosh(x-y)],$$

$$\sinh x \cosh y = \tfrac{1}{2}[\sinh(x+y) + \sinh(x-y)].$$

► **Powers of hyperbolic functions.**

$$\cosh^2 x = \tfrac{1}{2}\cosh 2x + \tfrac{1}{2}, \qquad \sinh^2 x = \tfrac{1}{2}\cosh 2x - \tfrac{1}{2},$$

$$\cosh^3 x = \tfrac{1}{4}\cosh 3x + \tfrac{3}{4}\cosh x, \qquad \sinh^3 x = \tfrac{1}{4}\sinh 3x - \tfrac{3}{4}\sinh x,$$

$$\cosh^4 x = \tfrac{1}{8}\cosh 4x + \tfrac{1}{2}\cosh 2x + \tfrac{3}{8}, \qquad \sinh^4 x = \tfrac{1}{8}\cosh 4x - \tfrac{1}{2}\cosh 2x + \tfrac{3}{8},$$

$$\cosh^5 x = \tfrac{1}{16}\cosh 5x + \tfrac{5}{16}\cosh 3x + \tfrac{5}{8}\cosh x, \qquad \sinh^5 x = \tfrac{1}{16}\sinh 5x - \tfrac{5}{16}\sinh 3x + \tfrac{5}{8}\sinh x,$$

$$\cosh^{2n} x = \frac{1}{2^{2n-1}}\sum_{k=0}^{n-1} C_{2n}^k \cosh[2(n-k)x] + \frac{1}{2^{2n}}C_{2n}^n,$$

$$\cosh^{2n+1} x = \frac{1}{2^{2n}}\sum_{k=0}^{n} C_{2n+1}^k \cosh[(2n-2k+1)x],$$

$$\sinh^{2n} x = \frac{1}{2^{2n-1}}\sum_{k=0}^{n-1} (-1)^k C_{2n}^k \cosh[2(n-k)x] + \frac{(-1)^n}{2^{2n}}C_{2n}^n,$$

$$\sinh^{2n+1} x = \frac{1}{2^{2n}}\sum_{k=0}^{n} (-1)^k C_{2n+1}^k \sinh[(2n-2k+1)x].$$

Here, $n = 1, 2, \ldots$ and C_m^k are binomial coefficients.

► **Hyperbolic functions of multiple argument.**

$$\cosh 2x = 2\cosh^2 x - 1, \qquad \sinh 2x = 2\sinh x\cosh x,$$

$$\cosh 3x = -3\cosh x + 4\cosh^3 x, \qquad \sinh 3x = 3\sinh x + 4\sinh^3 x,$$

$$\cosh 4x = 1 - 8\cosh^2 x + 8\cosh^4 x, \qquad \sinh 4x = 4\cosh x(\sinh x + 2\sinh^3 x),$$

$$\cosh 5x = 5\cosh x - 20\cosh^3 x + 16\cosh^5 x, \qquad \sinh 5x = 5\sinh x + 20\sinh^3 x + 16\sinh^5 x.$$

$$\cosh(nx) = 2^{n-1}\cosh^n x + \frac{n}{2}\sum_{k=0}^{[n/2]} \frac{(-1)^{k+1}}{k+1} C_{n-k-2}^{k-2} 2^{n-2k-2} (\cosh x)^{n-2k-2},$$

$$\sinh(nx) = \sinh x \sum_{k=0}^{[(n-1)/2]} 2^{n-k-1} C_{n-k-1}^{k} (\cosh x)^{n-2k-1}.$$

Here, C_m^k are binomial coefficients and $[A]$ stands for the integer part of the number A.

► **Hyperbolic functions of half argument.**

$$\sinh\frac{x}{2} = \operatorname{sign} x\sqrt{\frac{\cosh x - 1}{2}}, \qquad \cosh\frac{x}{2} = \sqrt{\frac{\cosh x + 1}{2}},$$

$$\tanh\frac{x}{2} = \frac{\sinh x}{\cosh x + 1} = \frac{\cosh x - 1}{\sinh x}, \qquad \coth\frac{x}{2} = \frac{\sinh x}{\cosh x - 1} = \frac{\cosh x + 1}{\sinh x}.$$

► **Differentiation formulas.**

$$\frac{d\sinh x}{dx} = \cosh x, \qquad \frac{d\cosh x}{dx} = \sinh x,$$

$$\frac{d\tanh x}{dx} = \frac{1}{\cosh^2 x}, \qquad \frac{d\coth x}{dx} = -\frac{1}{\sinh^2 x}.$$

► **Integration formulas.**

$$\int \sinh x\,dx = \cosh x + C, \qquad \int \cosh x\,dx = \sinh x + C,$$

$$\int \tanh x\,dx = \ln\cosh x + C, \qquad \int \coth x\,dx = \ln|\sinh x| + C,$$

where C is an arbitrary constant.

► **Power series expansions.**

$$\cosh x = 1 + \frac{x^2}{2!} + \frac{x^4}{4!} + \frac{x^6}{6!} + \cdots + \frac{x^{2n}}{(2n)!} + \cdots \qquad (|x| < \infty),$$

$$\sinh x = x + \frac{x^3}{3!} + \frac{x^5}{5!} + \frac{x^7}{7!} + \cdots + \frac{x^{2n+1}}{(2n+1)!} + \cdots \qquad (|x| < \infty),$$

$$\tanh x = x - \frac{x^3}{3} + \frac{2x^5}{15} - \frac{17x^7}{315} + \cdots + (-1)^{n-1}\frac{2^{2n}(2^{2n}-1)|B_{2n}|x^{2n-1}}{(2n)!} + \cdots \qquad (|x| < \pi/2),$$

$$\coth x = \frac{1}{x} + \frac{x}{3} - \frac{x^3}{45} + \frac{2x^5}{945} - \cdots + (-1)^{n-1}\frac{2^{2n}|B_{2n}|x^{2n-1}}{(2n)!} + \cdots \qquad (|x| < \pi),$$

where B_n are Bernoulli numbers (see Subsection M13.1.2).

► **Relation to trigonometric functions.**

$$\sinh(ix)=i\sin x,\quad \cosh(ix)=\cos x,\quad \tanh(ix)=i\tan x,\quad \coth(ix)=-i\cot x,\qquad i^2=-1.$$

M2.5. Inverse Hyperbolic Functions

M2.5.1. Definitions. Graphs of Inverse Hyperbolic Functions

► **Definitions of inverse hyperbolic functions.** The *inverse hyperbolic functions* (also known as the *area hyperbolic functions*) are the inverses of the respective hyperbolic functions. The following notation is used for inverse hyperbolic functions:

$$\begin{aligned}
&\operatorname{arcsinh} x \equiv \operatorname{arsinh} x \equiv \sinh^{-1} x && \text{(inverse of hyperbolic sine)},\\
&\operatorname{arccosh} x \equiv \operatorname{arcosh} x \equiv \cosh^{-1} x && \text{(inverse of hyperbolic cosine)},\\
&\operatorname{arctanh} x \equiv \operatorname{artanh} x \equiv \tanh^{-1} x && \text{(inverse of hyperbolic tangent)},\\
&\operatorname{arccoth} x \equiv \operatorname{arcoth} x \equiv \coth^{-1} x && \text{(inverse of hyperbolic cotangent)}.
\end{aligned}$$

Inverse hyperbolic functions can be expressed in terms of logarithmic functions:

$$\begin{aligned}
&\operatorname{arcsinh} x = \ln\bigl(x+\sqrt{x^2+1}\,\bigr) \quad (x \text{ is any}); && \operatorname{arccosh} x = \ln\bigl(x+\sqrt{x^2-1}\,\bigr) \quad (x \ge 1);\\
&\operatorname{arctanh} x = \frac{1}{2}\ln\frac{1+x}{1-x} \quad (|x|<1); && \operatorname{arccoth} x = \frac{1}{2}\ln\frac{x+1}{x-1} \quad (|x|>1).
\end{aligned}$$

Here, only one (principal) branch of the function arccosh x is listed, the function itself being double-valued. In order to write out both branches of arccosh x, the symbol ± should be placed before the logarithm on the right-hand side of the formula.

The graphs of the inverse hyperbolic functions are given below. These are obtained from the graphs of the corresponding hyperbolic functions by mirror reflection with respect to the straight line $y = x$ (with the domain of each function taken into account).

► **Inverse hyperbolic sine: $y = \operatorname{arcsinh} x$.** This function is defined for all x, and its range coincides with the y-axis. The arcsinh x is an odd, nonperiodic, unbounded function that crosses the axes Ox and Oy at the origin $x = 0$, $y = 0$. This is an increasing function on the entire x-axis with no points of extremum. The graph of the function $y = \operatorname{arcsinh} x$ is given in Fig. M2.18.

► **Inverse hyperbolic cosine: $y = \operatorname{arccosh} x$.** This function is defined for all $x \in [1, +\infty)$, and its range consists of $y \in [0, +\infty)$. The arccosh x is neither odd nor even; it is nonperiodic and unbounded. It does not cross the axis Oy and crosses the axis Ox at the point $x = 1$. It is an increasing function in its domain with the minimal value $y = 0$ at $x = 1$. The graph of the function $y = \operatorname{arccosh} x$ is given in Fig. M2.19.

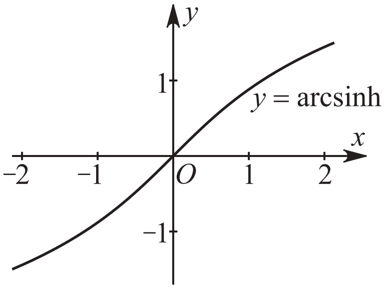

Figure M2.18. Graph of the function $y = \operatorname{arcsinh} x$.

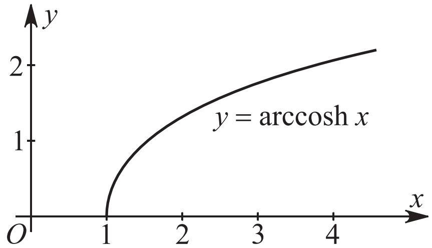

Figure M2.19. Graph of the function $y = \operatorname{arccosh} x$.

► **Inverse hyperbolic tangent: $y = \operatorname{arctanh} x$.** This function is defined for all $x \in (-1, 1)$, and its range consists of all y. The $\operatorname{arctanh} x$ is an odd, nonperiodic, unbounded function that crosses the coordinate axes at the origin $x = 0$, $y = 0$. This is an increasing function in its domain with no points of extremum and an inflection point at the origin. It has two vertical asymptotes: $x = \pm 1$. The graph of the function $y = \operatorname{arctanh} x$ is given in Fig. M2.20.

► **Inverse hyperbolic cotangent: $y = \operatorname{arccoth} x$.** This function is defined for $x \in (-\infty, -1)$ and $x \in (1, +\infty)$. Its range consists of all $y \neq 0$. The $\operatorname{arccoth} x$ is an odd, nonperiodic, unbounded function that does not cross the coordinate axes. It is a decreasing function on each of the semiaxes of its domain. This function has no points of extremum and has one horizontal asymptote $y = 0$ and two vertical asymptotes $x = \pm 1$. The graph of the function $y = \operatorname{arccoth} x$ is given in Fig. M2.21.

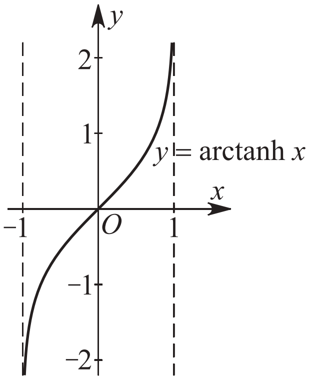

Figure M2.20. Graph of the function $y = \operatorname{arctanh} x$.

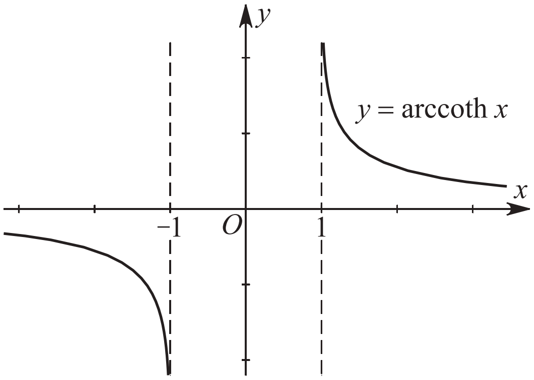

Figure M2.21. Graph of the function $y = \operatorname{arccoth} x$.

M2.5.2. Properties of Inverse Hyperbolic Functions

► **Simplest relations.**

$$\operatorname{arcsinh}(-x) = -\operatorname{arcsinh} x, \quad \operatorname{arctanh}(-x) = -\operatorname{arctanh} x, \quad \operatorname{arccoth}(-x) = -\operatorname{arccoth} x.$$

► **Relations between inverse hyperbolic functions.**

$$\begin{aligned}
\operatorname{arcsinh} x &= \operatorname{arccosh} \sqrt{x^2+1} = \operatorname{arctanh} \frac{x}{\sqrt{x^2+1}},\\
\operatorname{arccosh} x &= \operatorname{arcsinh} \sqrt{x^2-1} = \operatorname{arctanh} \frac{\sqrt{x^2-1}}{x},\\
\operatorname{arctanh} x &= \operatorname{arcsinh} \frac{x}{\sqrt{1-x^2}} = \operatorname{arccosh} \frac{1}{\sqrt{1-x^2}} = \operatorname{arccoth} \frac{1}{x}.
\end{aligned}$$

► **Addition and subtraction of inverse hyperbolic functions.**

$$\begin{gathered}
\operatorname{arcsinh} x \pm \operatorname{arcsinh} y = \operatorname{arcsinh}\left(x\sqrt{1+y^2} \pm y\sqrt{1+x^2}\right),\\
\operatorname{arccosh} x \pm \operatorname{arccosh} y = \operatorname{arccosh}\left[xy \pm \sqrt{(x^2-1)(y^2-1)}\right],\\
\operatorname{arcsinh} x \pm \operatorname{arccosh} y = \operatorname{arcsinh}\left[xy \pm \sqrt{(x^2+1)(y^2-1)}\right],\\
\operatorname{arctanh} x \pm \operatorname{arctanh} y = \operatorname{arctanh} \frac{x \pm y}{1 \pm xy}, \quad \operatorname{arctanh} x \pm \operatorname{arccoth} y = \operatorname{arctanh} \frac{xy \pm 1}{y \pm x}.
\end{gathered}$$

► **Differentiation formulas.**

$$\frac{d}{dx}\operatorname{arcsinh} x = \frac{1}{\sqrt{x^2+1}}, \qquad \frac{d}{dx}\operatorname{arccosh} x = \frac{1}{\sqrt{x^2-1}},$$
$$\frac{d}{dx}\operatorname{arctanh} x = \frac{1}{1-x^2} \quad (x^2<1), \qquad \frac{d}{dx}\operatorname{arccoth} x = \frac{1}{1-x^2} \quad (x^2>1).$$

► **Integration formulas.**

$$\int \operatorname{arcsinh} x\,dx = x\operatorname{arcsinh} x - \sqrt{1+x^2} + C,$$
$$\int \operatorname{arccosh} x\,dx = x\operatorname{arccosh} x - \sqrt{x^2-1} + C,$$
$$\int \operatorname{arctanh} x\,dx = x\operatorname{arctanh} x + \frac{1}{2}\ln(1-x^2) + C,$$
$$\int \operatorname{arccoth} x\,dx = x\operatorname{arccoth} x + \frac{1}{2}\ln(x^2-1) + C,$$

where C is an arbitrary constant.

► **Power series expansions.**

$$\operatorname{arcsinh} x = x - \frac{1}{2}\frac{x^3}{3} + \frac{1\times 3}{2\times 4}\frac{x^5}{5} - \cdots + (-1)^n \frac{1\times 3\times\cdots\times(2n-1)}{2\times 4\times\cdots\times(2n)}\frac{x^{2n+1}}{2n+1} + \cdots \quad (|x|<1),$$
$$\operatorname{arcsinh} x = \ln(2x) + \frac{1}{2}\frac{1}{2x^2} + \frac{1\times 3}{2\times 4}\frac{1}{4x^4} + \cdots + \frac{1\times 3\times\cdots\times(2n-1)}{2\times 4\times\cdots\times(2n)}\frac{1}{2nx^{2n}} + \cdots \quad (|x|>1),$$
$$\operatorname{arccosh} x = \ln(2x) - \frac{1}{2}\frac{1}{2x^2} - \frac{1\times 3}{2\times 4}\frac{1}{4x^4} - \cdots - \frac{1\times 3\times\cdots\times(2n-1)}{2\times 4\times\cdots\times(2n)}\frac{1}{2nx^{2n}} - \cdots \quad (|x|>1),$$
$$\operatorname{arctanh} x = x + \frac{x^3}{3} + \frac{x^5}{5} + \frac{x^7}{7} + \cdots + \frac{x^{2n+1}}{2n+1} + \cdots \quad (|x|<1),$$
$$\operatorname{arccoth} x = \frac{1}{x} + \frac{1}{3x^3} + \frac{1}{5x^5} + \frac{1}{7x^7} + \cdots + \frac{1}{(2n+1)x^{2n+1}} + \cdots \quad (|x|>1).$$

Chapter M3

Elementary Geometry

M3.1. Plane Geometry

M3.1.1. Triangles

► **Plane triangle and its properties.**

1°. A *plane triangle*, or simply a *triangle*, is a plane figure bounded by three straight line segments (*sides*) connecting three noncollinear points (*vertices*) (Fig. M3.1*a*). The smaller angle between the two rays issuing from a vertex and passing through the other two vertices is called an (*interior*) *angle* of the triangle. The angle adjacent to an interior angle is called an *external angle* of the triangle. An external angle is equal to the sum of the two interior angles to which it is not adjacent.

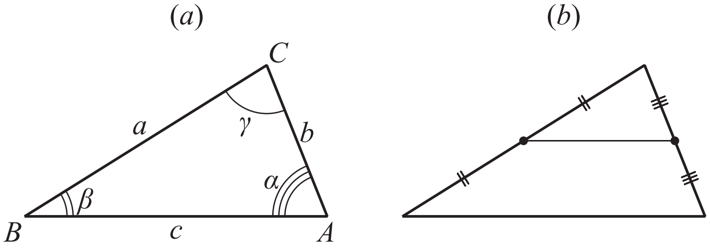

Figure M3.1. Plane triangle (*a*). Midline of a triangle (*b*).

A triangle is uniquely determined by any of the following sets of its parts:

1. Two angles and their included side.
2. Two sides and their included angle.
3. Three sides.

Depending on the angles, a triangle is said to be:

1. *Acute* if all three angles are acute.
2. *Right* (or *right-angled*) if one of the angles is right.
3. *Obtuse* if one of the angles is obtuse.

Depending on the relation between the side lengths, a triangle is said to be:

1. *Regular* (or *equilateral*) if all sides have the same length.
2. *Isosceles* if two of the sides are of equal length.
3. *Scalene* if all sides have different lengths.

2°. *Congruence tests for triangles:*

1. If two sides of a triangle and their included angle are congruent to the corresponding parts of another triangle, then the triangles are congruent.
2. If two angles of a triangle and their included side are congruent to the corresponding parts of another triangle, then the triangles are congruent.

3. If three sides of a triangle are congruent to the corresponding sides of another triangle, then the triangles are congruent.

3°. Triangles are said to be *similar* if their corresponding angles are equal and their corresponding sides are proportional.

Similarity tests for triangles:

1. If all three pairs of corresponding sides in a pair of triangles are in proportion, then the triangles are similar.
2. If two pairs of corresponding angles in a pair of triangles are congruent, then the triangles are similar.
3. If two pairs of corresponding sides in a pair of triangles are in proportion and the included angles are congruent, then the triangles are similar.

The areas of similar triangles are proportional to the squares of the corresponding linear parts (such as sides, altitudes, medians, etc.).

4°. The line connecting the midpoints of two sides of a triangle is called a *midline* of the triangle. The midline is parallel to and half as long as the third side (Fig. M3.1b).

Let a, b, and c be the lengths of the sides of a triangle; let α, β, and γ be the respective opposite angles (Fig. M3.1a); let R and r be the circumradius and the inradius, respectively; and let $p = \frac{1}{2}(a+b+c)$ be the semiperimeter.

Table M3.1 represents the basic properties and relations characterizing triangles.

TABLE M3.1
Basic properties and relations characterizing plane triangles.

No.	The name of property	Properties and relations
1	Triangle inequality	The length of any side of a triangle does not exceed the sum of lengths of the other two sides
2	Sum of angles of a triangle	$\alpha+\beta+\gamma=180^\circ$
3	Law of sines	$\dfrac{a}{\sin\alpha}=\dfrac{b}{\sin\beta}=\dfrac{c}{\sin\gamma}=2R$
4	Law of cosines	$c^2=a^2+b^2-2ab\cos\gamma$
5	Law of tangents	$\dfrac{a+b}{a-b}=\dfrac{\tan\left[\frac{1}{2}(\alpha+\beta)\right]}{\tan\left[\frac{1}{2}(\alpha-\beta)\right]}=\dfrac{\cot\left(\frac{1}{2}\gamma\right)}{\tan\left[\frac{1}{2}(\alpha-\beta)\right]}$
6	Theorem on projections (law of cosines)	$c=a\cos\beta+b\cos\alpha$
7	Trigonometric angle formulas	$\sin\dfrac{\gamma}{2}=\sqrt{\dfrac{(p-a)(p-b)}{ab}},\quad \cos\dfrac{\gamma}{2}=\sqrt{\dfrac{p(p-c)}{ab}},$ $\tan\dfrac{\gamma}{2}=\sqrt{\dfrac{(p-a)(p-b)}{p(p-c)}},\quad \sin\gamma=\dfrac{2}{ab}\sqrt{p(p-a)(p-b)(p-c)}$
8	Law of tangents	$\tan\gamma=\dfrac{c\sin\alpha}{b-c\cos\alpha}=\dfrac{c\sin\beta}{a-c\cos\beta}$
9	Mollweide's formulas	$\dfrac{a+b}{c}=\dfrac{\cos\left[\frac{1}{2}(\alpha-\beta)\right]}{\sin\left(\frac{1}{2}\gamma\right)}=\dfrac{\cos\left[\frac{1}{2}(\alpha-\beta)\right]}{\cos\left[\frac{1}{2}(\alpha+\beta)\right]},$ $\dfrac{a-b}{c}=\dfrac{\sin\left[\frac{1}{2}(\alpha-\beta)\right]}{\cos\left(\frac{1}{2}\gamma\right)}=\dfrac{\sin\left[\frac{1}{2}(\alpha-\beta)\right]}{\sin\left[\frac{1}{2}(\alpha+\beta)\right]}$

Table M3.2 permits one to find the sides and angles of an arbitrary triangle if three appropriately chosen sides and/or angles are given. From the relations given in Tables M3.1 and M3.2, one can derive all missing relations by cyclic permutations of the sides a, b, and c and the angles α, β, and γ.

TABLE M3.2
Solution of plane triangles.

No.	Three parts specified	Formulas for the remaining parts
1	Three sides a, b, c	*First method.* One of the angles is determined by the law of cosines, $\cos\alpha = \dfrac{b^2+c^2-a^2}{2bc}$. Then either the law of sines or the law of cosines is applied. *Second method.* One of the angles is determined by trigonometric angle formulas. Further proceed in a similar way. Remark. The sum of lengths of any two sides must be greater than the length of the third side.
2	Two sides a, b and the included angle γ	*First method.* The side c is determined by the law of cosines, $c = \sqrt{a^2+b^2-2ab\cos\gamma}$. The angle α is determined by either the law of cosines or the law of sines. The angle β is determined from the sum of angles in triangle, $\beta = 180^\circ - \alpha - \gamma$. *Second method.* $\alpha+\beta$ is found from the sum of angles in triangle, $\alpha+\beta = 180^\circ - \gamma$; $\alpha-\beta$ is found from the law of tangents, $\tan\dfrac{\alpha-\beta}{2} = \dfrac{a-b}{a+b}\cot\dfrac{\gamma}{2}$. Then α and β can be found. The third side c is determined by either the law of cosines or the law of sines.
3	A side c and the two angles α, β adjacent to it	The third angle γ is found from the sum of angles in triangle, $\gamma = 180^\circ - \alpha - \beta$. Sides a and b are determined by the law of sines.
4	Two sides a, b and the angle α opposite one of them	The second angle is determined by the law of sines, $\sin\beta = \dfrac{b}{a}\sin\alpha$. The third angle is $\gamma = 180^\circ - \alpha - \beta$. The third side is determined by the law of sines, $c = a\dfrac{\sin\gamma}{\sin\alpha}$. Remark. Five cases are possible: 1. $a > b$; i.e., the angle is opposite the greater side. Then $\alpha > \beta$, $\beta < 90^\circ$ (the larger angle is opposite the larger side), and the triangle is determined uniquely. 2. $a = b$; i.e., the triangle is isosceles and is determined uniquely. 3. $a < b$ and $b\sin\alpha < a$. Then there are two solutions, $\beta_1 + \beta_2 = 180^\circ$. 4. $a < b$ and $b\sin\alpha = a$. Then the solution is unique, $\beta = 90^\circ$. 5. $a < b$ and $b\sin\alpha > a$. Then there are no solutions.

► **Medians, angle bisectors, and altitudes of a triangle.** A straight line through a vertex of a triangle and the midpoint of the opposite side is called a *median* of the triangle (Fig. M3.2*a*). The three medians of a triangle intersect in a single point lying strictly inside the triangle, which is called the *centroid* or *center of gravity* of the triangle. This point cuts the medians in the ratio 2 : 1 (counting from the corresponding vertices).

The length of the median m_a to the side a is equal to

$$m_a = \frac{1}{2}\sqrt{2(b^2+c^2)-a^2} = \frac{1}{2}\sqrt{a^2+4b^2-4ab\cos\gamma}\,. \qquad \text{(M3.1.1.1)}$$

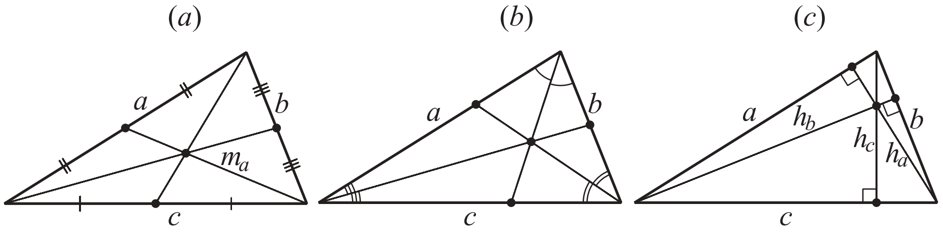

Figure M3.2. Medians (*a*), angle bisectors (*b*), and altitudes (*c*) of a triangle.

An *angle bisector* of a triangle is a line segment between a vertex and a point of the opposite side and dividing the angle at that vertex into two equal parts (Fig. M3.2*b*). The three angle bisectors intersect in a single point lying strictly inside the triangle. This point is equidistant from all sides and is called the *incenter* (the center of the *incircle* of the triangle). The angle bisector through a vertex cuts the opposite side in ratio proportional to the adjacent sides of the triangle.

The length of the angle bisector l_a drawn to the side a is given by the formulas

$$\begin{aligned} l_a &= \frac{\sqrt{bc[(b+c)^2-a^2]}}{b+c} = \frac{\sqrt{4p(p-a)bc}}{b+c}, \\ l_a &= \frac{2cb\cos\left(\frac{1}{2}\alpha\right)}{b+c} = 2R\frac{\sin\beta\sin\gamma}{\cos\left[\frac{1}{2}(\beta-\gamma)\right]} = 2p\frac{\sin\left(\frac{1}{2}\beta\right)\sin\left(\frac{1}{2}\gamma\right)}{\sin\beta+\sin\gamma}, \end{aligned} \qquad \text{(M3.1.1.2)}$$

where R is the circumradius (see below).

An *altitude* of a triangle is a straight line passing through a vertex and perpendicular to the straight line containing the opposite side (Fig. M3.2*c*). The three altitudes of a triangle intersect in a single point, called the *orthocenter* of the triangle.

The length of the altitude h_a to the side a is given by the formulas

$$\begin{aligned} h_a &= b\sin\gamma = c\sin\beta = \frac{bc}{2R}, \\ h_a &= 2(p-a)\cos\frac{\alpha}{2}\cos\frac{\beta}{2}\cos\frac{\gamma}{2} = 2(p-b)\sin\frac{\alpha}{2}\sin\frac{\beta}{2}\cos\frac{\gamma}{2}. \end{aligned} \qquad \text{(M3.1.1.3)}$$

The lengths of the altitude, the angle bisector, and the median through the same vertex satisfy the inequality $h_a \le l_a \le m_a$. If $h_a = l_a = m_a$, then the triangle is isosceles; moreover, the first equality implies the second, and vice versa.

► **Circumcircle and incircle.** A straight line passing through the midpoint of a segment and perpendicular to it is called the *perpendicular bisector* of the segment. The circle passing through the vertices of a triangle is called the *circumcircle* of the triangle. The center O_1 of the circumcircle, called the *circumcenter*, is the point where the perpendicular bisectors of the sides of the triangle meet (Fig. M3.3*a*). The feet of the perpendiculars drawn from a point Q on the circumcircle to the three sides of the triangle lie on the same straight line called the *Simpson line* of Q with respect to the triangle (Fig. M3.3*b*). The circumcenter, the orthocenter, and the centroid lie on a single line, called the *Euler line* (Fig. M3.3*c*).

The circle tangent to the three sides of a triangle and lying inside the triangle is called the *incircle* of the triangle. The center O_2 of the incircle (the *incenter*) is the point where the angle bisectors meet (Fig. M3.4*a*). The straight lines connecting the vertices of a triangle with the points at which the incircle is tangent to the respective opposite sides intersect in a single point G called the *Gergonne point* (Fig. M3.4*b*).

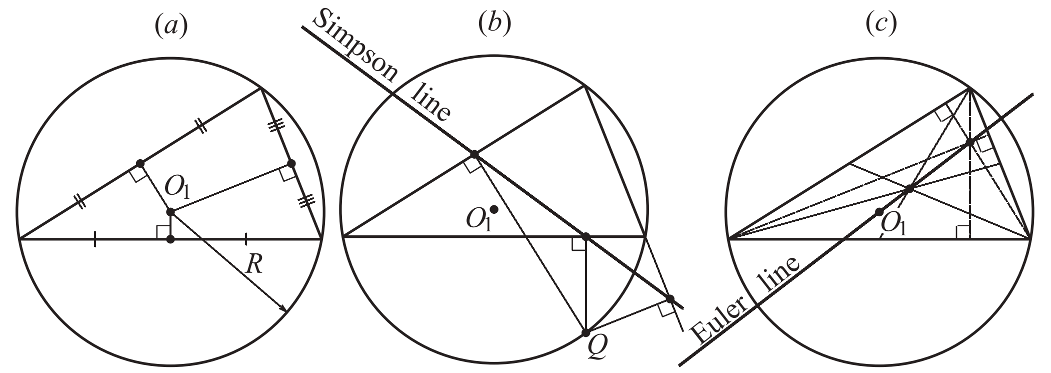

Figure M3.3. The circumcircle of a triangle. The circumcenter (*a*), the Simpson line (*b*), and the Euler line (*c*).

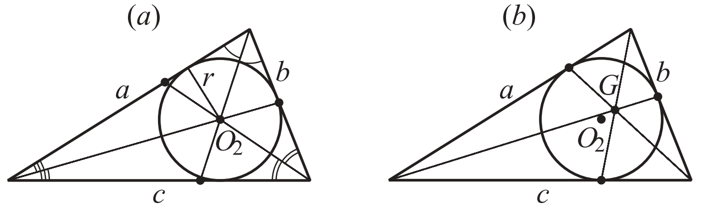

Figure M3.4. The incircle of a triangle (*a*). The incenter and the Gergonne point (*b*).

The inradius r and the circumradius R satisfy the relations

$$r = \sqrt{\frac{(p-a)(p-b)(p-c)}{p}} = p\tan\frac{\alpha}{2}\tan\frac{\beta}{2}\tan\frac{\gamma}{2} = (p-c)\tan\frac{\gamma}{2}, \quad \text{(M3.1.1.4)}$$

$$R = \frac{a}{2\sin\alpha} = \frac{b}{2\sin\beta} = \frac{c}{2\sin\gamma} = \frac{p}{4\cos\left(\frac{1}{2}\alpha\right)\cos\left(\frac{1}{2}\beta\right)\cos\left(\frac{1}{2}\gamma\right)}. \quad \text{(M3.1.1.5)}$$

The distance d between the circumcenter and the incenter is given by the expression

$$d = \sqrt{R^2 - 2Rr}. \quad \text{(M3.1.1.6)}$$

► **Area of a triangle.** The area S of a triangle is given by the formulas

$$S = \tfrac{1}{2}ah_a = \tfrac{1}{2}ab\sin\gamma = rp, \quad \text{(M3.1.1.7)}$$

$$S = \sqrt{p(p-a)(p-b)(p-c)} \quad (\textit{Heron's formula}), \quad \text{(M3.1.1.8)}$$

$$S = \frac{abc}{4R} = 2R^2\sin\alpha\sin\beta\sin\gamma, \quad \text{(M3.1.1.9)}$$

$$S = c^2\frac{\sin\alpha\sin\beta}{2\sin\gamma} = c^2\frac{\sin\alpha\sin\beta}{2\sin(\alpha+\beta)}. \quad \text{(M3.1.1.10)}$$

► **Right (right-angled) triangles.** A *right* triangle is a triangle with a right angle. The side opposite the right angle is called the *hypotenuse*, and the other two sides are called the *legs* (Fig. M3.5).

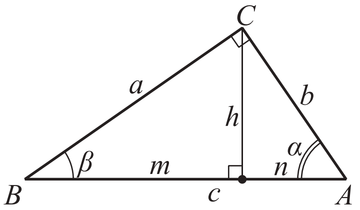

Figure M3.5. A right triangle.

The hypotenuse c, the legs a and b, and the angles α and β opposite the legs satisfy the following relations:

$$\begin{aligned}&\alpha+\beta=90^\circ;\\ &\sin\alpha=\cos\beta=\frac{a}{c},\quad \sin\beta=\cos\alpha=\frac{b}{c},\\ &\tan\alpha=\cot\beta=\frac{a}{b},\quad \tan\beta=\cot\alpha=\frac{b}{a}.\end{aligned}\tag{M3.1.1.11}$$

One also has

$$a^2+b^2=c^2\quad \text{(PYTHAGOREAN THEOREM)},\tag{M3.1.1.12}$$

$$h^2=mn,\quad a^2=mc,\quad b^2=nc,\tag{M3.1.1.13}$$

where h is the length of the altitude drawn to the hypotenuse; moreover, the altitude cuts the hypotenuse into segments of lengths m and n.

In a right triangle, the length of the median m_c drawn from the vertex of the right angle coincides with the circumradius R and is equal to half the length of the hypotenuse c, $m_c=R=\frac{1}{2}c$. The inradius is given by the formula $r=\frac{1}{2}(a+b-c)$. The area of the right triangle is $S=\frac{1}{2}ah_a=\frac{1}{2}ab$ (see also formulas (M3.1.1.4), (M3.1.1.5), and (M3.1.1.9)).

► Isosceles and equilateral triangles.

1°. An *isosceles* triangle is a triangle with two equal sides. These sides are called the *legs*, and the third side is called the *base* (Fig. M3.6*a*).

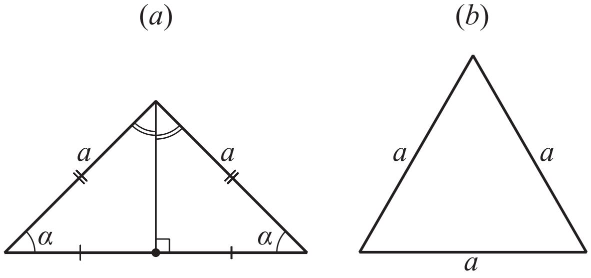

Figure M3.6. An isosceles triangle (*a*). An equilateral triangle (*b*).

Properties of isosceles triangles:

1. In an isosceles triangle, the angles adjacent to the base are equal.
2. In an isosceles triangle, the median drawn to the base is the angle bisector and the altitude.
3. In an isosceles triangle, the sum of distances from a point of the base to the legs is constant.

Criteria for a triangle to be isosceles:

1. If two angles in a triangle are equal, then the triangle is isosceles.
2. If a median in a triangle is also an altitude, then the triangle is isosceles.
3. If a bisector in a triangle is also an altitude, then the triangle is isosceles.

2°. An *equilateral* (or *regular*) triangle is a triangle with all three sides equal (Fig. M3.6*b*). All angles of an equilateral triangle are equal to 60°. In an equilateral triangle, the circumradius R and the inradius r satisfy the relation $R = 2r$.

For an equilateral triangle with side length a, the circumradius and the inradius are given by the formulas $R = \frac{\sqrt{3}}{3}a$ and $r = \frac{\sqrt{3}}{6}a$, and the area is equal to $S = \frac{\sqrt{3}}{4}a^2$.

M3.1.2. Polygons

► **Polygons. Basic information.** A *polygon* is a plane figure bounded by a closed broken line. The straight line segments forming a polygon are called its *sides* (or *edges*). The points at which two sides meet are called the *vertices* (or *corners*) of the polygon. Two sides sharing a vertex, as well as two successive vertices (the endpoints of the same edge), are said to be adjacent. A polygon is said to be *convex* if it lies on one side of any straight line passing through two neighboring vertices. In what follows, we consider only simple convex polygons.

An *(interior) angle* of a convex polygon is the angle between two sides meeting in a vertex. A convex polygon is said to be *inscribed* in a circle if all of its vertices lie on the circle. A polygon is said to be *circumscribed* about a circle if all of its sides are tangent to the circle.

For a convex polygon with n sides, the sum of interior angles is equal to $180°(n-2)$.

One can find the area of an arbitrary polygon by dividing it into triangles.

► **Properties of quadrilaterals.**

1. The diagonals of a convex quadrilateral meet.
2. The sum of interior angles of a convex quadrilateral equals 360° (Figs. M3.7*a* and *b*).
3. The lengths of the sides a, b, c, and d, the diagonals d_1 and d_2, and the segment m connecting the midpoints of the diagonals satisfy the relation $a^2 + b^2 + c^2 + d^2 = d_1^2 + d_2^2 + 4m^2$.
4. A convex quadrilateral is circumscribed if and only if $a + c = b + d$.
5. A convex quadrilateral is inscribed if and only if $\alpha + \gamma = \beta + \delta$.
6. The relation $ac + bd = d_1 d_2$ holds for inscribed quadrilaterals (PTOLEMY'S THEOREM).

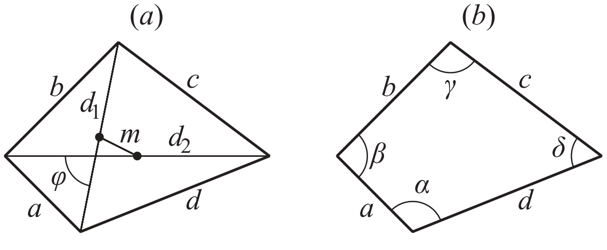

Figure M3.7. Quadrilaterals.

► **Areas of quadrilaterals.** The area of a convex quadrilateral is equal to

$$S = \frac{1}{2} d_1 d_2 \sin\varphi = \sqrt{p(p-a)(p-b)(p-c)(p-d) - abcd\cos^2\frac{\beta+\delta}{2}}, \qquad \text{(M3.1.2.1)}$$

where φ is the angle between the diagonals d_1 and d_2 and $p = \frac{1}{2}(a + b + c + d)$.

The area of an inscribed quadrilateral is

$$S = \sqrt{p(p-a)(p-b)(p-c)(p-d)}. \qquad \text{(M3.1.2.2)}$$

The area of a circumscribed quadrilateral is

$$S = \sqrt{abcd\sin^2\frac{\beta+\delta}{2}}. \qquad \text{(M3.1.2.3)}$$

► **Basic quadrilaterals.**

1°. A *parallelogram* is a quadrilateral such that both pairs of opposite sides are parallel (Fig. M3.8*a*).

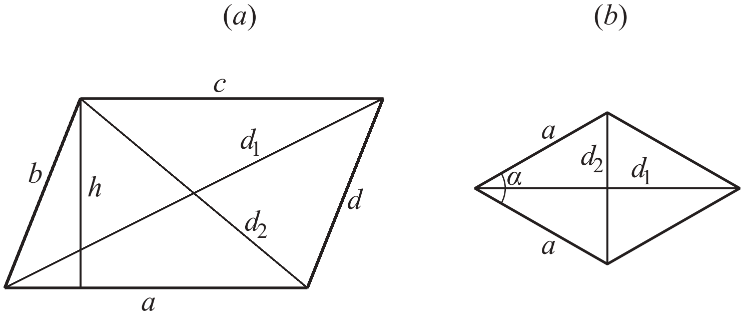

Figure M3.8. A parallelogram (*a*) and a rhombus (*b*).

Attributes of parallelograms (a quadrilateral is a parallelogram if):

1. Both pairs of opposite sides have equal length.
2. Both pairs of opposite angles are equal.
3. Two opposite sides are parallel and have equal length.

Properties of parallelograms:

1. The diagonals meet and bisect each other.
2. Opposite sides have equal length, and opposite angles are equal.
3. The diagonals and the sides satisfy the relation $d_1^2 + d_2^2 = 2(a^2 + b^2)$.
4. The area of a parallelogram is $S = ah$, where h is the altitude.

2°. A *rhombus* is a parallelogram in which all sides are of equal length (Fig. M3.8*b*).

Properties of rhombi:

1. The diagonals are perpendicular.
2. The diagonals are angle bisectors.
3. The area of a rhombus is $S = ah = a^2 \sin\alpha = \frac{1}{2}d_1 d_2$.

3°. A *rectangle* is a parallelogram in which all angles are right angles (Fig. M3.9*a*).

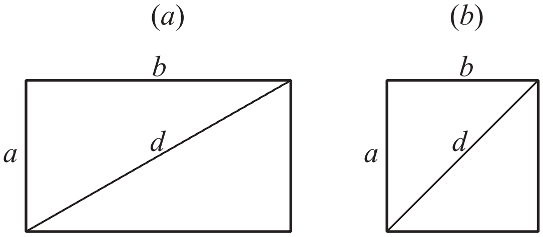

Figure M3.9. A rectangle (*a*) and a square (*b*).

Properties of rectangles:

1. The diagonals have equal lengths.
2. The area of a rectangle is $S = ab$.

4°. A *square* is a rectangle in which all sides have equal lengths (Fig. M3.9*b*). A square is also a rhombus with right angles.

Properties of squares:

1. All angles are right angles.
2. The diagonals are equal to $d = a\sqrt{2}$.
3. The diagonals meet at a right angle and are angle bisectors.
4. The area of a square is equal to $S = a^2 = \frac{1}{2}d^2$.

5°. A *trapezoid* is a quadrilateral in which two sides are parallel and the other two sides are nonparallel (Fig. M3.10). The parallel sides a and b are called the *bases* of the trapezoid, and the other two sides are called the *legs*. In an *isosceles* trapezoid, the legs are of equal length. The line segment connecting the midpoints of the legs is called the *median* of the trapezoid. The length of the median is equal to half the sum of the lengths of the bases, $m = \frac{1}{2}(a + b)$.

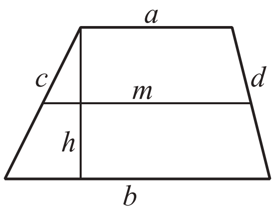

Figure M3.10. A trapezoid.

The perpendicular distance between the bases is called the *altitude* of a trapezoid.

Properties of trapezoids:

1. A trapezoid is circumscribed if and only if $a + b = c + d$.
2. A trapezoid is inscribed if and only if it is isosceles.
3. The area of a trapezoid is $S = \frac{1}{2}(a + b)h = mh = \frac{1}{2}d_1 d_2 \sin\varphi$, where φ is the angle between the diagonals d_1 and d_2.
4. The segment connecting the midpoints of the diagonals is parallel to the bases and has the length $\frac{1}{2}(b - a)$.

► **Regular polygons.** A convex polygon is said to be *regular* if all of its sides have the same length and all of its interior angles are equal. A convex n-gon is regular if and only if it is taken to itself by the rotation by an angle of $2\pi/n$ about some point O. The point O is called the *center* of the regular polygon. The angle between two rays issuing from the center and passing through two neighboring vertices is called the *central angle* (Fig. M3.11).

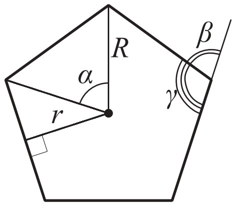

Figure M3.11. A regular polygon.

Properties of regular polygons:

1. The center is equidistant from all vertices as well as from all sides of a regular polygon.
2. A regular polygon is simultaneously inscribed and circumscribed; the centers of the circumcircle and the incircle coincide with the center of the polygon itself.
3. In a regular polygon, the central angle is $\alpha = 360°/n$, the external angle is $\beta = 360°/n$, and the interior angle is $\gamma = 180° - \beta$.
4. The circumradius R, the inradius r, and the side length a of a regular polygon satisfy the relations

$$a = 2\sqrt{R^2 - r^2} = 2R \sin\frac{\alpha}{2} = 2r \tan\frac{\alpha}{2}. \qquad \text{(M3.1.2.4)}$$

5. The area S of a regular n-gon is given by the formula

$$S = \frac{arn}{2} = nr^2 \tan\frac{\alpha}{2} = nR^2 \sin\frac{\alpha}{2} = \frac{1}{4}na^2 \cot\frac{\alpha}{2}. \qquad \text{(M3.1.2.5)}$$

Table M3.3 presents several useful formulas for regular polygons.

TABLE M3.3
Regular polygons (a is the side length).

No.	Name	Inradius r	Circumradius R	Area S
1	Regular polygon	$\dfrac{a}{2\tan\frac{\pi}{n}}$	$\dfrac{a}{2\sin\frac{\pi}{n}}$	$\dfrac{1}{2}arn$
2	Triangle	$\dfrac{\sqrt{3}}{6}a$	$\dfrac{\sqrt{3}}{3}a$	$\dfrac{\sqrt{3}}{4}a^2$
3	Square	$\dfrac{1}{2}a$	$\dfrac{1}{\sqrt{2}}a$	a^2
4	Pentagon	$\sqrt{\dfrac{5+2\sqrt{5}}{20}}\,a$	$\sqrt{\dfrac{5+\sqrt{5}}{10}}\,a$	$\dfrac{\sqrt{25+10\sqrt{5}}}{4}a^2$
5	Hexagon	$\dfrac{\sqrt{3}}{2}a$	a	$\dfrac{3\sqrt{3}}{2}a^2$
6	Octagon	$\dfrac{1+\sqrt{2}}{2}a$	$\dfrac{\sqrt{2+\sqrt{2}}}{2}a$	$2(1+\sqrt{2})a^2$
7	Enneagon	$\dfrac{5+2\sqrt{5}}{2}a$	$\dfrac{1+\sqrt{5}}{2}a$	$\dfrac{\sqrt{5+2\sqrt{5}}}{2}a^2$
8	Dodecagon	$\dfrac{2+\sqrt{3}}{2}a$	$\dfrac{3+\sqrt{3}}{\sqrt{6}}a$	$3(2+\sqrt{3})a^2$

M3.1.3. Circle

► **Some definitions and formulas.** A *circle* is the set of all points in the plane that are the same fixed distance R from a fixed point O (Fig. M3.12*a*). The distance R is called the *radius* of the circle and the point O is called its *center*. A plane figure bounded by a circle, including its interior, is called a *disk*. A segment connecting two points on a circle is called a *chord*. A chord passing through the center of a circle is called a *diameter* of the circle (Fig. M3.12*b*). The length of a diameter is $d = 2R$. A straight line that touches a circle at a single point is called a *tangent*, and the common point is called the *point of tangency* (Fig. M3.12*c*). A straight line that cuts a circle at two points, an extended chord, is called a

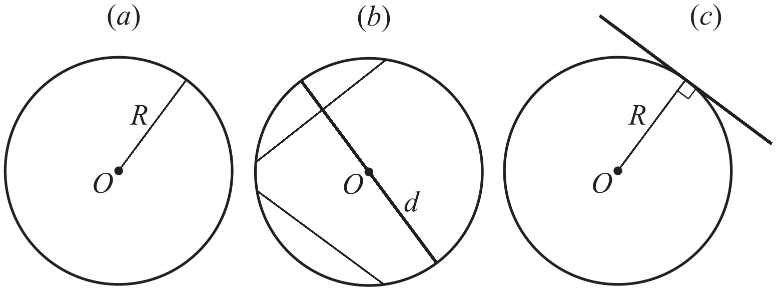

Figure M3.12. A circle (*a*), a diameter (*b*) and a tangent (*c*) of a circle.

secant. The angle formed by two radii is called a *central angle*. The angle formed by two chords with a common endpoint is called an *inscribed angle*.

Properties of circles and disks:

1. The circumference is $L = 2\pi R = \pi d = 2\sqrt{\pi S}$.
2. The area of a disk is $S = \pi R^2 = \frac{1}{4}\pi d^2 = \frac{1}{4}Ld$.
3. The diameter of a circle is a longest chord.
4. The diameter passing through the midpoint of a chord is perpendicular to the chord.
5. The radius drawn to the point of tangency is perpendicular to the tangent.
6. An inscribed angle is half the central angle subtended by the same chord, $\alpha = \frac{1}{2}\angle BOC$ (Fig. M3.13*a*).

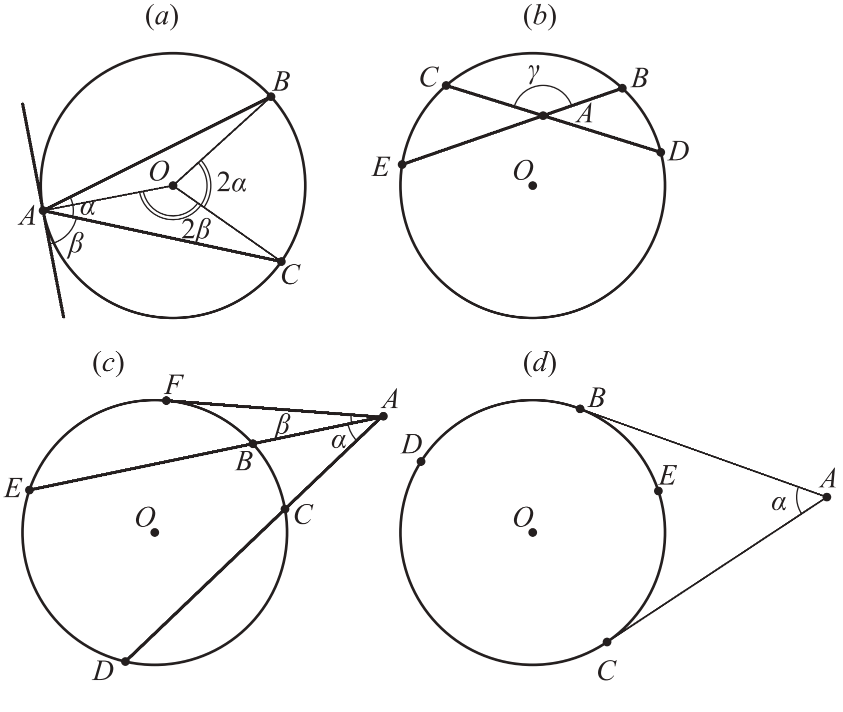

Figure M3.13. Properties of circles and disks.

7. The angle between a chord, AC, and the tangent to the circle at an endpoint, A, of the chord is equal to $\beta = \frac{1}{2}\angle AOC$ (Fig. M3.13*a*).
8. The angle between two chords, BE and CD, is $\gamma = \frac{1}{2}(\overset{\smile}{BC} + \overset{\smile}{ED})$ (Fig. M3.13*b*).

9. The angle between two secants, AD and AE, is $\alpha = \frac{1}{2}(\smile{DE} - \smile{BC})$ (Fig. M3.13*c*).
10. The angle between a secant, AE, and the tangent, AF, to the circle at a point, F, is equal to $\beta = \frac{1}{2}(\smile{FE} - \smile{BF})$ (Fig. M3.13*c*).
11. The angle between two tangents, AB and AC, is $\alpha = \frac{1}{2}(\smile{BDC} - \smile{BEC})$ (Fig. M3.13*d*).
12. If two chords, BE and CD, meet, then $AC \cdot AD = AB \cdot AE = R^2 - m^2$, $m = OA$ (Fig. M3.13*b*).
13. For secants, AE and AD, the relations $AC\cdot AD = AB\cdot AE = m^2 - R^2$ hold (Fig. M3.13*c*).
14. For a tangent, AF, and a secant, AD, the relation $AF^2 = AC \cdot AD$ holds (Fig. M3.13*c*).

► **Segment and sector.** A plane figure bounded by two radii and one of the subtended arcs is called a (*circular*) *sector*. A plane figure bounded by an arc and the corresponding chord is called a *segment* (Fig. M3.14*a*). If R is the radius of the circle, l is the arc length, a is the chord length, α is the central angle (in degrees), and h is the height of the segment, then the following relations hold:

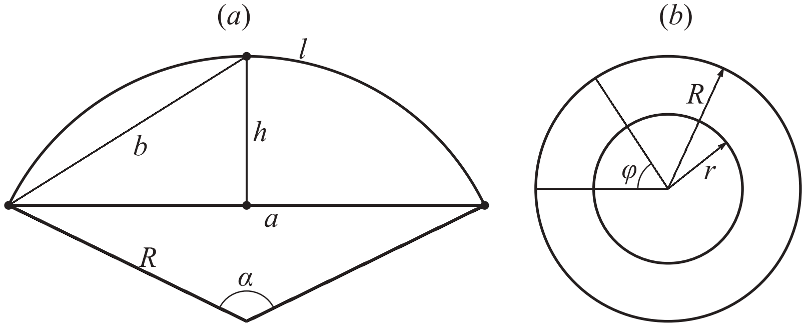

Figure M3.14. A segment (*a*) and an annulus (*b*).

$$
\begin{aligned}
a &= 2\sqrt{2hR - h^2} = 2R\sin\frac{\alpha}{2},\\
h &= R - \sqrt{R^2 - \frac{a^2}{4}} = R\left(1 - \cos\frac{\alpha}{2}\right) = \frac{a}{2}\tan\frac{\alpha}{4},\\
l &= \frac{2\pi R\alpha}{360} \approx 0.01745\, R\alpha.
\end{aligned}
\qquad \text{(M3.1.3.1)}
$$

The area of a circular sector is given by the formula

$$S = \frac{lR}{2} = \frac{\pi R^2\alpha}{360} \approx 0.00873\, R^2\alpha, \qquad \text{(M3.1.3.2)}$$

and the area of a segment not equal to a half-disk is given by

$$S_1 = \frac{\pi R^2\alpha}{360} \pm S_\Delta, \qquad \text{(M3.1.3.3)}$$

where S_Δ is the area of the triangle with vertices at the center of the disk and at the endpoints of the radii bounding the corresponding sector. One takes the minus sign for $\alpha < 180$ and the plus sign for $\alpha > 180$.

The arc length and the area of a segment can be found by the approximate formulas

$$\begin{aligned} &l \approx \frac{8b-a}{3}, \quad l \approx \sqrt{a^2 + \frac{16h^2}{3}},\\ &S_1 \approx \frac{h(6a+8b)}{15}, \end{aligned} \tag{M3.1.3.4}$$

where b is the chord of the half-segment (see Fig. M3.14a).

► **Annulus.** An *annulus* is a plane figure bounded by two concentric circles of distinct radii (Fig. M3.14b). Let R be the outer radius of an annulus (the radius of the outer bounding circle), and let r be the inner radius (the radius of the inner bounding circle). Then the area of the annulus is given by the formula

$$S = \pi(R^2 - r^2) = \frac{\pi}{4}(D^2 - d^2) = 2\pi\rho\delta, \tag{M3.1.3.5}$$

where $D = 2R$ and $d = 2r$ are the outer and inner diameters, $\rho = \frac{1}{2}(R+r)$ is the midradius, and $\delta = R - r$ is the width of the annulus.

The area of the part of the annulus contained in a sector of central angle φ, given in degrees (see Fig. M3.14b), is given by the formula

$$S = \frac{\pi\varphi}{360}(R^2 - r^2) = \frac{\pi\varphi}{1440}(D^2 - d^2) = \frac{\pi\varphi}{180}\rho\delta. \tag{M3.1.3.6}$$

M3.2. Solid Geometry

M3.2.1. Straight Lines, Planes, and Angles in Space

► **Mutual arrangement of straight lines and planes.**

1°. Two distinct straight lines lying in a single plane either have exactly one point of intersection or do not meet at all. In the latter case, they are said to be *parallel*. If two straight lines do not lie in a single plane, then they are called *skew lines*.

The angle between skew lines is determined as the angle between lines parallel to them and lying in a single plane (Fig. M3.15a). The distance between skew lines is the length of the straight line segment that meets both lines and is perpendicular to them.

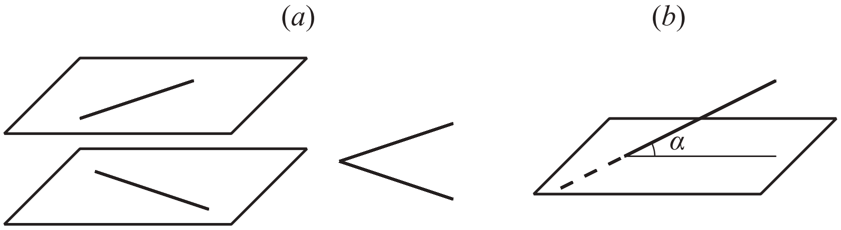

Figure M3.15. The angle between skew lines (a). The angle between a line and a plane (b).

2°. Two distinct planes either intersect in a straight line or do not have common points. In the latter case, they are said to be *parallel*. Coinciding planes are also assumed to be parallel. If two planes are perpendicular to a single straight line or each of them contains a pair of intersecting straight lines parallel to the corresponding lines in the other pair, then the planes are parallel.

3°. A straight line either entirely lies in the plane, meets the plane at a single point, or has no common points with the plane. In the last case, the line is said to be *parallel* to the plane.

The angle between a straight line and a plane is equal to the angle between the line and its projection onto the plane (Fig. M3.15b). If a straight line is perpendicular to two intersecting straight lines on a plane, then it is perpendicular to each line on the plane, i.e., *perpendicular to the plane*.

► Polyhedral angles.

1°. A *dihedral angle* is a figure in space formed by two half-planes issuing from a single straight line as well as the part of space bounded by these half-planes. The half-planes are called the *faces* of the dihedral angle, and their common straight line is called the *edge*. A dihedral angle is measured by its linear angle ABC (Fig. M3.16a), i.e., by the angle between the perpendiculars raised to the edge DE of the dihedral angle in both planes (*faces*) at the same point.

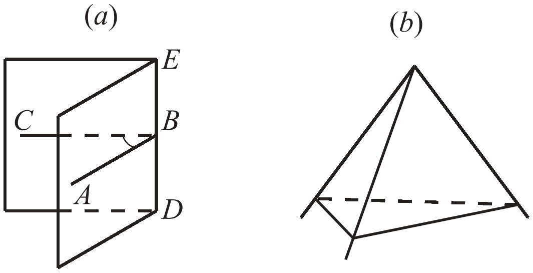

Figure M3.16. A dihedral (a) and a trihedral (b) angle.

2°. A part of space bounded by an infinite triangular pyramid is called a *trihedral angle* (Fig. M3.16b). The faces of this pyramid are called the *faces* of the trihedral angle, and the vertex of the pyramid is called the *vertex of a trihedral angle*. The rays in which the faces intersect are called the *edges* of a trihedral angle. The edges form *face angles*, and the faces form the dihedral angles of the trihedral angle. As a rule, one considers trihedral angles with dihedral angles less than π (or 180°), i.e., convex trihedral angles. Each face angle of a convex trihedral angle is less than the sum of the other two face angles and greater than their difference.

Two trihedral angles are equal if one of the following conditions is satisfied:

1. Two face angles, together with the included dihedral angle, of the first trihedral angle are equal to the respective parts (arranged in the same order) of the second trihedral angle.
2. Two dihedral angles, together with the included face angle, of the first trihedral angle are equal to the respective parts (arranged in the same order) of the second trihedral angle.
3. The three face angles of the first trihedral angle are equal to the respective face angles (arranged in the same order) of the second trihedral angle.
4. The three dihedral angles of the first trihedral angle are equal to the respective dihedral angles (arranged in the same order) of the second trihedral angle.

3°. A *polyhedral angle* $OABCDE$ (Fig. M3.17a) is formed by several planes (*faces*) having a single common point (the *vertex*) and successively intersecting along straight lines OA, OB, $\ldots$, OE (the *edges*). Two edges belonging to the same face form a *face angle* of the polyhedral angle, and two neighboring faces form a *dihedral angle*.

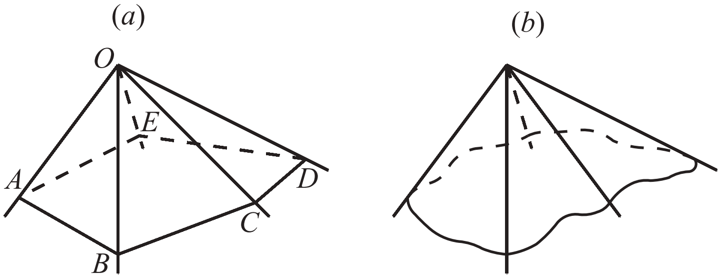

Figure M3.17. A polyhedral (*a*) and a solid (*b*) angle.

Polyhedral angles are equal (*congruent*) if one can be transformed into the other by translations and rotations. For polyhedral angles to be congruent, the corresponding parts (face and dihedral angles) must be equal.

A convex polyhedral angle lies entirely on one side of each of its faces. The sum $\angle AOB + \angle BOC + \cdots + \angle EOA$ of face angles (Fig. M3.17*a*) of any convex polyhedral angle is less that 2π (or 360°).

4°. A *solid angle* is a part of space bounded by straight lines issuing from a single point (vertex) to all points of some closed curve (Fig. M3.17*b*). Trihedral and polyhedral angles are special cases of solid angles. A solid angle is measured by the area cut by the solid angle on the sphere of unit radius centered at the vertex. Solid angles are measured in steradians. The entire sphere forms a solid angle of 4π steradians.

M3.2.2. Polyhedra

► **General concepts.** A *polyhedron* is a closed object formed by intersecting planes. In other words, a polyhedron is a set of finitely many plane polygons satisfying the following conditions:

1. Each side of each polygon is simultaneously a side of a unique other polygon, which is said to be adjacent to the first polygon (via this side).
2. From each of the polygons forming a polyhedron, one can reach any other polygon by successively passing to adjacent polygons.

These polygons are called the *faces*, their sides are called the *edges*, and their vertices are called the *vertices* of a polyhedron.

A polyhedron is said to be *convex* if it lies entirely on one side of the plane of any of its faces; if a polyhedron is convex, then so are its faces.

EULER'S THEOREM. *If the number of vertices in a convex polyhedron is v, the number of edges is e, and the number of faces is f, then $v + f - e = 2$.*

► **Prism. Parallelepiped.**

1°. An n-sided *prism* is a polyhedron in which two faces are equal n-gons (the *base faces*) that lie on parallel planes and have respectively parallel sides, and the remaining n faces (*joining* or *lateral faces*) are parallelograms; see Fig. M3.18*a*. A *right* prism is a prism in which the lateral faces are perpendicular to the base faces; otherwise it is an *oblique* prism. A right prism is said to be *regular* if its base faces are regular polygons.

If l is the lateral edge length, S is the area of the base face, H is the height of the prism (perpendicular distance between the planes of the bases), P_{sec} is the perimeter of a normal

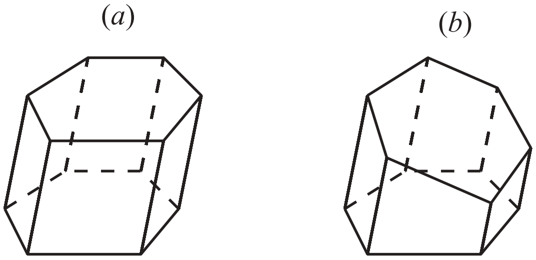

Figure M3.18. A prism (*a*) and a truncated prism (*b*).

section, one perpendicular to a lateral edge, and $S_{\rm sec}$ is the area of a normal section, then the area of the lateral surface $S_{\rm lat}$ and the volume V of the prism are given by the formulas

$$\begin{aligned} S_{\rm lat} &= P_{\rm sec}l \\ V &= SH = S_{\rm sec}l. \end{aligned} \tag{M3.2.2.1}$$

The portion of a prism between one of the bases and a plane nonparallel to it is called a *truncated prism* (Fig. M3.18*b*). The volume of a truncated prism is

$$V = LS_1, \tag{M3.2.2.2}$$

where L is the length of the segment connecting the centroids of the base faces and S_1 is the area of the section of the prism by a plane perpendicular to this segment.

The volume of a truncated regular prism (its base being a regular n-gon) is expressed as

$$V = S_{\rm sec}\frac{l_1 + l_2 + \cdots + l_n}{n},$$

where $S_{\rm sec}$ is the area of a normal section and l_1, l_2, …, l_n are the lengths of the lateral edges.

2°. A prism whose bases are parallelograms is called a *parallelepiped*. All four diagonals in a parallelepiped intersect at a single point and bisect each other (Fig. M3.19*a*). A parallelepiped is said to be *rectangular* if it is a right prism and its base faces are rectangles. In a rectangular parallelepiped, all diagonals are equal (Fig. M3.19*b*).

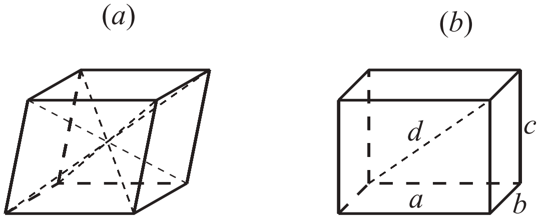

Figure M3.19. A parallelepiped (*a*) and a rectangular parallelepiped (*b*).

If a, b, and c are the lengths of the edges of a rectangular parallelepiped, then the diagonal d can be determined by the formula $d^2 = a^2 + b^2 + c^2$. The volume of a rectangular parallelepiped is given by the formula $V = abc$, and the lateral surface area is $S_{\rm lat} = PH$, where P is the perimeter of the base face.

3°. A rectangular parallelepiped all of whose edges are equal ($a = b = c$) is called a *cube*. The diagonal of a cube is given by the formula $d^2 = 3a^2$. The volume of the cube is $V = a^3$, and the lateral surface area is $S_{\rm lat} = 4a^2$.

▶ Pyramid, obelisk, and wedge.

1°. A *pyramid* is a polyhedron in which one face (the *base* of the pyramid) is an arbitrary polygon and the other (*lateral*) faces are triangles with a common vertex, called the *apex* of the pyramid (Fig. M3.20*a*). The base of an n*-sided* pyramid is an n-gon. The perpendicular through the apex to the base of a pyramid is called the *altitude* (*height*) of the pyramid.

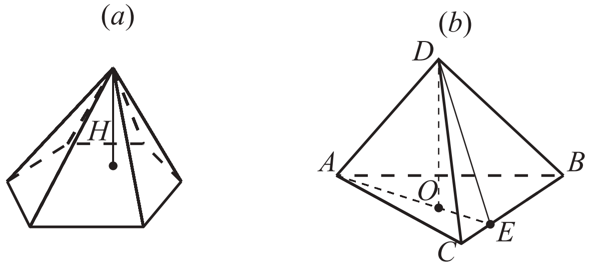

Figure M3.20. A pyramid (*a*). The altitude DO, the plane DAE, and the side BC in a triangular pyramid (*b*).

The volume of a pyramid is given by the formula

$$V = \frac{1}{3}SH, \qquad \text{(M3.2.2.3)}$$

where S is the area of the base and H is the altitude of the pyramid.

If DO is the altitude of the pyramid $ABCD$ and $DA \perp BC$, then the plane DAE is perpendicular to BC (Fig. M3.20*b*).

If the pyramid is cut by a plane (Fig. M3.21*a*) parallel to the base, then

$$\begin{gathered}\frac{SA_1}{A_1A} = \frac{SB_1}{B_1B} = \cdots = \frac{SO_1}{O_1O},\\ \frac{S_{ABCDEF}}{S_{A_1B_1C_1D_1E_1F_1}} = \left(\frac{SO}{SO_1}\right)^2,\end{gathered} \qquad \text{(M3.2.2.4)}$$

where SO is the altitude of the pyramid.

The altitude of a *triangular pyramid* passes through the orthocenter of its base if and only if all pairs of opposite edges of the pyramid are perpendicular.

Given the length of the edges, $DA = a$, $DB = b$, $DC = c$, $BC = p$, $AC = q$, and $AB = r$, of a triangular pyramid (Fig. M3.21*b*), its volume can be found from the relation

$$V^2 = \frac{1}{288}\begin{vmatrix} 0 & r^2 & q^2 & a^2 & 1\\ r^2 & 0 & p^2 & b^2 & 1\\ q^2 & p^2 & 0 & c^2 & 1\\ a^2 & b^2 & c^2 & 0 & 1\\ 1 & 1 & 1 & 1 & 0 \end{vmatrix}, \qquad \text{(M3.2.2.5)}$$

where the right-hand side contains a determinant.

A pyramid is said to be *regular* if its base is a regular n-gon and the altitude passes through the center of the base. The altitude (dropped from the apex) of a lateral face is called the *apothem* of a regular pyramid. For a regular pyramid, the lateral surface area is

$$S_{\text{lat}} = \frac{1}{2}Pl, \qquad \text{(M3.2.2.6)}$$

where P is the perimeter of the base and l is the apothem.

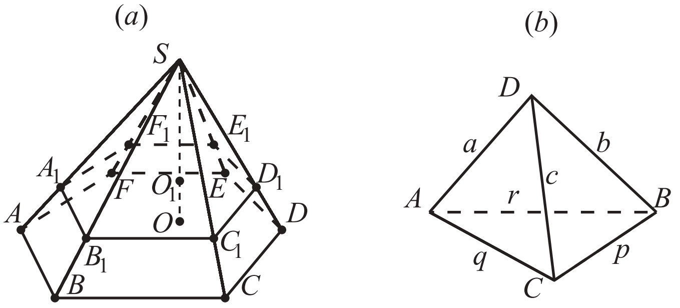

Figure M3.21. The original pyramid and a pyramid cut off by a plane (*a*). A triangular pyramid (*b*).

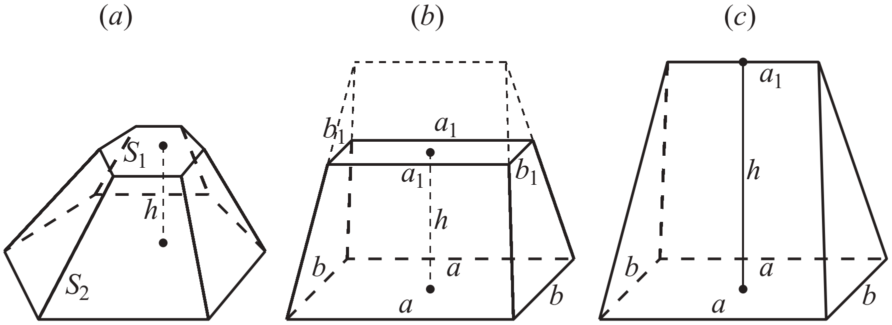

Figure M3.22. A frustum of a pyramid (*a*), an obelisk (*b*), and a wedge (*c*).

2°. If a pyramid is cut by a plane parallel to the base, then it splits into two parts: a pyramid similar to the original pyramid and the *frustum* (Fig. M3.22*a*). The volume of the frustum is

$$V = \frac{1}{3}h(S_1 + S_2 + \sqrt{S_1S_2}\,) = \frac{1}{3}hS_2\left(1 + \frac{a}{A} + \frac{a^2}{A^2}\right), \qquad \text{(M3.2.2.7)}$$

where S_1 and S_2 are the areas of the bases, a and A are two respective sides of the bases, and h is the altitude (the perpendicular distance between the bases).

For a regular frustum, the lateral surface area is

$$S_{\text{lat}} = \frac{1}{2}(P_1 + P_2)l, \qquad \text{(M3.2.2.8)}$$

where P_1 and P_2 are the perimeters of the bases and l is the altitude of the lateral face.

3°. A hexahedron whose bases are rectangles lying in parallel planes and whose lateral faces form equal angles with the base, but do not meet at a single point, is called an *obelisk* (Fig. M3.22*b*). If a, b and a_1, b_1 are the sides of the bases and h is the altitude, then the volume of the hexahedron is

$$V = \frac{h}{6}[(2a + a_1)b + (2a_1 + a)b_1]. \qquad \text{(M3.2.2.9)}$$

4°. A pentahedron whose base is a rectangle and whose lateral faces are isosceles triangles and isosceles trapezoids is called a *wedge* (Fig. M3.22*c*). The volume of the wedge is

$$V = \frac{h}{6}(2a + a_1)b. \qquad \text{(M3.2.2.10)}$$

► **Regular polyhedra.** A polyhedron is said to be *regular* if all of its faces are equal regular polygons and all polyhedral angles are equal to each other. There exist five regular polyhedra (Fig. M3.23), whose properties are given in Table M3.4.

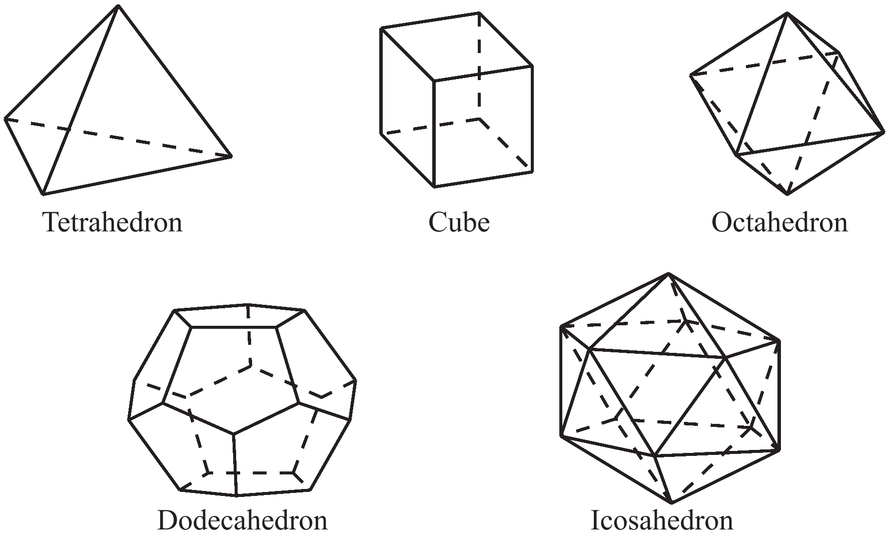

Figure M3.23. Five regular polyhedra.

TABLE M3.4
Regular polyhedra (a is the edge length).

No.	Name	Number of faces and their shapes	Number of vertices	Number of edges	Total surface area	Volume
1	Tetrahedron	4 triangles	4	6	$a^2\sqrt{3}$	$\frac{a^3\sqrt{2}}{12}$
2	Cube	6 squares	8	12	$6a^2$	a^3
3	Octahedron	8 triangles	6	12	$2a^2\sqrt{3}$	$\frac{a^3\sqrt{2}}{3}$
4	Dodecahedron	12 pentagons	20	30	$3a^2\sqrt{25+10\sqrt{5}}$	$\frac{a^3}{4}(15+7\sqrt{5})$
5	Icosahedron	20 triangles	12	30	$3a^2\sqrt{3}$	$\frac{5a^3}{12}(3+\sqrt{5})$

M3.2.3. Solids Formed by Revolution of Lines

► **Cylinder.** A *cylindrical surface* is a surface in space swept by a straight line (the *generator*) moving parallel to a given direction along some curve (the *directrix*) (Fig. M3.24*a*).

1°. A solid bounded by a closed cylindrical surface and two planes is called a *cylinder*; the planes are called the *bases* of the cylinder (Fig. M3.24*b*).

If P is the perimeter of the base, P_{sec} is the perimeter of the section perpendicular to the generator, S_{sec} is the area of this section, S_{bas} is the area of the base, and l is the length of the generator, then the lateral surface area S_{lat} and the volume V of the cylinder are given by the formulas

$$\begin{aligned} S_{\text{lat}} &= PH = P_{\text{sec}}l, \\ V &= S_{\text{bas}}H = S_{\text{sec}}l. \end{aligned} \qquad \text{(M3.2.3.1)}$$

In a *right* cylinder, the bases are perpendicular to the generator. In particular, if the bases are disks, then one speaks of a *right circular cylinder*. The volume, the lateral surface

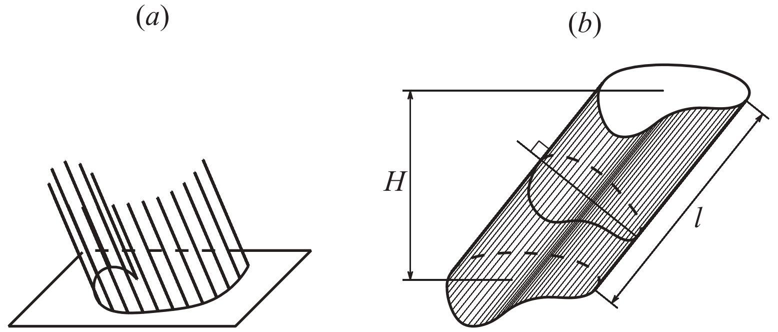

Figure M3.24. A cylindrical surface (*a*). A cylinder (*b*).

area, and the total surface area of a right circular cylinder are given by the formulas

$$\begin{aligned} V &= \pi R^2 H, \\ S_{\text{lat}} &= 2\pi R H, \\ S &= 2\pi R(R+H), \end{aligned} \tag{M3.2.3.2}$$

where R is the radius of the base.

A right circular cylinder is also called a *round cylinder*, or simply a *cylinder*.

2°. The part of a cylinder cut by a plane nonparallel to the base is called a *truncated cylinder* (Fig. M3.25*a*).

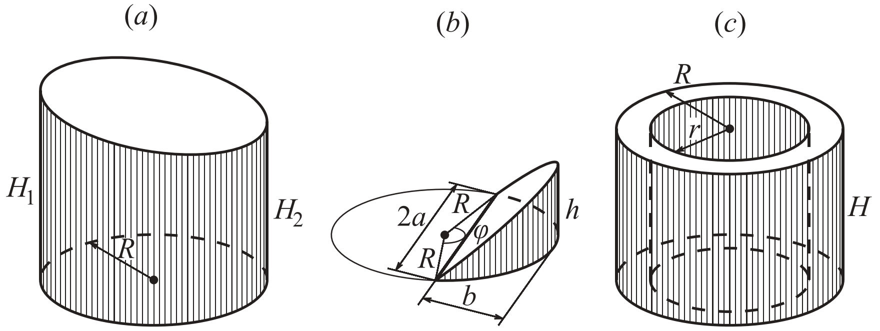

Figure M3.25. A truncated cylinder (*a*), a “hoof” (*b*), and a cylindrical tube (*c*).

The volume, the lateral surface area, and the total surface area of a truncated cylinder are given by the formulas

$$\begin{aligned} V &= \pi R^2 \frac{H_1+H_2}{2}, \\ S_{\text{lat}} &= \pi R(H_1+H_2), \\ S &= \pi R\left[H_1+H_2+R+\sqrt{R^2+\left(\frac{H_2-H_1}{2}\right)^2}\,\right], \end{aligned} \tag{M3.2.3.3}$$

where H_1 and H_2 are the maximal and minimal generators.

3°. A *segment of a round cylinder (a "hoof")* is a portion of the cylinder cut by a plane that is nonparallel to the base and intersects it. If R is the radius of the cylindrical segment, h is the height of the "hoof," and b is its width (for the other notation, see Fig. M3.25*b*), then the volume V and the lateral surface area S_{lat} of the "hoof" can be determined by the formulas

$$\begin{aligned} V &= \frac{h}{3b}\big[a(3R^2-a^2)+3R^2(b-R)\alpha\big] = \frac{hR^3}{b}\left(\sin\alpha-\frac{\sin^3\alpha}{3}-\alpha\cos\alpha\right), \\ S_{\text{lat}} &= \frac{2\pi R}{b}[(b-R)\alpha+a], \end{aligned} \tag{M3.2.3.4}$$

where $\alpha=\frac{1}{2}\varphi$ is measured in radians.

4°. A solid bounded by two closed cylindrical surfaces and two planes is called a *cylindrical tube*; the planes are called the bases of the tube. The volume of a round cylindrical tube (Fig. M3.25*c*) is

$$V=\pi H(R^2-r^2)=\pi H\delta(2R-r)=\pi H\delta(2r+\delta)=2\pi H\delta\rho, \tag{M3.2.3.5}$$

where R and r are the outer and inner radii, $\delta=R-r$ is the thickness, $\rho=\frac{1}{2}(R+r)$ is the midradius, and H is the height of the pipe.

► **Conical surface. Cone. Frustum of cone.** A *conical surface* is the union of straight lines (*generators*) passing through a fixed point (the *apex*) in space and any point of some space curve (the *directrix*) (Fig. M3.26*a*).

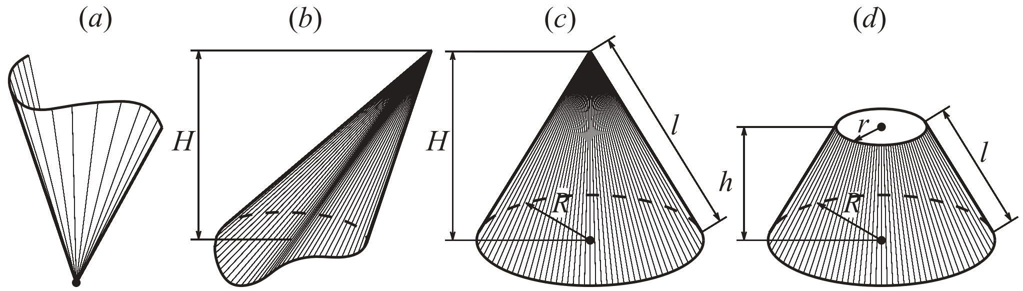

Figure M3.26. Conical surface (*a*). A cone (*b*), a right circular cone (*c*), and a frustum of a cone (*d*).

1°. A solid bounded by a conical surface with closed directrix and a plane is called a *cone*; the plane is the base of the cone (Fig. M3.26*b*). The volume of an arbitrary cone is given by the formula

$$V=\frac{1}{3}HS_{\text{bas}}, \tag{M3.2.3.6}$$

where H is the altitude of the cone and S_{bas} is the area of the base.

A *right circular cone* (Fig. M3.26*c*) has a disk as the base, and its vertex is projected onto the center of the disk. If l is the length of the generator and R is the radius of the base, then the volume, the lateral surface area, and the total surface area of the right circular cone are given by the formulas

$$\begin{aligned} V &= \frac{1}{3}\pi R^2 H, \\ S_{\text{lat}} &= \pi R l = \pi R\sqrt{R^2+H^2}, \\ S &= \pi R(R+l). \end{aligned} \tag{M3.2.3.7}$$

2°. If a cone is cut by a plane parallel to the base, then we obtain a *frustum of a cone* (Fig. M3.26*d*). The length l of the generator, the volume V, the lateral surface area S_{lat}, and the total surface area S of the frustum of a right circular cone are given by the formulas

$$\begin{aligned} l &= \sqrt{h^2 + (R-r)^2}, \\ V &= \frac{\pi h}{3}(R^2 + r^2 + Rr), \\ S_{\text{lat}} &= \pi l(R+r), \\ S &= \pi[l(R+r) + R^2 + r^2], \end{aligned} \qquad \text{(M3.2.3.8)}$$

where r is the radius of the upper base and h is the altitude of the frustum of a cone.

► Sphere. Spherical parts. The torus.

1°. A *sphere* is the set of all points in space that are the same distance R from a fixed point O (Fig. M3.27*a*). The distance R is called the *radius* of the sphere and the point O is called its *center*. A straight line segment that passes through the center of a sphere and whose endpoints are on the sphere is called a *diameter* of the sphere. A solid formed by a sphere together with its interior is called a *ball*. Any section of the sphere by a plane is a circle. The section of the sphere by a plane passing through its center is called a *great circle* of radius R. There exists exactly one great circle passing through two arbitrary points on the sphere that are not antipodal (i.e., are not the opposite endpoints of a diameter); the smaller arc of this great circle is the shortest distance on the sphere between these points. The surface area S of a sphere and the volume V of the ball bounded by the sphere are given by

$$\begin{aligned} S &= 4\pi R^2 = \pi D^2 = \sqrt[3]{36\pi V^2}, \\ V &= \frac{4\pi R^3}{3} = \frac{\pi D^3}{6} = \frac{1}{6}\sqrt{\frac{S^3}{\pi}}, \end{aligned} \qquad \text{(M3.2.3.9)}$$

where $D = 2R$ is the diameter of the sphere.

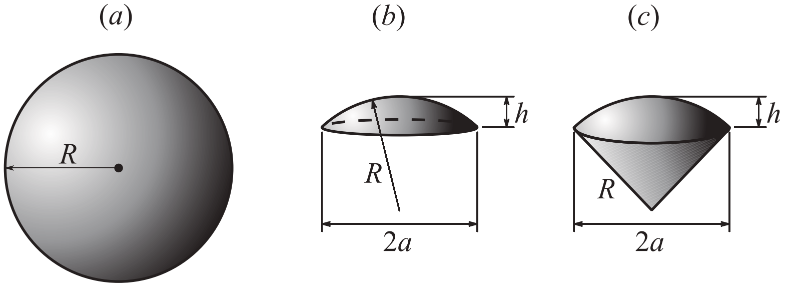

Figure M3.27. A sphere (*a*), a spherical cap (*b*), and a spherical sector (*c*).

2°. A portion of a ball cut from it by a plane is called a *spherical cap* (Fig. M3.27*b*). The width a (base radius), the area S_{lat} of the curved surface, the total surface area S, and the volume V of a spherical cap can be found from the formulas

$$\begin{aligned} a^2 &= h(2R-h), \\ S_{\text{lat}} &= 2\pi Rh = \pi(a^2 + h^2), \\ S &= S_{\text{lat}} + \pi a^2 = \pi(2Rh + a^2) = \pi(h^2 + 2a^2), \\ V &= \frac{\pi h}{6}(3a^2 + h^2) = \frac{\pi h^2}{3}(3R-h), \end{aligned} \qquad \text{(M3.2.3.10)}$$

where R and h are the radius and the height of the spherical cap.

3°. A portion of a ball bounded by the curved surface of a spherical cap and the conical surface whose base is the base of the cap and whose vertex is the center of the ball is called a *spherical sector* (Fig. M3.27*c*). The total surface area S and the volume V of a spherical sector are given by the formulas

$$\begin{aligned} S &= \pi R(2h + a), \\ V &= \frac{2}{3}\pi R^2 h, \end{aligned} \tag{M3.2.3.11}$$

where a is the width of the spherical cap, h is its height, and R is the radius of the sector.

4°. A portion of a ball contained between two parallel plane secants is called a *spherical segment* (Fig. M3.28*a*). The curved surface of a spherical segment is called a *spherical zone*, and the plane circular surfaces are the *bases* of a spherical segment. The radius R of the ball, the radii a and b of the bases, and the height h of a spherical segment satisfy the relation

$$R^2 = a^2 + \left(\frac{a^2 - b^2 - h^2}{2h}\right)^2. \tag{M3.2.3.12}$$

The curved surface area S_{lat}, the total surface area S, and the volume V of a spherical segment are given by the formulas

$$\begin{aligned} S_{\text{lat}} &= 2\pi Rh, \\ S &= S_{\text{lat}} + \pi(a^2 + b^2) = \pi(2Rh + a^2 + b^2), \\ V &= \frac{\pi h}{6}(3a^2 + 3b^2 + h^2). \end{aligned} \tag{M3.2.3.13}$$

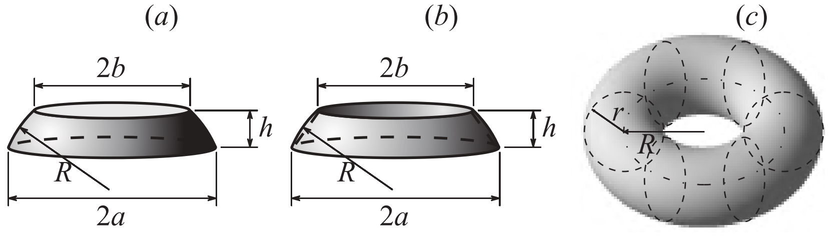

Figure M3.28. A spherical segment (*a*) and a spherical segment without the truncated cone inscribed in it (*b*). A torus (*c*).

If V_1 is the volume of the truncated cone inscribed in a spherical segment (Fig. M3.28*b*) and l is the length of its generator, then $V - V_1 = \frac{\pi h l^2}{6}$.

5°. A *torus* is a surface generated by revolving a circle about an axis coplanar with the circle but not intersecting it (Fig. M3.28*c*). If r is the radius of the circle being rotated and R is the distance from its center to the axis of revolution ($R > r$), then the surface area and the volume of the torus are given by

$$\begin{aligned} S &= 4\pi^2 Rr = \pi^2 Dd, \\ V &= 2\pi^2 Rr^2 = \frac{\pi^2 Dd^2}{4}, \end{aligned}$$

where $d = 2r$ and $D = 2R$ are the diameters of the generating circle and the circle of revolution.

Chapter M4

Analytic Geometry

M4.1. Points, Segments, and Coordinate Plane

M4.1.1. Cartesian and Polar Coordinates on Plane

► **Rectangular Cartesian coordinates in the plane.** A *rectangular Cartesian coordinate system* consists of two mutually perpendicular directed lines, called *coordinate axes*, each treated as a number line (see Subsection M6.1.1). The point of intersection of the axes is called the *origin* and usually labeled with the letter O, while the axes themselves are called the *coordinate axes*. As a rule, one of the coordinate axes is horizontal, directed from left to right, and called the *abscissa axis*. The other axis is vertical, directed upwards, and called the *ordinate axis*. The two axes are usually denoted by X or OX and Y or OY, respectively, and the coordinate system itself is denoted by XY or OXY. The two coordinate axes divide the plane into four parts, which are called *quadrants* and numbered I, II, III, and IV counterclockwise as shown in Fig. M4.1.

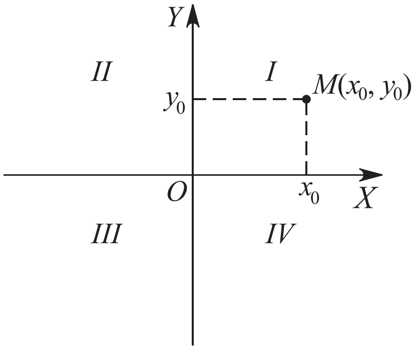

Figure M4.1. A rectangular Cartesian coordinate system.

Each point M in the plane is uniquely defined by a pair of real numbers $(x_0,\ y_0)$, called its *coordinates*, which specify its projections onto the X- and Y-axes. The numbers x_0 and y_0 are called, respectively, the *abscissa* and the *ordinate* of the point M.

Remark. Strictly speaking, the coordinate system introduced above is a *right rectangular Cartesian coordinate system*. A *left rectangular Cartesian coordinate system* can, for example, be obtained by changing the direction of one of the axes. A right rectangular Cartesian coordinate system is usually called simply a Cartesian coordinate system.

If A and B are two points in the plane, then the length of the segment AB will be denoted $|AB|$.

► **Polar coordinates.** A *polar coordinate system* is determined by a point O called the *pole*, a ray OA issuing from this point, which is called the *polar axis*, a scale segment for measuring lengths, and the positive sense of rotation around the pole. Usually, the counterclockwise sense is assumed to be positive (see Fig. M4.2*a*).

The position of each point M on the plane is determined by two *polar coordinates*, the *polar radius* $\rho = |OM|$ and the *polar angle* $\theta = \angle AOM$ (the values of the angle θ are defined up to an additive term $2\pi n$, where n is an integer). To be definite, one usually assumes that $0 \le \theta \le 2\pi$ or $-\pi \le \theta \le \pi$. The polar radius of the pole is zero, and its polar angle does not have any definite value.

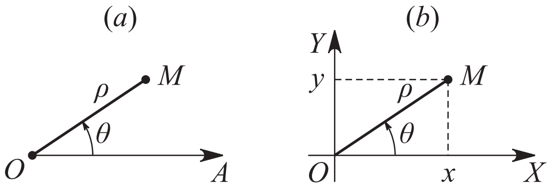

Figure M4.2. A polar coordinate system (*a*). Relationship between Cartesian and polar coordinates (*b*).

► **Relationship between Cartesian and polar coordinates.** Suppose that M is an arbitrary point in the plane, (x, y) are its rectangular Cartesian coordinates, and (ρ, θ) are its polar coordinates (see Fig. M4.2*b*). The transformation from one coordinate system to the other is expressed by the formulas

$$\begin{aligned} x &= \rho\cos\theta, \\ y &= \rho\sin\theta \end{aligned} \qquad \text{or} \qquad \begin{aligned} \rho &= \sqrt{x^2+y^2}, \\ \tan\theta &= y/x, \end{aligned} \tag{M4.1.1.1}$$

where the polar angle θ is determined with regard to the quadrant where the point M lies.

Example. Let us find the polar coordinates ρ, θ $(0 \le \theta \le 2\pi)$ of the point M whose Cartesian coordinates are $x = -3$, $y = -3$.

From formulas (M4.1.1.1), we obtain $\rho = \sqrt{(-3)^2 + (-3)^2} = 3\sqrt{2}$ and $\tan\theta = \frac{-3}{-3} = 1$. Since the point M lies in the third quadrant, we have $\theta = \arctan 1 + \pi = \frac{5}{4}\pi$.

M4.1.2. Distance Between Points. Division of Segment in Given Ratio. Area of a Polygon

► **Distance between points on plane.** The distance d between two arbitrary points $A_1(x_1, y_1)$ and $A_2(x_2, y_2)$ on the plane is given by the formula

$$d = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2},$$

where x and y with the respective subscripts are the Cartesian coordinates of these points, and by the formula

$$d = \sqrt{\rho_1^2 + \rho_2^2 - 2\rho_1\rho_2\cos(\theta_2 - \theta_1)},$$

where ρ and θ with the respective subscripts are the polar coordinates of these points.

► **Angles between segments.** The angle β between arbitrary segments A_1A_2 and A_3A_4 joining the points $A_1(x_1, y_1)$, $A_2(x_2, y_2)$ and $A_3(x_3, y_3)$, $A_4(x_4, y_4)$, respectively, can be found from the relation

$$\cos\beta = \frac{(x_2 - x_1)(x_4 - x_3) + (y_2 - y_1)(y_4 - y_3)}{\sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2}\sqrt{(x_4 - x_3)^2 + (y_4 - y_3)^2}}.$$

► **Division of a segment in a given ratio.** Given two points, $A(x_1, y_1)$ and $B(x_2, y_2)$, and a number λ, the coordinates of the point $M(x, y)$ dividing the segment AB in the ratio $\lambda = |AM| : |MB|$ are expressed as

$$x = \frac{x_1 + \lambda x_2}{1 + \lambda}, \qquad y = \frac{y_1 + \lambda y_2}{1 + \lambda}. \tag{M4.1.2.1}$$

Example. Find the coordinates of the midpoint of a segment AB.

The midpoint of the segment corresponds to $\lambda = 1$. Substituting this value into (M4.1.2.1) gives $x = \dfrac{x_1 + x_2}{2}$, $y = \dfrac{y_1 + y_2}{2}$.

► **Area of a triangle.** The area S_3 of the triangle with vertices A_1, A_2, and A_3 is given by the formula

$$\begin{aligned} \pm S_3 &= \frac{1}{2}[(x_2 - x_1)(y_3 - y_1) - (x_3 - x_1)(y_2 - y_1)] \\ &= \frac{1}{2}\begin{vmatrix} x_2 - x_1 & y_2 - y_1 \\ x_3 - x_1 & y_3 - y_1 \end{vmatrix} = \frac{1}{2}\begin{vmatrix} x_1 & y_1 & 1 \\ x_2 & y_2 & 1 \\ x_3 & y_3 & 1 \end{vmatrix}, \end{aligned} \tag{M4.1.2.2}$$

where x and y with respective subscripts are the Cartesian coordinates of the vertices, and by the formula

$$\pm S_3 = \frac{1}{2}[\rho_1\rho_2 \sin(\theta_2 - \theta_1) + \rho_2\rho_3 \sin(\theta_3 - \theta_2) + \rho_3\rho_1 \sin(\theta_1 - \theta_3)], \tag{M4.1.2.3}$$

where ρ and θ with respective subscripts are the polar coordinates of the vertices. In formulas (M4.1.2.2) and (M4.1.2.3), one takes the plus sign if the vertices are numbered counterclockwise (see Fig. M4.3*a*) and the minus sign otherwise.

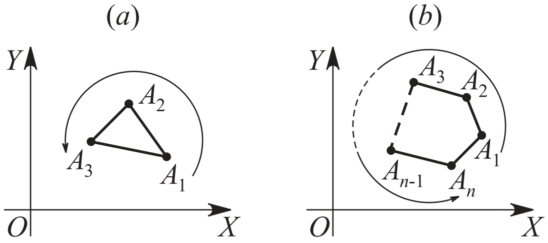

Figure M4.3. Area of a triangle (*a*) and of a polygon (*b*).

► **Area of a polygon.** The area S_n of the polygon with vertices $A_1, \ldots, A_n$ is given by the formula

$$\pm S_n = \frac{1}{2}[(x_1 - x_2)(y_1 + y_2) + (x_2 - x_3)(y_2 + y_3) + \cdots + (x_n - x_1)(y_n + y_1)], \tag{M4.1.2.4}$$

where x and y with respective subscripts are the Cartesian coordinates of the vertices, and by the formula

$$\pm S_n = \frac{1}{2}[\rho_1\rho_2 \sin(\theta_2 - \theta_1) + \rho_2\rho_3 \sin(\theta_3 - \theta_2) + \cdots + \rho_n\rho_1 \sin(\theta_1 - \theta_n)], \tag{M4.1.2.5}$$

where ρ and θ with respective subscripts are the polar coordinates of the vertices. In formulas (M4.1.2.4) and (M4.1.2.5), one takes the plus sign if the vertices are numbered counterclockwise (see Fig. M4.3*b*) and the minus sign otherwise.

Remark. One often says that formulas (M4.1.2.2)–(M4.1.2.5) express the *oriented area* of the corresponding figures.

M4.2. Straight Lines and Points on Plane

M4.2.1. Equations of Straight Lines on Plane

► **Equation of a curve.** Given a coordinate system, the set of all points in the plane can be treated as the set of various pairs of numbers x, y. Relations imposed upon x and y define subsets of the plane.

A line in the plane is usually defined using an equation relating the Cartesian coordinates x and y. An equation

$$F(x,y)=0$$

is an *equation of a curve in the plane* if the coordinates of all the points lying on the curve satisfy the equation and the coordinates of all those points that do not lie on the curve do not satisfy it.

Example 1. Derive an equation of the line all of whose points are equidistant from the points $A(0,2)$ and $B(4,-2)$.

Let $M(x,y)$ be a point that belongs to the line. For the distances to A and B, we have

$$\rho(A,M)=\sqrt{x^2+(y-2)^2},\qquad \rho(B,M)=\sqrt{(x-4)^2+(y+2)^2}.$$

It follows from the relation $\rho(A,M)=\rho(B,M)$ that $x^2+(y-2)^2=(x-4)^2+(y+2)^2$. Expanding and collecting similar terms yields $y=x-2$, which is an equation that determines a straight line.

Parametric equations of a curve on the plane have the form

$$x=\varphi(t),\qquad y=\psi(t),$$

where x and y are treated as the coordinates of some point M for each value of the *variable parameter* t.

► **Slope-intercept equation of a straight line.** The *slope-intercept equation of a straight line* in the rectangular Cartesian coordinate system OXY has the form

$$y=kx+b,\tag{M4.2.1.1}$$

where $k=\tan\varphi$ is the slope of the line and b is the y-intercept of the line, i.e., the signed distance from the point of intersection of the line with the ordinate axis to the origin. Equation (M4.2.1.1) is meaningful for any straight line that is not perpendicular to the abscissa axis (see Fig. M4.4*a*).

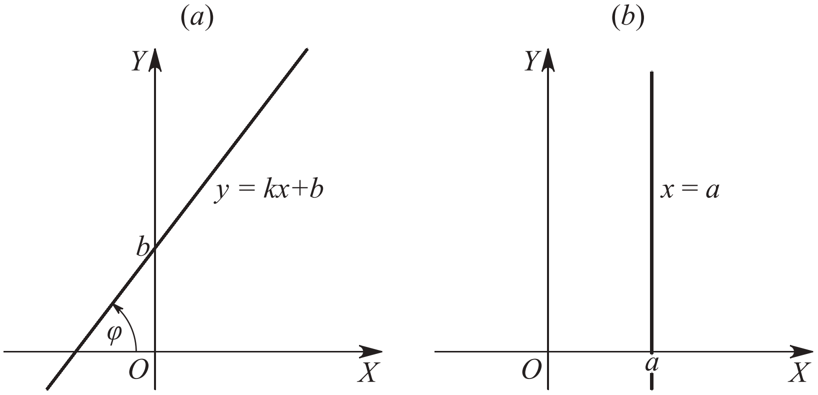

Figure M4.4. Straight lines on plane.

If a straight line is not perpendicular to the OX-axis, then its equation can be written as (M4.2.1.1), but if a straight line is perpendicular to the OX-axis, then its equation can be written as

$$x = a, \tag{M4.2.1.2}$$

where a is the abscissa of the point of intersection of this line with the OX-axis (see Fig. M4.4*b*).

For the slope of a straight line, we also have the formula

$$k = \frac{y_2 - y_1}{x_2 - x_1}, \tag{M4.2.1.3}$$

where $A_1(x_1, y_1)$ and $A_2(x_2, y_2)$ are two arbitrary points of the line.

► **Point-slope equation of a straight line.** In the rectangular Cartesian coordinate system OXY, the equation of a straight line with slope k passing through a point $A(x_1, y_1)$ has the form

$$y - y_1 = k(x - x_1). \tag{M4.2.1.4}$$

If we set $x_1 = 0$ and $y_1 = b$ in equation (M4.2.1.4), then we obtain equation (M4.2.1.1).

► **Equation of a straight line passing through two given points.** The equation of a straight line passing through two distinct points $A_1(x_1, y_1)$ and $A_2(x_2, y_2)$ has the form

$$\frac{x - x_1}{x_2 - x_1} = \frac{y - y_1}{y_2 - y_1} \qquad (x_1 \neq x_2,\ y_1 \neq y_2). \tag{M4.2.1.5}$$

If $x_1 = x_2$, this equation degenerates into $x = x_1$. If $y_1 = y_2$, the equation becomes $y = y_1$.

Example 2. Let us derive the equation of the straight line passing through the points $A_1(5, 1)$ and $A_2(7, 3)$. Substituting the coordinates of these points into formula (M4.2.1.5), we obtain

$$\frac{x - 5}{2} = \frac{y - 1}{2} \qquad \text{or} \qquad y = x - 4.$$

► **General equation of a straight line.** A linear equation of the form

$$Ax + By + C = 0 \qquad (A^2 + B^2 \neq 0) \tag{M4.2.1.6}$$

is called the *general equation of a straight line* in the rectangular Cartesian coordinate system OXY. In rectangular Cartesian coordinates, each straight line is determined by an equation of degree 1, and, conversely, each equation of degree 1 determines a straight line.

If $B \neq 0$, then equation (M4.2.1.6) can be written as (M4.2.1.1), where $k = -A/B$ and $b = -C/B$.

Special cases of equation (M4.2.1.6):

1. If $A = 0$ and $B \neq 0$, then the equation becomes $y = -C/B$ and determines a straight line parallel to the axis OX.
2. If $B = 0$ and $A \neq 0$, then the equation becomes $x = -C/A$ and determines a straight line parallel to the axis OY.
3. If $C = 0$, then the equation becomes $Ax + By = 0$ and determines a straight line passing through the origin.

► **General equation of a straight line passing through a given point.** In the rectangular Cartesian coordinate system OXY, the general equation of a straight line passing through a point $M(x_1, y_1)$ in the plane has the form

$$A(x - x_1) + B(y - y_1) = 0. \tag{M4.2.1.7}$$

► **Parametric equations of a straight line.** In the rectangular Cartesian coordinate system OXY, a straight line passing through a point $M(x_1, y_1)$ in the plane can be represented by the parametric equations

$$x = x_1 + At, \quad y = y_1 + Bt, \tag{M4.2.1.8}$$

where A and B are constants and t is a variable parameter.

A straight line passing through two points, $M_1(x_1, y_1)$ and $M_2(x_2, y_2)$, can be represented by the parametric equations

$$\begin{aligned} x &= x_1(1-t) + x_2 t, \\ y &= y_1(1-t) + y_2 t. \end{aligned} \tag{M4.2.1.9}$$

► **Intercept-intercept equation of a straight line.** The general equation of a straight line can be rewritten in the form

$$\frac{x}{a} + \frac{y}{b} = 1,$$

which is called the *intercept-intercept equation of a straight line*. The numbers a and b are the x- and y-intercepts of the straight line, i.e., the signed distances from the origin to the points at which the straight line crosses the coordinate axes (see Fig. M4.5).

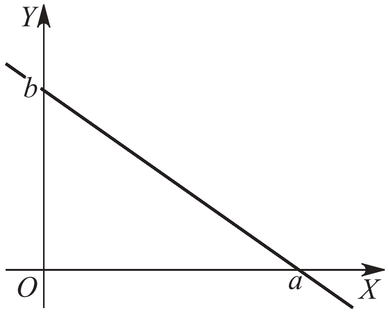

Figure M4.5. A straight line with intercept-intercept equation.

► **Equation of a pencil of straight lines.** The set of all straight lines passing through a fixed point M in the plane is called a *pencil of straight lines*, and the point M itself is called the *center of the pencil*. The equation determining all straight lines in the pencil is called the *equation of the pencil*.

1°. Given the Cartesian coordinates of the pencil center $M(x_1, y_1)$, then the equation of any straight line in the pencil has the form (M4.2.1.7), where A and B are arbitrary constants.

2°. If the equations of two straight lines in the pencil are known, $A_1x + B_1y + C_1 = 0$ and $A_2x + B_2y + C_2 = 0$, then the equation of the pencil can be written as

$$\alpha(A_1x + B_1y + C_1) + \beta(A_2x + B_2y + C_2) = 0,$$

where α and β are any numbers that are not simultaneously zero.

M4.2.2. Mutual Arrangement of Points and Straight Lines

► **Condition for three points to be collinear.** Suppose there are three distinct points, $M_1(x_1, y_1)$, $M_2(x_2, y_2)$, and $M_3(x_3, y_3)$, given in the Cartesian coordinate system OXY on the plane. They are collinear (lie on the same straight line) if and only if

$$\begin{vmatrix} x_1 & y_1 & 1 \\ x_2 & y_2 & 1 \\ x_3 & y_3 & 1 \end{vmatrix} = x_1y_2 + x_2y_3 + x_3y_1 - x_1y_3 - x_2y_1 - x_3y_2 = 0.$$

This condition reflects the fact that the area of the triangle with vertices at the above points is zero; cf. Eq. (M4.1.2.2).

► **Distance from a point to a straight line.** The distance d from a point $M(x_0, y_0)$ to a straight line given by the general equation $Ax + By + C = 0$ can be calculated as

$$d = \frac{|Ax_0 + By_0 + C|}{\sqrt{A^2 + B^2}}. \tag{M4.2.2.1}$$

Example 1. Let us find the distance from the point $M(2, 1)$ to the straight line $3x - 4y + 8 = 0$. We use formula (M4.2.2.1) to obtain

$$d = \frac{|3 \cdot 2 - 4 \cdot 1 + 8|}{\sqrt{3^2 + 4^2}} = \frac{10}{5} = 2.$$

► **Angle between two straight lines.**

1°. If two straight lines are given by the equations

$$y = k_1 x + b_1,$$
$$y = k_2 x + b_2,$$

where $k_1 = \tan\varphi_1$ and $k_2 = \tan\varphi_2$ are the slopes of the respective lines (see Fig. M4.6), the angle α between these straight lines is determined by the formula

$$\tan\alpha = \frac{k_2 - k_1}{1 + k_1 k_2} \qquad (k_1 k_2 \neq -1).$$

If $k_1 = k_2$, the straight lines are *parallel* ($\alpha = 0$).

If $k_1 k_2 = -1$, the straight lines are *perpendicular* ($\alpha = \frac{1}{2}\pi$).

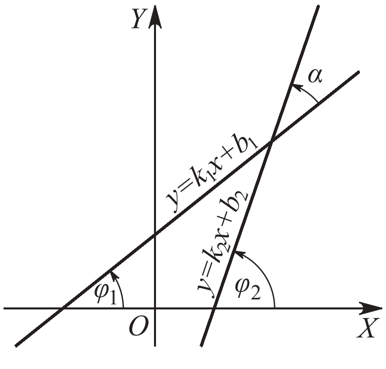

Figure M4.6. Angle between two straight lines.

Example 2. Given a triangle with vertices $A(-2, 0)$, $B(2, 4)$, and $C(4, 0)$, derive the equations of the side BC and the altitude AH.

Using (M4.2.1.5), one finds an equation for the side BC: $\frac{x-2}{4-2} = \frac{y-4}{0-4}$, or $y = -2x + 8$. It follows that the slope of this straight line is $k_{BC} = -2$. The above condition for two straight lines to be perpendicular gives $k_{AH} = -\frac{1}{k_{BC}} = \frac{1}{2}$. Using equation (M4.2.1.4), one obtains the equation for the altitude AH: $y - 0 = \frac{1}{2}(x + 2)$ or $y = \frac{1}{2}x + 1$.

2°. If two straight lines are defined by the general equations

$$\begin{aligned} A_1x + B_1y + C_1 &= 0,\\ A_2x + B_2y + C_2 &= 0, \end{aligned} \tag{M4.2.2.2}$$

the angle α between them can be calculated from

$$\tan\alpha = \frac{A_1B_2 - A_2B_1}{A_1A_2 + B_1B_2} \qquad (A_1A_2 + B_1B_2 \neq 0).$$

If $A_1B_2 - A_2B_1 = 0$ (or $A_1/A_2 = B_1/B_2$), the straight lines are *parallel*.
If $A_1A_2 + B_1B_2 = 0$, the straight lines are *perpendicular*.

► **Point of intersection of straight lines.** Suppose that two straight lines are defined by general equations in the form (M4.2.2.2). Each common solution of equations (M4.2.2.2) determines a common point of the two lines.

If the determinant of system (M4.2.2.2) is not zero, i.e.,

$$\begin{vmatrix} A_1 & B_1 \\ A_2 & B_2 \end{vmatrix} = A_1B_2 - A_2B_1 \neq 0,$$

then the system is consistent and has a unique solution; hence, these straight lines are distinct and nonparallel and meet at the point $A(x_0, y_0)$, where

$$x_0 = \frac{B_1C_2 - B_2C_1}{A_1B_2 - A_2B_1}, \quad y_0 = \frac{C_1A_2 - C_2A_1}{A_1B_2 - A_2B_1}.$$

► **Distance between parallel lines.** The distance between the parallel lines given by equations

$$A_1x + B_1y + C_1 = 0 \quad \text{and} \quad A_1x + B_1y + C_2 = 0$$

can be found using the formula

$$d = \frac{|C_1 - C_2|}{\sqrt{A_1^2 + B_1^2}}.$$

M4.3. Quadratic Curves

M4.3.1. Circle

► **Equations of a circle in the Cartesian coordinate system.** The *canonical equation of a circle* in a rectangular Cartesian coordinate system OXY has the form

$$x^2 + y^2 = a^2, \tag{M4.3.1.1}$$

where the point $O(0, 0)$ is the center of the circle and $a > 0$ is its radius (see Fig. M4.7*a*). The circle defined by equation (M4.3.1.1) is the locus of points equidistant (lying at the distance a) from its center.

The circle with radius a and center $A(x_0, y_0)$ is defined by the equation

$$(x - x_0)^2 + (y - y_0)^2 = a^2. \tag{M4.3.1.2}$$

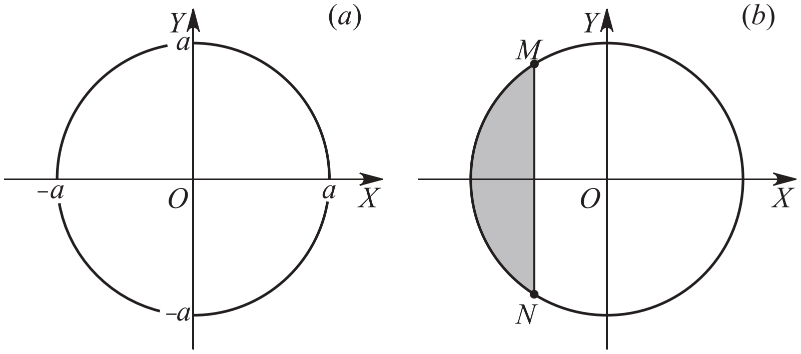

Figure M4.7. Circle.

The circle that passes through three noncollinear points $A_1(x_1,y_1)$, $A_2(x_2,y_2)$, and $A_3(x_3,y_3)$ can be described by the determinant equation

$$\begin{vmatrix} x^2+y^2 & x & y & 1 \\ x_1^2+y_1^2 & x_1 & y_1 & 1 \\ x_2^2+y_2^2 & x_2 & y_2 & 1 \\ x_3^2+y_3^2 & x_3 & y_3 & 1 \end{vmatrix} = 0.$$

The area of the *disk* bounded by a circle of radius a is given by the formula $S=\pi a^2$. The circumference of this circle is $L=2\pi a$. The area of the figure bounded by the circle and a chord with endpoints $M(x_0,y_0)$ and $N(x_0,-y_0)$, shaded in Fig. 4.7*b*, is expressed as

$$S=\frac{\pi a^2}{2}+x_0\sqrt{a^2-x_0^2}+a^2\arcsin\frac{x_0}{a}.$$

See also Subsection M3.1.3.

► **Other equations of a circle.** The equation of the circle (M4.3.1.1) can be represented in parametric form as

$$x=a\cos\theta,\quad y=a\sin\theta,$$

where the polar angle θ plays the role of the variable parameter.

In the polar coordinate system, the equation of the circle (M4.3.1.1) becomes

$$\rho=a.$$

Note that it does not contain the polar angle θ.

M4.3.2. Ellipse

► **Definition and the canonical equation of an ellipse.** An *ellipse* is the locus of points in the plane the sum of whose distances to two points, F_1 and F_2, is a constant quantity, denoted $2a$; see Fig. M4.8 *a*. Either of the points F_1 and F_2 is called a *focus* of the ellipse and the distance between them, $\rho(F_1,F_2)=2c$, is called the *focal distance*.

In the rectangular Cartesian coordinate system where the X-axis is the straight line passing through the foci, the origin O coincides with the midpoint of the segment F_1F_2, and the Y-axis passes through O and is perpendicular to the X-axis, as shown in Fig. M4.8 *a*, the equation of the ellipse has the simplest form

$$\frac{x^2}{a^2}+\frac{y^2}{b^2}=1. \qquad \text{(M4.3.2.1)}$$

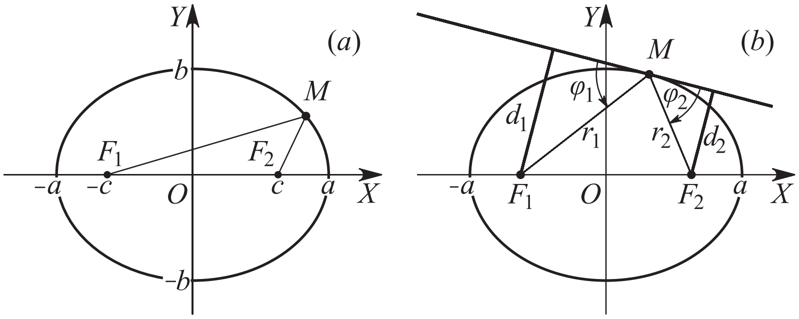

Figure M4.8. Ellipse (*a*). Tangent to an ellipse and the optical property of an ellipse (*b*).

Equation (M4.3.2.1) is called the *canonical equation of the ellipse*. Here, it is assumed that $a \ge b > 0$.

The positive numbers a and b are called, respectively, the *semimajor axis* and *semiminor axis* of the ellipse, with $b = \sqrt{a^2 - c^2}$. The number $c = \sqrt{a^2 - b^2}$ is called the *linear eccentricity* of the ellipse. The number $e = c/a = \sqrt{1 - b^2/a^2}$ is called the *eccentricity* or the *numerical eccentricity* of the ellipse, with $0 \le e < 1$. The number $p = b^2/a$ is called the *focal parameter* (or simply the *parameter*) of the ellipse.

The point $O(0,0)$ is called the *center* of the ellipse. The points of intersection of the ellipse with the axes of symmetry, $A_1(-a,0)$, $A_2(a,0)$ and $B_1(0,-b)$, $B_2(0,b)$, are called its *vertices*. The straight line passing through the foci of an ellipse is known as its major axis and is sometimes called its *focal axis*. Either of the straight lines $x = \pm a/e$ $(e \ne 0)$ is called a *directrix* of the ellipse. The focus $F_2(c,0)$ and the directrix $x = a/e$ are said to be *right*, and the focus $F_1(-c,0)$ and the directrix $x = -a/e$ are said to be *left*.

Remark. For $a = b$ $(c = 0)$, equation (M4.3.2.1) becomes $x^2 + y^2 = a^2$ and determines a circle.

The area of the figure bounded by the ellipse is given by the formula $S = \pi ab$. The length of the ellipse can be calculated approximately by the formula $L \approx \pi\bigl[1.5\,(a+b) - \sqrt{ab}\,\bigr]$.

► **Focal and focus-directrix properties of an ellipse.** The segments joining a point $M(x,y)$ of an ellipse with the foci $F_1(-c,0)$ and $F_2(c,0)$ are called the *left* and *right focal radii* of this point. We denote the lengths of the left and right focal radii by $r_1 = |F_1M|$ and $r_2 = |F_2M|$, respectively (see Fig. M4.8 *b*). By the definition of an ellipse,

$$r_1 + r_2 = 2a,$$

where r_1 and r_2 satisfy the relations

$$r_1 = \sqrt{(x+c)^2 + y^2} = a + ex, \qquad r_2 = \sqrt{(x-c)^2 + y^2} = a - ex.$$

The ellipse determined by equation (M4.3.2.1) on the plane is the locus of points for which the ratio of distances to a focus and the like directrix is equal to e:

$$r_1\left|x + \frac{a}{e}\right|^{-1} = e, \qquad r_2\left|x - \frac{a}{e}\right|^{-1} = e.$$

(A focus and a directrix are said to be *like* if both of them are right or left simultaneously.)

► **Equation of a tangent and the optical property of an ellipse.** The tangent to the ellipse (M4.3.2.1) at an arbitrary point $M_0(x_0, y_0)$ is given by the equation

$$\frac{x_0 x}{a^2} + \frac{y_0 y}{b^2} = 1.$$

The distances d_1 and d_2 from the foci $F_1(-c,0)$ and $F_2(c,0)$ to the tangent to the ellipse at the point $M_0(x_0,y_0)$ are expressed as

$$d_1 = \frac{1}{aN}|x_0e + a| = \frac{r_1}{aN}, \qquad N = \sqrt{\left(\frac{x_0}{a^2}\right)^2 + \left(\frac{y_0}{b^2}\right)^2},$$
$$d_2 = \frac{1}{aN}|x_0e - a| = \frac{r_2}{aN},$$

where $r_1 = r_1(M_0)$ and $r_2 = r_2(M_0)$ are the lengths of the focal radii of M_0 (see Fig. M4.8 *b*, where $M = M_0$).

The tangent at an arbitrary point $M_0(x_0,y_0)$ of an ellipse forms acute angles φ_1 and φ_2 with the focal radii of the point of tangency, and

$$\sin\varphi_1 = \frac{d_1}{r_1} = \frac{1}{aN}, \qquad \sin\varphi_2 = \frac{d_2}{r_2} = \frac{1}{aN}.$$

This fact, written as

$$\varphi_1 = \varphi_2,$$

is known as the *optical property of an ellipse*. It means that a light ray issued from one focus of the ellipse will reflect to the other focus (see Fig. M4.8 *b*, where $M = M_0$).

► **Equations of an ellipse in polar coordinates and parametric equations.** In polar coordinates (ρ,φ), with the pole coinciding with the right focus and the polar axis directed along the X-axis, the equation of an ellipse has the form

$$\rho = \frac{p}{1 + e\cos\varphi},$$

where $0 \le \varphi \le 2\pi$, $p = b^2/a$, and $e = \sqrt{1 - b^2/a^2}$. If the pole is taken at the left focus, this equation becomes

$$\rho = \frac{p}{1 - e\cos\varphi}.$$

The equation of an ellipse can also be represented in the parametric form

$$x = a\cos t, \quad y = b\sin t,$$

with the parameter t assuming any values from 0 to 2π.

M4.3.3. Hyperbola

► **Definition and the canonical equation of a hyperbola.** A *hyperbola* is the locus of points in the plane the absolute difference of whose distances to two points, F_1 and F_2, is a constant quantity, denoted $2a$; see Fig. M4.9 *a*. Either of the points F_1 and F_2 is called a *focus* of the hyperbola and the distance between them, $\rho(F_1,F_2) = 2c$, is called the *focal distance*.

In the rectangular Cartesian coordinate system where the X-axis is the straight line passing through the foci, the origin O coincides with the midpoint of the segment F_1F_2, and the Y-axis passes through O and is perpendicular to the X-axis, as shown in Fig. M4.8 *a*, the equation of the hyperbola has the simplest form

$$\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1, \qquad \text{(M4.3.3.1)}$$

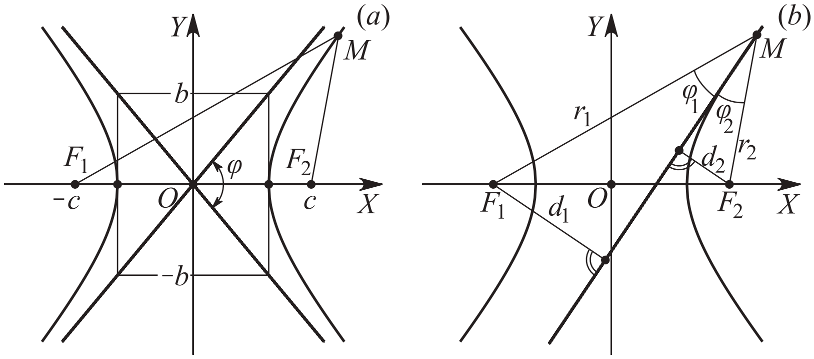

Figure M4.9. Hyperbola (*a*). The tangent to the hyperbola and optical property of a hyperbola (*b*).

and is called the *canonical equation of the hyperbola*.

The number a is called the *real semiaxis* of the hyperbola and the number b is called its *imaginary semiaxis*, with $b = \sqrt{c^2 - a^2}$. The number $c = \sqrt{a^2 + b^2}$ is known as the *linear eccentricity* of the hyperbola and the number $e = c/a = \sqrt{1 + b^2/a^2}$ is its *eccentricity*, $e > 1$. The number $p = b^2/a$ is called the *focal parameter* (or simply the *parameter*) of the hyperbola.

The point $O(0,0)$ is called the *center* of the hyperbola. The points $(-a,0)$ and $(a,0)$ at which the hyperbola crosses the X-axis are known as the *vertices* of the hyperbola. Either of the straight lines $x = \pm a/e$ is called a *directrix* of the hyperbola. The focus $F_2(c,0)$ and the directrix $x = a/e$ are said to be *right*, while the focus $F_1(-c,0)$ and the directrix $x = -a/e$ are said to be *left*.

A hyperbola consists of two parts, called its *branches*, lying in the domains $x \geq a$ and $x \leq -a$. It has two *asymptotes*, straight lines the hyperbola approaches at large distances from its center, which are given by

$$y = \frac{b}{a}x \quad \text{and} \quad y = -\frac{b}{a}x.$$

The branches of a hyperbola lie within two vertical angles formed by the asymptotes and are called its *left* and *right* branches. The angle φ between the asymptotes of a hyperbola is determined by the equation

$$\tan\frac{\varphi}{2} = \frac{b}{a}.$$

Remark. If $a = b$ ($e = \sqrt{2}$), then $\varphi = \frac{1}{2}\pi$. In this case, the hyperbola is said to be *equilateral* or *rectangular* and its asymptotes are mutually perpendicular. The equation of an equilateral hyperbola has the form $x^2 - y^2 = a^2$. If the asymptotes are taken to be the coordinate axes, then the equation of the hyperbola becomes $xy = a^2/2$; i.e., an equilateral hyperbola represents an inverse proportionality dependence.

► **Focal and focus-directrix properties of a hyperbola.** The segments joining a point $M(x,y)$ of the hyperbola with the foci $F_1(-c,0)$ and $F_2(c,0)$ are called the *left* and *right focal radii* of this point. We denote the lengths of the left and right focal radii by $r_1 = |F_1M|$ and $r_2 = |F_2M|$, respectively (see Fig. M4.9 *b*). By the definition of a hyperbola,

$$|r_1 - r_2| = 2a,$$

where r_1 and r_2 satisfy the relations

$$r_1 = \sqrt{(x+c)^2 + y^2} = \begin{cases} a + ex & \text{for } x > 0, \\ -a - ex & \text{for } x < 0, \end{cases}$$

$$r_2 = \sqrt{(x-c)^2 + y^2} = \begin{cases} -a + ex & \text{for } x > 0, \\ a - ex & \text{for } x < 0. \end{cases}$$

The hyperbola defined by equation (M4.3.3.1) on the plane is the locus of points for which the ratio of distances to a focus and the like directrix is equal to e:

$$r_1\left|x+\frac{a}{e}\right|^{-1}=e,\qquad r_2\left|x-\frac{a}{e}\right|^{-1}=e.$$

(A focus and a directrix are said to be *like* if both of them are right or left simultaneously.)

▶ **Equation of a tangent and the optical property of a hyperbola.** The tangent to the hyperbola (M4.3.3.1) at an arbitrary point $M_0(x_0,y_0)$ is given by the equation

$$\frac{x_0x}{a^2}-\frac{y_0y}{b^2}=1.$$

The distances d_1 and d_2 from the foci $F_1(-c,0)$ and $F_2(0,c)$ to the tangent to the hyperbola at the point $M_0(x_0,y_0)$ are expressed as

$$d_1=\frac{|x_0e+a|}{aN}=\frac{r_1}{aN},\qquad N=\sqrt{\left(\frac{x_0}{a^2}\right)^2+\left(\frac{y_0}{b^2}\right)^2},$$
$$d_2=\frac{|x_0e-a|}{aN}=\frac{r_2}{aN},$$

where r_1 and r_2 are the lengths of the focal radii of the point M_0 (see Fig. M4.9 b, where $M=M_0$).

The tangent at any point $M_0(x_0,y_0)$ of the hyperbola forms acute angles φ_1 and φ_2 with the focal radii of the point of tangency, and

$$\sin\varphi_1=\frac{d_1}{r_1}=\frac{1}{aN},\quad \sin\varphi_2=\frac{d_2}{r_2}=\frac{1}{aN}.$$

This fact, written as

$$\varphi_1=\varphi_2,$$

is known as the *optical property of a hyperbola*. It means that a light ray issued from a focus of the hyperbola will reflect so as to appear as though issued from the other focus (see Fig. M4.9 b, where $M=M_0$).

The tangent to a hyperbola at any point bisects the angles between the straight lines joining this point with the foci. The tangent to a hyperbola at either of its vertices intersects the asymptotes at two points such that the distance between them is equal to $2b$.

▶ **Equations of a hyperbola in polar coordinates and parametric equations.** In polar coordinates (ρ,φ), with the pole coinciding with the right focus and the polar axis directed along the X-axis, the equation of the hyperbola has the form

$$\rho=\frac{p}{1-e\cos\varphi},$$

where $0\le\varphi\le2\pi$, $p=b^2/a$, and $e=\sqrt{1+b^2/a^2}$. If the pole is taken at the left focus, the equation of the hyperbola becomes

$$\rho=\frac{p}{1+e\cos\varphi}.$$

A parametric representation for the right branch of a hyperbola is given by the equations

$$x=a\cosh t,\quad y=b\sinh t,$$

with the parameter t assuming any real values.

A parametric representation that covers both branches of a hyperbola is given by the equations

$$x=a\sec t,\quad y=b\tan t,$$

with $-\pi\le t\le\pi$ and $t\ne\pm\frac{1}{2}\pi$.

M4.3.4. Parabola

► **Definition and the canonical equation of a parabola.** A *parabola* is the locus of all points in the plane equidistant from a given point F and a given straight line l, with $F \notin l$; see Fig. M4.10 a. The point F is called the *focus* of the parabola and the straight line l is its *directrix*.

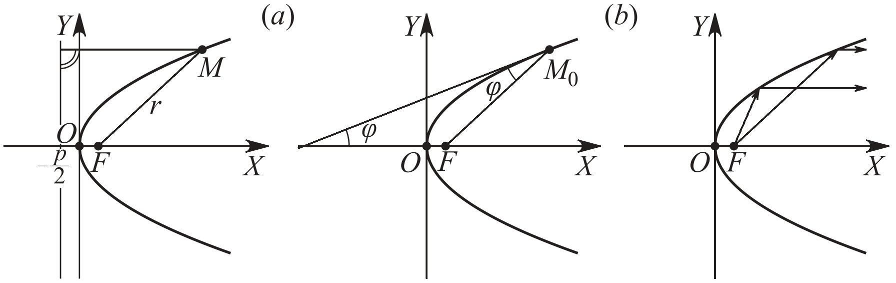

Figure M4.10. Parabola (a). Tangent to a parabola (b). Optical property of a parabola (c).

Let us draw a straight line through the focus F and perpendicularly to the directrix and denote the point at which this line crosses the directrix by C. Introduce the following Cartesian coordinate system: take the above line to be the X-axis (directed from C to F), the midpoint of the segment CF to be the origin O, and the perpendicular line through O to be the Y-axis. In this coordinate system, the parabola is determined by the equation

$$y^2 = 2px, \tag{M4.3.4.1}$$

where $p = |FC| > 0$. The number p is called *focal parameter* and equation (M4.3.4.1) is called the *canonical equation of the parabola*.

A parabola consists of an infinite branch symmetric about the X-axis. The point $O(0,0)$ is called the *vertex* of the parabola. The directrix of the parabola is given by the equation $x = -p/2$. The number $p/2$ is known as the *focal distance*. The segment joining a point $M(x,y)$ on the parabola with the focus $F(p/2,0)$ is called the *focal radius* of the point.

► **Focal properties of a parabola.** If r denotes the length of the focal radius FM, then by the definition of a parabola,

$$r = x + \frac{p}{2}.$$

As is apparent from Fig. M4.10a, the number r also satisfies the relation

$$r = \sqrt{\left(x - \frac{p}{2}\right)^2 + y^2}.$$

► **Equation of a tangent and the optical property of a parabola.** The tangent to the parabola (M4.3.4.1) at an arbitrary point $M_0(x_0, y_0)$ is given by the equation

$$yy_0 = p(x + x_0). \tag{M4.3.4.2}$$

The angle φ between the tangent to the parabola at a point $M_0(x_0, y_0)$ and the focal radius FM_0 is determined by

$$\cos\varphi = \frac{y_0}{\sqrt{y_0^2 + p^2}}.$$

The same relation holds for the angle between the tangent (M4.3.4.2) and the X-axis. This property of a parabola is called its *optical property*: a light ray issued from the focus reflects off the parabola in the direction parallel to the parabola axis (see Fig. M4.10 *c*).

► **Equation of a parabola in polar coordinates and parametric equations.** In polar coordinates (ρ, φ), with the pole at the focus of the parabola and the polar axis directed along the parabola axis, the equation of the parabola has the form

$$\rho = \frac{p}{1 - \cos\varphi},$$

where $0 < \varphi < 2\pi$.

Parametric equations of a parabola are

$$x = \tfrac{1}{2}pt^2, \quad y = pt,$$

with the parameter t assuming any real values.

M4.3.5. Transformation of Quadratic Curves to Canonical Form

► **General equation of a quadratic curve. Translation and rotation.** A set of points in the plane whose coordinates in the rectangular Cartesian coordinate system satisfy the general second-order algebraic equation

$$a_{11}x^2 + 2a_{12}xy + a_{22}y^2 + 2a_{13}x + 2a_{23}y + a_{33} = 0 \qquad \text{(M4.3.5.1)}$$

is called a (bivariate) *quadratic curve* (or just *quadratic*); it is also known as a *second-order curve*. If equation (M4.3.5.1) does not determine a real geometric object, this equation is said to determine an *imaginary quadratic curve*.

Equation (M4.3.5.1) may be simplified using the following transformations of the Cartesian coordinate system:

1. Translation:

$$x = \bar{x} + x_0, \qquad y = \bar{y} + y_0. \qquad \text{(M4.3.5.2)}$$

It means that the origin $O(0,0)$ is transferred to the point $\bar{O}(x_0, y_0)$ and the coordinate axes are moved parallel to the original ones; $\bar{x}$ and $\bar{y}$ denote the new coordinates.

2. Rotation:

$$x = \hat{x}\cos\varphi - \hat{y}\sin\varphi, \qquad y = \hat{x}\sin\varphi + \hat{y}\cos\varphi. \qquad \text{(M4.3.5.3)}$$

The coordinate axes are rotated about the origin, which does not move, by the angle φ counterclockwise; $\hat{x}$ and $\hat{y}$ denote the new coordinates.

► **Canonical equations of quadratic curves. The classification table.** With transformations (M4.3.5.2)–(M4.3.5.3), equation (M4.3.5.1) can be reduced to one of the *nine canonical forms* classified in Table M4.1. The first five curves, with $\delta \neq 0$, are *nondegenerate* (their canonical equations contain two quadratic terms proportional to x^2 and y^2). The last four curves, with $\delta = 0$, are *degenerate* (their canonical equations contain only one quadratic term, x^2 or y^2). Curves 3, 5, 7, 8, and 9, with $\Delta = 0$, split into straight lines; their equations can be represented as the product of two factors linear in the coordinates, each having the form $(\alpha_n x + \beta_n y + \gamma_n)$, on the left-hand side and zero on the right-hand side.

TABLE M4.1
Classification of quadratic curves.

No.	Curve name	Canonical equation	Conditions for invariants
1	Ellipse	$\dfrac{x^2}{a^2}+\dfrac{y^2}{b^2}=1$	$\delta>0,\ I\Delta<0$
2	Imaginary ellipse (no real points)	$\dfrac{x^2}{a^2}+\dfrac{y^2}{b^2}=-1$	$\delta>0,\ I\Delta>0$
3	Pair of imaginary straight lines intersecting at a real point	$\dfrac{x^2}{a^2}+\dfrac{y^2}{b^2}=0$	$\delta>0,\ \Delta=0$
4	Hyperbola	$\dfrac{x^2}{a^2}-\dfrac{y^2}{b^2}=1$	$\delta<0,\ \Delta\neq0$
5	Pair of intersecting straight lines (degenerate hyperbola)	$\dfrac{x^2}{a^2}-\dfrac{y^2}{b^2}=0$	$\delta<0,\ \Delta=0$
6	Parabola	$y^2=2px$	$\delta=0,\ \Delta\neq0$
7	Pair of parallel straight lines	$x^2-a^2=0$	$\delta=\Delta=0,\ \sigma<0$
8	Pair of imaginary parallel straight lines (no real points)	$x^2+a^2=0$	$\delta=\Delta=0,\ \sigma>0$
9	Pair of coinciding straight lines	$x^2=0$	$\delta=\Delta=\sigma=0$

► **Invariants of quadratic curves.** Quadratic curves can be studied using the three *invariants*

$$I=a_{11}+a_{22},\quad \delta=\begin{vmatrix}a_{11}&a_{12}\\a_{12}&a_{22}\end{vmatrix},\quad \Delta=\begin{vmatrix}a_{11}&a_{12}&a_{13}\\a_{12}&a_{22}&a_{23}\\a_{13}&a_{23}&a_{33}\end{vmatrix},\tag{M4.3.5.4}$$

whose values do not change under parallel translations and rotations of the coordinate axes, and the sign of the quantity

$$\sigma=\begin{vmatrix}a_{11}&a_{13}\\a_{13}&a_{33}\end{vmatrix}+\begin{vmatrix}a_{22}&a_{23}\\a_{23}&a_{33}\end{vmatrix}.\tag{M4.3.5.5}$$

The invariant Δ is called the *large discriminant* of equation (M4.3.5.1). The invariant δ is called the *small discriminant*.

The quadratic curves can be classified based on the values of the invariants, specified in the last column in Table M4.1.

► **Characteristic equation of quadratic curves.** The properties of quadratic curves can be studied using the *characteristic equation*

$$\begin{vmatrix}a_{11}-\lambda&a_{12}\\a_{12}&a_{22}-\lambda\end{vmatrix}=0\quad\text{or}\quad\lambda^2-I\lambda+\delta=0.\tag{M4.3.5.6}$$

The roots λ_1 and λ_2 of the characteristic equation (M4.3.5.6) are eigenvalues of a real symmetric matrix, $[a_{ij}]$, and hence are real.

The invariants I and δ are expressed in terms of the roots λ_1 and λ_2 as follows:

$$I=\lambda_1+\lambda_2,\quad \delta=\lambda_1\lambda_2.\tag{M4.3.5.7}$$

► **Nondegenerate case $\delta\neq0$. Reduction of quadratic curves to canonical form.** First, by applying the translation transformation (M4.3.5.2) with

$$x_0=-\frac{1}{\delta}\begin{vmatrix}a_{13}&a_{12}\\a_{23}&a_{22}\end{vmatrix},\quad y_0=-\frac{1}{\delta}\begin{vmatrix}a_{11}&a_{13}\\a_{12}&a_{23}\end{vmatrix},$$

one reduces equation (M4.3.5.1) to the form

$$a_{11}\bar{x}^2 + 2a_{12}\bar{x}\bar{y} + a_{22}\bar{y}^2 + \frac{\Delta}{\delta} = 0. \qquad \text{(M4.3.5.8)}$$

Then, with the rotation transformation (M4.3.5.3) where $\bar{x}$ and $\bar{y}$ are substituted for x and y and the angle φ determined by

$$\tan 2\varphi = \frac{2a_{12}}{a_{11} - a_{22}} \qquad \Bigl(\text{if } a_{11} = a_{22}, \text{ then } \varphi = \frac{\pi}{4}\Bigr),$$

equation (M4.3.5.8) is transformed into

$$\lambda_1 \hat{x}^2 + \lambda_2 \hat{y}^2 + \frac{\Delta}{\delta} = 0,$$

where λ_1 and λ_2 are the roots of the characteristic equation (M4.3.5.6).

Note the following formulas for an ellipse:

$$a^2 = -\frac{1}{\lambda_2}\frac{\Delta}{\delta} = -\frac{\Delta}{\lambda_1\lambda_2^2}, \quad b^2 = -\frac{1}{\lambda_1}\frac{\Delta}{\delta} = -\frac{\Delta}{\lambda_1^2\lambda_2} \qquad (\lambda_1 \ge \lambda_2),$$

where a and b are the semimajor and semiminor axes of the ellipse.

Similar formulas for a hyperbola have the form

$$a^2 = -\frac{1}{\lambda_1}\frac{\Delta}{\delta} = -\frac{\Delta}{\lambda_1^2\lambda_2}, \quad b^2 = \frac{1}{\lambda_1}\frac{\Delta}{\delta} = \frac{\Delta}{\lambda_1^2\lambda_2} \qquad (\lambda_1 \ge \lambda_2).$$

► **Degenerate case $\delta = 0$. Reduction of quadratic curves to canonical form.** If $\delta = 0$, equation (M4.3.5.1) can be rewritten as

$$(\alpha x + \beta y)^2 + 2a_{13}x + 2a_{23}y + a_{33} = 0. \qquad \text{(M4.3.5.9)}$$

If the coefficients a_{13} and a_{23} are respectively proportional to α and β, i.e., $a_{13} = k\alpha$ and $a_{23} = k\beta$, then equation (M4.3.5.9) becomes $(\alpha x + \beta y)^2 + 2k(\alpha x + \beta y) + a_{33} = 0$, and hence

$$\alpha x + \beta y = -k \pm \sqrt{k^2 - a_{33}},$$

which determines a pair of real (or imaginary) parallel straight lines.

If a_{13} and a_{23} are not proportional to α and β, then equation (M4.3.5.9) can be rewritten as

$$(\alpha x + \beta y + \gamma)^2 + 2k(\beta x - \alpha x + q) = 0. \qquad \text{(M4.3.5.10)}$$

The parameters k, γ, and q can be determined by comparing the coefficients in equations (M4.3.5.9) and (M4.3.5.10). If the line $\alpha x + \beta y + \gamma = 0$ is treated as the axis $\bar{O}\bar{X}$ and the line $\beta x - \alpha x + q = 0$ as the axis $\bar{O}\bar{Y}$ and the new coordinates are expressed as

$$\hat{x} = \frac{\beta x - \alpha x + q}{\pm\sqrt{\alpha^2 + \beta^2}}, \quad \hat{y} = \frac{\alpha x + \beta y + \gamma}{\pm\sqrt{\alpha^2 + \beta^2}},$$

then equation (M4.3.5.10) acquires the form

$$\hat{y}^2 = 2p\hat{x},$$

where $p = |k|/\sqrt{\alpha^2 + \beta^2}$. The axis $\bar{O}\bar{X}$ points to the half-plane where the sign of $\beta x - \alpha x + q$ is opposite to that of k.

The focal parameter p of a parabola is expressed in terms of the invariants I, δ, and Δ and the roots λ_1 and λ_2 ($\lambda_1 \ge \lambda_2$) of the characteristic equation (M4.3.5.6) as follows:

$$p = \frac{1}{I}\sqrt{-\frac{\Delta}{I}} = \frac{1}{\lambda_1}\sqrt{-\frac{\Delta}{\lambda_1}} > 0, \quad \lambda_2 = 0.$$

M4.4. Coordinates, Vectors, Curves, and Surfaces in Space

M4.4.1. Vectors and Their Properties

► **Notion of a vector.** A directed line segment connecting an initial point A and a terminal point B (see Fig. M4.11) is called a *vector* and denoted $\overrightarrow{AB}$. The nonnegative number equal to the length of the segment AB is called the *length* (or *magnitude*) of the *vector* $\overrightarrow{AB}$ and denoted $|\overrightarrow{AB}|$. The vector $\overrightarrow{BA}$ is said to be *opposite* to the vector $\overrightarrow{AB}$; it has the same magnitude but opposite direction. Vectors are usually denoted by a single lowercase letter, either with an arrow above (e.g., $\vec{a}$) or without (e.g., $\mathbf{a}$); the latter is the most common notation for vectors, in which case a boldface lowercase letter is used.

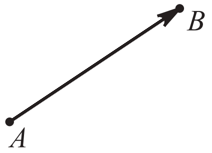

Figure M4.11. Vector $\overrightarrow{AB}$.

Two vectors are said to be *collinear* (*parallel*) if they lie on the same straight line or on parallel lines. Three vectors are said to be *coplanar* if they lie in the same plane or in parallel planes. A vector 0 whose initial and terminal points coincide is called the *zero vector* (or *null vector*); its length is zero ($|0| = 0$) and its direction is assumed to be arbitrary. A vector $\mathbf{e}$ of length one is called a *unit vector*.

Two vectors are called *equal* is they are collinear and have the same magnitude and direction. It follows that, for any vector $\mathbf{a}$ and any point A, there exists a unique vector $\overrightarrow{AB}$ with its start point at A that is equal to $\mathbf{a}$. For this reason, vectors in analytical geometry are defined up to their position, so that all vectors obtained from each other by parallel transport are considered to be the same.

► **Sum and difference of vectors.** The *sum* $\mathbf{a}+\mathbf{b}$ *of vectors* $\mathbf{a}$ *and* $\mathbf{b}$ is defined as the vector directed from the initial point of $\mathbf{a}$ to the terminal point of $\mathbf{b}$ where the start of $\mathbf{b}$ is placed at the tip of $\mathbf{a}$. This method of the addition of vectors is called the *triangle rule* (see Fig. M4.12 *a*). The sum $\mathbf{a}+\mathbf{b}$ can also be found using the *parallelogram rule* as shown in Fig. M4.12 *b*. The *difference* $\mathbf{a}-\mathbf{b}$ *of vectors* $\mathbf{a}$ *and* $\mathbf{b}$ is defined as the vector that must be added to $\mathbf{b}$ to get $\mathbf{a}$: $\mathbf{b}+(\mathbf{a}-\mathbf{b}) = \mathbf{a}$ (see Fig. M4.12 *c*).

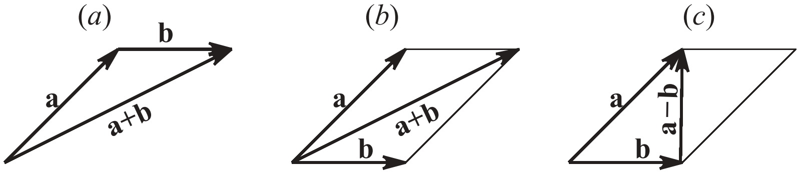

Figure M4.12. The sum of vectors: triangle rule (*a*) and parallelogram rule (*b*). The difference of vectors (*c*).

The *product* $\lambda\mathbf{a}$ *of a vector* $\mathbf{a}$ *by a number* λ is defined as the vector whose magnitude is equal to $|\lambda\mathbf{a}| = |\lambda||\mathbf{a}|$ and direction coincides with that of $\mathbf{a}$ if $\lambda > 0$ or is opposite to it if $\lambda < 0$.

Remark. If $\mathbf{a} = 0$ or $\lambda = 0$, then the resulting product is the zero vector. In this case, the direction of the product $\lambda\mathbf{a}$ is undetermined.

► **Main properties of operations with vectors.**

1. $\mathbf{a}+\mathbf{b}=\mathbf{b}+\mathbf{a}$ (commutativity).
2. $\mathbf{a}+(\mathbf{b}+\mathbf{c})=(\mathbf{a}+\mathbf{b})+\mathbf{c}$ (associativity of addition).
3. $\mathbf{a}+0=\mathbf{a}$ (existence of zero vector).
4. $\mathbf{a}+(-\mathbf{a})=0$ (existence of opposite vector).
5. $\lambda(\mathbf{a}+\mathbf{b})=\lambda\mathbf{a}+\lambda\mathbf{b}$ (distributivity with respect to addition of vectors).
6. $(\lambda+\mu)\mathbf{a}=\lambda\mathbf{a}+\mu\mathbf{a}$ (distributivity with respect to addition of constants).
7. $\lambda(\mu\mathbf{a})=(\lambda\mu)\mathbf{a}$ (associativity of product).
8. $1\mathbf{a}=\mathbf{a}$ (multiplication by unity).

M4.4.2. Coordinate Systems

► **Cartesian coordinate system. Some useful formulas.** A *rectangular Cartesian coordinate system* (also called just *rectangular coordinate system* or *Cartesian coordinate system*) is defined by three pairwise perpendicular directed straight lines OX, OY, and OZ (the *coordinate axes*) concurrent at a single point O (the *origin*).

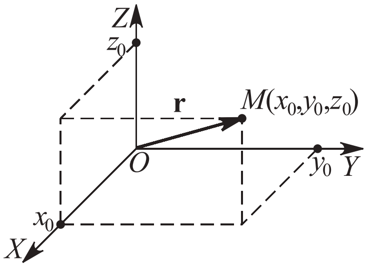

Figure M4.13. A point in a rectangular Cartesian coordinate system.

For an arbitrary point M in space, let us draw through it three planes parallel to the planes OYZ, OXZ, and OXY. These planes will intersect the coordinate axes OX, OY, and OZ at three points. Denote by x_0, y_0, and z_0 the distances from these points to the origin O (see Fig. M4.13). The numbers x_0, y_0, and z_0 are, respectively, called the x-coordinate (or *abscissa*), the y-coordinate (or *ordinate*), and the z-coordinate of the point M. One usually uses the notation $M(x_0,y_0,z_0)$ to specify that the point M has the coordinates (x_0,y_0,z_0).

Planes parallel to the coordinate planes are coordinate surfaces on which one of the coordinates is constant. Straight lines parallel to the coordinate axes are coordinate lines along which only one coordinate varies and the other two remain constant. Coordinate surfaces meet at coordinate lines.

Each point M in three-dimensional space uniquely defines a vector $\overrightarrow{OM}$, which is called the *position vector* of the point M. The coordinates of the position vector coincide with those of M and one usually writes $\mathbf{r}=\overrightarrow{OM}=(x_0,y_0,z_0)$.

The distance between two points, $M_1(x_1,y_1,z_1)$ and $M_2(x_2,y_2,z_2)$, is given by the formula

$$d=\sqrt{(x_2-x_1)^2+(y_2-y_1)^2+(z_2-z_1)^2}=|\mathbf{r}_2-\mathbf{r}_1|, \qquad \text{(M4.4.2.1)}$$

where $\mathbf{r}_2=\overrightarrow{OM}_2$ and $\mathbf{r}_1=\overrightarrow{OM}_1$ are the position vectors of the points M_1 and M_2, respectively (see Fig. M4.14).

Any triple of numbers (x,y,z) can be identified with a point P and a position vector $\overrightarrow{OP}$, whose coordinates are these numbers. An arbitrary vector (x,y,z) can be represented as

$$(x,y,z)=x\mathbf{i}+y\mathbf{j}+z\mathbf{k},$$

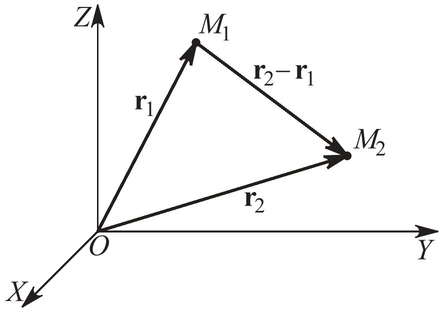

Figure M4.14. Distance between points.

where $\mathbf{i} = (1,0,0)$, $\mathbf{j} = (0,1,0)$, and $\mathbf{k} = (0,0,1)$ are the unit vectors with the same directions as the coordinate axes OX, OY, and OZ (*basis vectors*).

Two vectors $\mathbf{r}_1 = (x_1, y_1, z_1)$ and $\mathbf{r}_2 = (x_2, y_2, z_2)$ are equal to each other if and only if the relations

$$x_1 = x_2, \quad y_1 = y_2, \quad z_1 = z_2$$

hold simultaneously. The coordinates of the sum or difference of vectors and the product of a vector by a scalar are calculated as

$$(x_1, y_1, z_1) \pm (x_2, y_2, z_2) = (x_1 \pm x_2, y_1 \pm y_2, z_1 \pm z_2),$$
$$\alpha\,(x, y, z) = (\alpha x, \alpha y, \alpha z).$$

If a point M divides a directed segment $\overrightarrow{M_1M_2}$ in a ratio λ, then the coordinates of this point are given by

$$x = \frac{x_1 + \lambda x_2}{1+\lambda}, \quad y = \frac{y_1 + \lambda y_2}{1+\lambda}, \quad z = \frac{z_1 + \lambda z_2}{1+\lambda} \qquad \text{or} \qquad \mathbf{r} = \frac{\mathbf{r}_1 + \lambda \mathbf{r}_2}{1+\lambda}, \qquad \text{(M4.4.2.2)}$$

where $\lambda = |\overrightarrow{M_1M}|/|\overrightarrow{MM_2}|$. The special case where M is the midpoint of $\overrightarrow{M_1M_2}$ corresponds to $\lambda = 1$.

The angles α, β, and γ between $\overrightarrow{M_1M_2}$ and the coordinate axes OX, OY, and OZ are determined by

$$\cos\alpha = \frac{x_2 - x_1}{|\mathbf{r}_2 - \mathbf{r}_1|}, \quad \cos\beta = \frac{y_2 - y_1}{|\mathbf{r}_2 - \mathbf{r}_1|}, \quad \cos\gamma = \frac{z_2 - z_1}{|\mathbf{r}_2 - \mathbf{r}_1|},$$

with

$$\cos^2\alpha + \cos^2\beta + \cos^2\gamma = 1.$$

The numbers $\cos\alpha$, $\cos\beta$, and $\cos\gamma$ are called the *direction cosines* of the vector $\overrightarrow{M_1M_2}$.

The angle φ between two vectors $\overrightarrow{M_1M_2}$ and $\overrightarrow{M_3M_4}$ defined by the points $M_1(x_1, y_1, z_1)$, $M_2(x_2, y_2, z_2)$, $M_3(x_3, y_3, z_3)$, and $M_4(x_4, y_4, z_4)$ can be found from

$$\cos\varphi = \frac{(x_2 - x_1)(x_4 - x_3) + (y_2 - y_1)(y_4 - y_3) + (z_2 - z_1)(z_4 - z_3)}{|\mathbf{r}_2 - \mathbf{r}_1|\,|\mathbf{r}_4 - \mathbf{r}_3|}.$$

The area of the triangle with vertices M_1, M_2, and M_3 is given by the formula

$$S = \frac{1}{4}\sqrt{\begin{vmatrix} y_1 & z_1 & 1 \\ y_2 & z_2 & 1 \\ y_3 & z_3 & 1 \end{vmatrix}^2 + \begin{vmatrix} z_1 & x_1 & 1 \\ z_2 & x_2 & 1 \\ z_3 & x_3 & 1 \end{vmatrix}^2 + \begin{vmatrix} x_1 & y_1 & 1 \\ x_2 & y_2 & 1 \\ x_3 & y_3 & 1 \end{vmatrix}^2}.$$

The volume of the pyramid with vertices M_1, M_2, M_3, and M_4 is equal to

$$V = \frac{1}{6}|D|, \qquad D = \begin{vmatrix} x_2 - x_1 & y_2 - y_1 & z_2 - z_1 \\ x_3 - x_1 & y_3 - y_1 & z_3 - z_1 \\ x_4 - x_1 & y_4 - y_1 & z_4 - z_1 \end{vmatrix} = \begin{vmatrix} 1 & x_1 & y_1 & z_1 \\ 1 & x_2 & y_2 & z_2 \\ 1 & x_3 & y_3 & z_3 \\ 1 & x_4 & y_4 & z_4 \end{vmatrix},$$

and the volume of the parallelepiped spanned by vectors $\overrightarrow{M_1M_2}$, $\overrightarrow{M_1M_3}$, and $\overrightarrow{M_1M_4}$ is equal to

$$V = |D|.$$

► **Cylindrical coordinates.** *Cylindrical coordinates* are a generalization of polar coordinates (see Subsection M4.1.1) that adds a third dimension. If a point M is specified by its cylindrical coordinates, they are the polar coordinates ρ and φ of the projection of M onto a base plane (usually OXY) and the distance (usually z) of M from this base plane (see Fig. M4.15 *a*). It is usually assumed that $0 \le \varphi \le 2\pi$ (or $-\pi \le \varphi \le \pi$). For cylindrical coordinates, the coordinate surfaces are planes $z = \text{const}$ perpendicular to the axis OZ, half-planes $\varphi = \text{const}$ bounded by the axis OZ, and cylindrical surfaces $\rho = \text{const}$ with axis OZ.

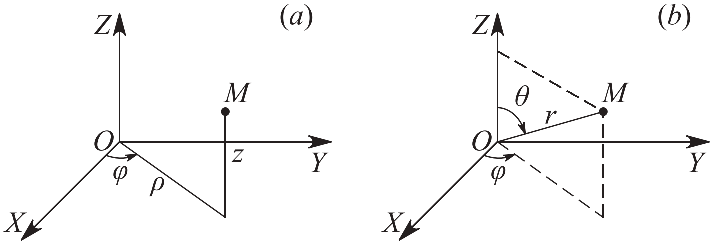

Figure M4.15. Point in cylindrical (*a*) and spherical (*b*) coordinates.

Let M be an arbitrary point in space with its Cartesian coordinates (x, y, z) and cylindrical coordinates (ρ, φ, z). The conversion formulas from Cartesian to cylindrical and from cylindrical to Cartesian coordinates are as follows:

$$\begin{aligned} x &= \rho\cos\varphi, & \rho &= \sqrt{x^2 + y^2}, \\ y &= \rho\sin\varphi, & \tan\varphi &= y/x, \\ z &= z, & z &= z, \end{aligned}$$

where the polar angle φ is taken with regard to the quadrant in which the projection of the point M onto the base plane lies.

► **Spherical coordinates.** The *spherical coordinates* of a point M are defined as the length $r = |\overrightarrow{OM}|$ of its position vector, the *azimuthal angle* φ from the positive direction of the axis OX to the projection of M onto the plane OXY, and the *zenithal angle* θ from the positive direction of the axis OZ to M (see Fig. M4.15 *b*). It is usually assumed that $0 \le \varphi \le 2\pi$ and $0 \le \theta \le \pi$ (or $-\pi \le \varphi \le \pi$ and $0 \le \theta \le \pi$). For spherical coordinates, the coordinate surfaces are spheres $r = \text{const}$ centered at the origin, half-planes $\varphi = \text{const}$ bounded by the axis OZ, and cones $\theta = \text{const}$ with vertex O and axis OZ.

The conversion formulas from the Cartesian coordinates (x, y, z) to the spherical coordinates (r, φ, θ) and back are as follows:

$$\begin{aligned} x &= r\sin\theta\cos\varphi, & r &= \sqrt{x^2 + y^2 + z^2}, \\ y &= r\sin\theta\sin\varphi, & \tan\varphi &= y/x, \\ z &= r\cos\theta, & \tan\theta &= \sqrt{x^2 + y^2}/z, \end{aligned}$$

where the angle φ is determined from the same considerations as in the case of cylindrical coordinates.

M4.4.3. Scalar, Cross, and Scalar Triple Products of Vectors

► **Scalar product of two vectors.** The *scalar product* (also known as the *dot product*) of two vectors **a** and **b**, is defined as the product of their magnitudes by the cosine of the angle between the vectors (see Fig. M4.16),

$$\mathbf{a}\cdot\mathbf{b} = |\mathbf{a}||\mathbf{b}|\cos\varphi.$$

It follows that $\mathbf{a}\cdot\mathbf{b} > 0$ if the angle between **a** and **b** is acute, $\mathbf{a}\cdot\mathbf{b} < 0$ if it is obtuse, and $\mathbf{a}\cdot\mathbf{b} = 0$ if it is right.

Remark. The scalar product of a vector **a** by a vector **b** is also denoted by $(\mathbf{a}\cdot\mathbf{b})$, $(\mathbf{a},\mathbf{b})$, and $\mathbf{ab}$.

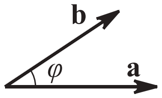

Figure M4.16. Scalar product of two vectors.

Properties of the scalar product:

1. $\mathbf{a}\cdot\mathbf{b} = \mathbf{b}\cdot\mathbf{a}$ (commutativity).
2. $\mathbf{a}\cdot(\mathbf{b}+\mathbf{c}) = \mathbf{a}\cdot\mathbf{b}+\mathbf{a}\cdot\mathbf{c}$ (distributivity with respect to addition of vectors). This property holds for any number of summands.
3. If **a** and **b** are collinear, then $\mathbf{a}\cdot\mathbf{b} = \pm|\mathbf{a}||\mathbf{b}|$. (The plus sign is taken if **a** and **b** have the same direction, and the minus sign is taken if they have opposite directions.)
4. $(\lambda\mathbf{a})\cdot\mathbf{b} = \lambda(\mathbf{a}\cdot\mathbf{b})$ (associativity with respect to a scalar factor).
5. $\mathbf{a}\cdot\mathbf{a} = |\mathbf{a}|^2$. The scalar product $\mathbf{a}\cdot\mathbf{a}$ is denoted by $\mathbf{a}^2$ (the *scalar square* of the vector **a**).
6. The magnitude of a vector is expressed via the scalar product as

$$|\mathbf{a}| = \sqrt{\mathbf{a}\cdot\mathbf{a}} = \sqrt{\mathbf{a}^2}.$$

7. Two nonzero vectors **a** and **b** are perpendicular if and only if $\mathbf{a}\cdot\mathbf{b} = 0$.
8. The scalar products of the basis vectors are

$$\mathbf{i}\cdot\mathbf{j} = \mathbf{i}\cdot\mathbf{k} = \mathbf{j}\cdot\mathbf{k} = 0, \quad \mathbf{i}\cdot\mathbf{i} = \mathbf{j}\cdot\mathbf{j} = \mathbf{k}\cdot\mathbf{k} = 1.$$

9. If vectors are given by their coordinates, $\mathbf{a} = (a_x, a_y, a_z)$ and $\mathbf{b} = (b_x, b_y, b_z)$, then

$$\mathbf{a}\cdot\mathbf{b} = (a_x\mathbf{i} + a_y\mathbf{j} + a_z\mathbf{k})(b_x\mathbf{i} + b_y\mathbf{j} + b_z\mathbf{k}) = a_xb_x + a_yb_y + a_zb_z.$$

10. The *Cauchy–Schwarz inequality*

$$|\mathbf{a}\cdot\mathbf{b}| \le |\mathbf{a}||\mathbf{b}|.$$

11. The *Minkowski inequality*

$$|\mathbf{a}+\mathbf{b}| \le |\mathbf{a}| + |\mathbf{b}|.$$

12. The *angle φ between vectors* **a** and **b** is determined by the formula

$$\cos\varphi = \frac{\mathbf{a}\cdot\mathbf{b}}{|\mathbf{a}||\mathbf{b}|} = \frac{a_xb_x + a_yb_y + a_zb_z}{\sqrt{a_x^2 + a_y^2 + a_z^2}\sqrt{b_x^2 + b_y^2 + b_z^2}}.$$

► **Cross product of two vectors.** The *cross product* of a vector **a** by a vector **b** is defined as the vector **c** denoted by $\mathbf{a}\times\mathbf{b}$ (see Fig. M4.17), satisfying the following three conditions:

1. Its absolute value (magnitude) is equal to the area of the parallelogram spanned by the vectors **a** and **b**; i.e.,
$$|\mathbf{c}| = |\mathbf{a}\times\mathbf{b}| = |\mathbf{a}||\mathbf{b}|\sin\varphi.$$
2. It is perpendicular to the plane of the parallelogram; i.e., $\mathbf{c}\perp\mathbf{a}$ and $\mathbf{c}\perp\mathbf{b}$.
3. The vectors **a**, **b**, and **c** form a *right-handed trihedral*; i.e., the vector **c** points to the side from which the sense of the shortest rotation from **a** to **b** is counterclockwise.

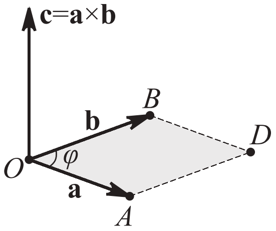

Figure M4.17. Cross product of two vectors.

Remark. The cross product of a vector **a** by a vector **b** is also denoted by $\mathbf{c} = [\mathbf{a},\mathbf{b}]$.

Properties of cross product:

1. $\mathbf{a}\times\mathbf{b} = -\mathbf{b}\times\mathbf{a}$ (anticommutativity).
2. $\mathbf{a}\times(\mathbf{b}+\mathbf{c}) = \mathbf{a}\times\mathbf{b}+\mathbf{a}\times\mathbf{c}$ (distributivity with respect to the addition of vectors). This property holds for any number of summands.
3. Vectors **a** and **b** are collinear if and only if $\mathbf{a}\times\mathbf{b} = 0$. In particular, $\mathbf{a}\times\mathbf{a} = 0$.
4. $(\lambda\mathbf{a})\times\mathbf{b} = \mathbf{a}\times(\lambda\mathbf{b}) = \lambda(\mathbf{a}\times\mathbf{b})$ (associativity with respect to a scalar factor).
5. The cross products of basis vectors are
$$\mathbf{i}\times\mathbf{i} = \mathbf{j}\times\mathbf{j} = \mathbf{k}\times\mathbf{k} = 0, \quad \mathbf{i}\times\mathbf{j} = \mathbf{k}, \quad \mathbf{j}\times\mathbf{k} = \mathbf{i}, \quad \mathbf{k}\times\mathbf{i} = \mathbf{j}.$$
6. If the vectors are given by their coordinates $\mathbf{a} = (a_x, a_y, a_z)$ and $\mathbf{b} = (b_x, b_y, b_z)$, then
$$\mathbf{a}\times\mathbf{b} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ a_x & a_y & a_z \\ b_x & b_y & b_z \end{vmatrix} = (a_y b_z - a_z b_y)\mathbf{i} + (a_z b_x - a_x b_z)\mathbf{j} + (a_x b_y - a_y b_x)\mathbf{k}.$$
7. The area of the parallelogram spanned by vectors **a** and **b** is equal to
$$S = |\mathbf{a}\times\mathbf{b}| = \sqrt{\begin{vmatrix} a_y & a_z \\ b_y & b_z \end{vmatrix}^2 + \begin{vmatrix} a_x & a_z \\ b_x & b_z \end{vmatrix}^2 + \begin{vmatrix} a_x & a_y \\ b_x & b_y \end{vmatrix}^2}.$$
8. The area of the triangle spanned by vectors **a** and **b** is equal to
$$S = \frac{1}{2}|\mathbf{a}\times\mathbf{b}| = \frac{1}{2}\sqrt{\begin{vmatrix} a_y & a_z \\ b_y & b_z \end{vmatrix}^2 + \begin{vmatrix} a_x & a_z \\ b_x & b_z \end{vmatrix}^2 + \begin{vmatrix} a_x & a_y \\ b_x & b_y \end{vmatrix}^2}.$$

► **Conditions for vectors to be parallel or perpendicular.**
A vector **a** is collinear to a vector **b** if
$$\mathbf{b} = \lambda\mathbf{a} \quad\text{or}\quad \mathbf{a}\times\mathbf{b} = 0.$$

A vector **a** is perpendicular to a vector **b** if

$$\mathbf{a}\cdot\mathbf{b} = 0.$$

Remark. In general, the condition $\mathbf{a}\cdot\mathbf{b} = 0$ implies that the vectors **a** and **b** are perpendicular or one of them is the zero vector. The zero vector can be viewed to be perpendicular to any other vector.

► **Scalar triple product of three vectors.** The *scalar triple product* of vectors **a**, **b**, and **c** is defined as the scalar product of **a** by the cross product of **b** and **c**:

$$[\mathbf{abc}] = \mathbf{a}\cdot(\mathbf{b}\times\mathbf{c}).$$

Remark. The scalar triple product of three vectors **a**, **b**, and **c** is also denoted by **abc**.

Properties of scalar triple product:

1. $[\mathbf{abc}] = [\mathbf{bca}] = [\mathbf{cab}] = -[\mathbf{bac}] = -[\mathbf{cba}] = -[\mathbf{acb}]$.
2. $[\mathbf{aab}] = [\mathbf{bab}] = 0$ or $\mathbf{a}\cdot(\mathbf{a}\times\mathbf{b}) = \mathbf{b}\cdot(\mathbf{a}\times\mathbf{b}) = 0$.
3. $[(\mathbf{a}+\mathbf{b})\mathbf{cd}] = [\mathbf{acd}] + [\mathbf{bcd}]$ (distributivity with respect to addition of vectors). This property holds for any number of summands.
4. $[\lambda\mathbf{abc}] = \lambda[\mathbf{abc}]$ (associativity with respect to a scalar factor).
5. If the vectors are given by their coordinates $\mathbf{a} = (a_x, a_y, a_z)$, $\mathbf{b} = (b_x, b_y, b_z)$, and $\mathbf{c} = (c_x, c_y, c_z)$, then
$$[\mathbf{abc}] = \begin{vmatrix} a_x & a_y & a_z \\ b_x & b_y & b_z \\ c_x & c_y & c_z \end{vmatrix}.$$
6. The scalar triple product [**abc**] is equal to the volume V of the parallelepiped spanned by the vectors **a**, **b**, and **c** taken with the sign + if the vectors **a**, **b**, and **c** form a right-handed trihedral and the sign – if the vectors form a left-handed trihedral,
$$[\mathbf{abc}] = \pm V.$$
7. Three nonzero vectors **a**, **b**, and **c** are coplanar if and only if $[\mathbf{abc}] = 0$. In this case, the vectors **a**, **b**, and **c** are linearly dependent; they satisfy a relation of the form $\alpha\mathbf{a} + \beta\mathbf{b} + \gamma\mathbf{c} = 0$.

M4.5. Line and Plane in Space

M4.5.1. Plane in Space

► **General equation of a plane.** In a Cartesian coordinate system, a plane is given by a first-order algebraic equation.

The *general* (*complete*) *equation of a plane* has the form

$$Ax + By + Cz + D = 0, \tag{M4.5.1.1}$$

where $A^2 + B^2 + C^2 \neq 0$.

1. For $D = 0$, the equation defines a plane passing through the origin.
2. For $A = 0$ (respectively, $B = 0$ or $C = 0$), the equation defines a plane parallel to the axis OX (respectively, OY or OZ).
3. For $A = D = 0$ (respectively, $B = D = 0$ or $C = D = 0$), the equation defines a plane passing through the axis OX (respectively, OY or OZ).
4. For $A = B = 0$ (respectively, $A = C = 0$ or $B = C = 0$), the equation defines a plane parallel to the plane OXY (respectively, OXZ or OYZ).

► **Intercept equation of a plane.** A plane $Ax+By+Cz+D=0$ that is not parallel to the axis OX (i.e., $A\neq 0$) meets this axis at a (signed) distance $a=-D/A$ from the origin (see Fig. M4.18). The number a is called the x-intercept of the plane. Similarly, one defines the y-intercepts $b=-D/B$ (for $B\neq 0$) and the z-intercept $c=-D/C$ (for $C\neq 0$). Then such a plane can be defined by the equation

$$\frac{x}{a}+\frac{y}{b}+\frac{z}{c}=1,$$

which is called the *intercept equation of the plane*.

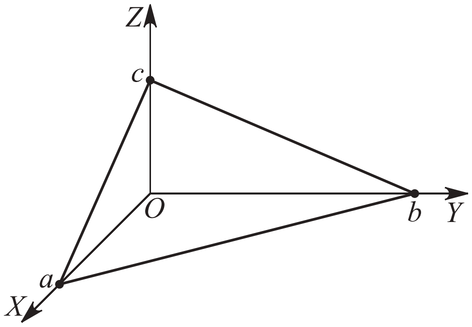

Figure M4.18. A plane with intercept equation.

Remark. A plane parallel to the axis OX but nonparallel to the other two axes is defined by the equation $y/b+z/c=1$, where b and c are the y- and z-intercepts of the plane. A plane simultaneously parallel to the axes OX and OY can be represented in the form $z/c=1$.

► **Equation of the plane passing through a point M_0 and perpendicular to a vector N.** The equation of the plane passing through a point $M_0(x_0,y_0,z_0)$ and perpendicular to a vector $\mathbf{N}=(A,B,C)$ has the form

$$A(x-x_0)+B(y-y_0)+C(z-z_0)=0, \qquad \text{or} \qquad (\mathbf{r}-\mathbf{r}_0)\cdot\mathbf{N}=0, \tag{M4.5.1.2}$$

where $\mathbf{r}$ and $\mathbf{r}_0$ are the position vectors of the points $M(x,y,z)$ and $M_0(x_0,y_0,z_0)$, respectively (see Fig. M4.19). The vector $\mathbf{N}$ is called a *normal vector*. Its direction cosines are

$$\cos\alpha=\frac{A}{\sqrt{A^2+B^2+C^2}},\quad \cos\beta=\frac{B}{\sqrt{A^2+B^2+C^2}},\quad \cos\gamma=\frac{C}{\sqrt{A^2+B^2+C^2}}.$$

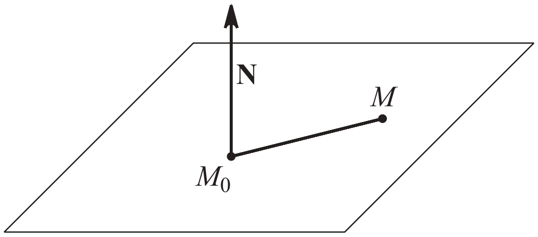

Figure M4.19. Plane passing through a point M_0 and perpendicular to a vector $\mathbf{N}$.

► **Equation of the plane passing through a point and parallel to another plane.** The plane that passes through a point $M_0(x_0, y_0, z_0)$ and is parallel to a plane $Ax+By+Cz+D=0$ is given by equation (M4.5.1.2).

► **Equation of the plane passing through three points.** The plane passing through three points $M_1(x_1, y_1, z_1)$, $M_2(x_2, y_2, z_2)$, and $M_3(x_3, y_3, z_3)$ (see Fig. M4.20) is described by the equation

$$\begin{vmatrix} x-x_1 & y-y_1 & z-z_1 \\ x_2-x_1 & y_2-y_1 & z_2-z_1 \\ x_3-x_1 & y_3-y_1 & z_3-z_1 \end{vmatrix} = 0, \qquad \text{or} \qquad \big[(\mathbf{r}-\mathbf{r}_1)(\mathbf{r}_2-\mathbf{r}_1)(\mathbf{r}_3-\mathbf{r}_1)\big] = 0, \quad \text{(M4.5.1.3)}$$

where $\mathbf{r}$, $\mathbf{r}_1$, $\mathbf{r}_2$, and $\mathbf{r}_3$ are the position vectors of the points $M(x, y, z)$, $M_1(x_1, y_1, z_1)$, $M_2(x_2, y_2, z_2)$, and $M_3(x_3, y_3, z_3)$, respectively.

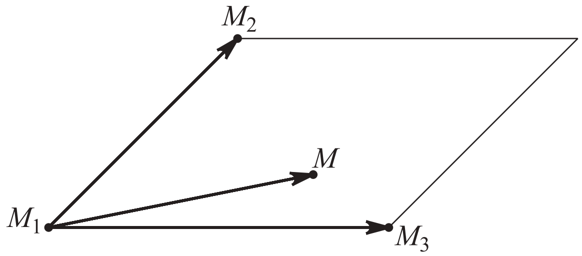

Figure M4.20. Plane passing through three points.

Remark 1. Equation (M4.5.1.3) means that the vectors $\overrightarrow{M_1M}$, $\overrightarrow{M_1M_2}$, and $\overrightarrow{M_1M_3}$ are coplanar.

Remark 2. If the three points $M_1(x_1, y_1, z_1)$, $M_2(x_2, y_2, z_2)$, and $M_3(x_3, y_3, z_3)$ are collinear, then equation (M4.5.1.3) is satisfied identically.

Example 1. Let us construct an equation of the plane passing through the three points $M_1(1, 1, 1)$, $M_2(2, 2, 1)$, and $M_3(1, 2, 2)$.

Obviously, the points M_1, M_2, and M_3 are not collinear, since the vectors $\overrightarrow{M_1M_2} = (1, 1, 0)$ and $\overrightarrow{M_1M_3} = (0, 1, 1)$ are not collinear. According to (M4.5.1.3), we have

$$\begin{vmatrix} x-1 & y-1 & z-1 \\ 1 & 1 & 0 \\ 0 & 1 & 1 \end{vmatrix} = 0,$$

whence the desired equation is $x - y + z - 1 = 0$.

► **Equation of the plane passing through two points and parallel to a straight line.** The plane passing through two points $M_1(x_1, y_1, z_1)$ and $M_2(x_2, y_2, z_2)$ and parallel to a straight line with direction vector $\mathbf{R} = (l, m, n)$ (see Fig. M4.21) is given by the equation

$$\begin{vmatrix} x-x_1 & y-y_1 & z-z_1 \\ x_2-x_1 & y_2-y_1 & z_2-z_1 \\ l & m & n \end{vmatrix} = 0, \qquad \text{or} \qquad \big[(\mathbf{r}-\mathbf{r}_1)(\mathbf{r}_2-\mathbf{r}_1)\mathbf{R}\big] = 0, \qquad \text{(M4.5.1.4)}$$

where $\mathbf{r}$, $\mathbf{r}_1$, and $\mathbf{r}_2$ are the position vectors of the points $M(x, y, z)$, $M_1(x_1, y_1, z_1)$, and $M_2(x_2, y_2, z_2)$, respectively.

Remark. If the vectors $\overrightarrow{M_1M_2}$ and $\mathbf{R}$ are collinear, then equations (M4.5.1.4) become identities.

Example 2. Find an equation of the plane passing through the points $M_1(0, 1, 0)$ and $M_2(1, 1, 1)$ and parallel to the straight line with direction vector $\mathbf{R} = (0, 1, 1)$.

According to (M4.5.1.4), we have

$$\begin{vmatrix} x-0 & y-1 & z-0 \\ 1-0 & 1-1 & 1-0 \\ 0 & 1 & 1 \end{vmatrix} = 0,$$

whence the desired equation is $-x - y + z + 1 = 0$.

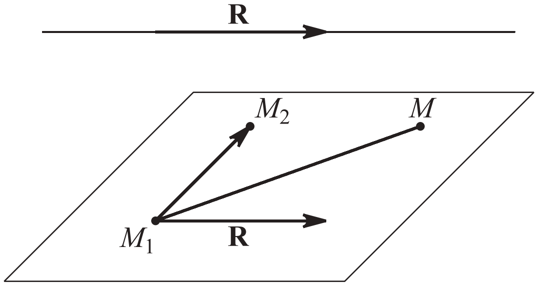

Figure M4.21. Plane passing through two points and parallel to a line.

► **Equation of the plane passing through a point and parallel to two straight lines.** The plane passing through a point $M_0(x_0, y_0, z_0)$ and parallel to two straight lines with direction vectors $\mathbf{R}_1 = (l_1, m_1, n_1)$ and $\mathbf{R}_2 = (l_2, m_2, n_2)$ is given by the equation

$$\begin{vmatrix} x-x_0 & y-y_0 & z-z_0 \\ l_1 & m_1 & n_1 \\ l_2 & m_2 & n_2 \end{vmatrix} = 0, \qquad \text{or} \qquad \bigl[(\mathbf{r}-\mathbf{r}_0)\mathbf{R}_1\mathbf{R}_2\bigr] = 0,$$

where $\mathbf{r}$ and $\mathbf{r}_0$ are the position vectors of the points $M(x, y, z)$ and $M_0(x_0, y_0, z_0)$, respectively.

The equation of the plane passing through a point $M_0(x_0, y_0, z_0)$ and parallel to two noncollinear vectors $\mathbf{R}_1 = (l_1, m_1, n_1)$ and $\mathbf{R}_2 = (l_2, m_2, n_2)$ can be represented in the form (M4.5.1.2) with A, B, and C being the coordinates of the vector $\mathbf{R} = \mathbf{R}_1 \times \mathbf{R}_2$.

Example 3. Find an equation of the plane P that passes through the point $M_0(2, -1, 1)$ and is perpendicular to the planes P_1 and P_2 defined by $3x + 2y - z + 4 = 0$ and $x + y + z - 3 = 0$.

The vectors $\mathbf{N}_1 = (3, 2, -1)$ and $\mathbf{N}_2 = (1, 1, 1)$ are normal to P_1 and P_2 and parallel to P. Their cross product is

$$\mathbf{N} = \mathbf{N}_1 \times \mathbf{N}_2 = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 3 & 2 & -1 \\ 1 & 1 & 1 \end{vmatrix} = 3\mathbf{i} - 4\mathbf{j} + 1\mathbf{k}.$$

The vector $\mathbf{N}$ is perpendicular to the desired plane P, which therefore satisfies the equation

$$3(x-2) - 4(y+1) + (z-1) = 0 \qquad \text{or} \qquad 3x - 4y + z - 11 = 0.$$

► **Equation of the plane passing through two points and perpendicular to a given plane.** The plane passing through two points $M_1(x_1, y_1, z_1)$ and $M_2(x_2, y_2, z_2)$ and perpendicular to the plane $Ax + By + Cz + D = 0$ (see Fig. M4.22) is determined by the equation

$$\begin{vmatrix} x-x_1 & y-y_1 & z-z_1 \\ x_2-x_1 & y_2-y_1 & z_2-z_1 \\ A & B & C \end{vmatrix} = 0, \qquad \text{or} \qquad \bigl[(\mathbf{r}-\mathbf{r}_1)(\mathbf{r}_2-\mathbf{r}_1)\mathbf{N}\bigr] = 0, \qquad \text{(M4.5.1.5)}$$

where $\mathbf{r}$, $\mathbf{r}_1$, and $\mathbf{r}_2$ are the position vectors of the points $M(x, y, z)$, $M_1(x_1, y_1, z_1)$, and $M_2(x_2, y_2, z_2)$, respectively.

Remark. If the straight line passing through the points $M_1(x_1, y_1, z_1)$ and $M_2(x_2, y_2, z_2)$ is perpendicular to the original plane, then the desired plane is undetermined and equations (M4.5.1.5) become identities.

► **Equation of the plane passing through a point and perpendicular to two planes.** The plane passing through a point $M_1(x_1, y_1, z_1)$ and perpendicular to two (nonparallel)

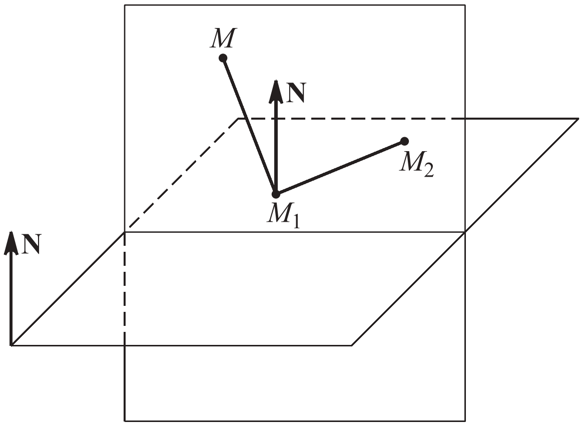

Figure M4.22. Plane passing through two points and perpendicular to a given plane.

planes $A_1x+B_1y+C_1z+D_1=0$ and $A_2x+B_2y+C_2z+D_2=0$ (see Fig. M4.23) is given by the equation

$$\begin{vmatrix} x-x_1 & y-y_1 & z-z_1 \\ A_1 & B_1 & C_1 \\ A_2 & B_2 & C_2 \end{vmatrix}=0, \qquad \text{or} \qquad \big[(\mathbf{r}-\mathbf{r}_1)\mathbf{N}_1\mathbf{N}_2\big]=0, \qquad \text{(M4.5.1.6)}$$

where $\mathbf{N}_1=(A_1,B_1,C_1)$ and $\mathbf{N}_2=(A_2,B_2,C_2)$ are normals to the given planes and $\mathbf{r}$ and $\mathbf{r}_1$ are the position vectors of the points $M(x,y,z)$ and $M_1(x_1,y_1,z_1)$, respectively.

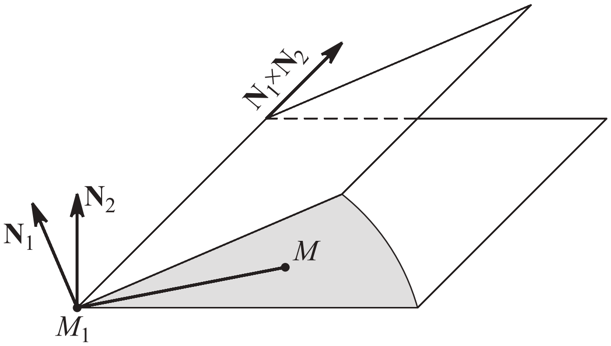

Figure M4.23. Plane passing through a point and perpendicular to two planes.

Remark 1. Equations (M4.5.1.6) mean that the vectors $\overrightarrow{M_1M}$, $\mathbf{N}_1$, and $\mathbf{N}_2$ are coplanar.

Remark 2. If the original planes are parallel, then the desired plane is undetermined. In this case, equations (M4.5.1.6) become identities.

Example 4. Let us find an equation of the plane passing through the point $M_1(0,1,2)$ and perpendicular to the planes $x-y+z-3=0$ and $-x+y+z+4=0$.

According to (M4.5.1.6), we have

$$\begin{vmatrix} x-0 & y-1 & z-2 \\ 1 & -1 & 1 \\ -1 & 1 & 1 \end{vmatrix}=0,$$

whence the desired equation is $x+y-1=0$.

► **Equation of planes passing through the line of intersection of planes.** The planes passing through the line of intersection of the planes $A_1x + B_1y + C_1z + D_1 = 0$ and $A_2x + B_2y + C_2z + D_2 = 0$ are given by the equation

$$\alpha(A_1x + B_1y + C_1z + D_1) + \beta(A_2x + B_2y + C_2z + D_2) = 0,$$

which is called the *equation of a pencil of planes*. Here α and β are arbitrary parameters ($\alpha^2 + \beta^2 \neq 0$).

M4.5.2. Line in Space

► **Parametric equations of a straight line.** The *parametric equations of the line* that passes through a point $M_1(x_1, y_1, z_1)$ and is parallel to a direction vector $\mathbf{R} = (l, m, n)$ (see Fig. M4.24) are

$$x = x_1 + lt, \quad y = y_1 + mt, \quad z = z_1 + nt, \qquad \text{or} \qquad \mathbf{r} = \mathbf{r}_1 + t\mathbf{R}, \qquad \text{(M4.5.2.1)}$$

where $\mathbf{r} = \overrightarrow{OM}$ and $\mathbf{r}_1 = \overrightarrow{OM}_1$. As the parameter t varies from $-\infty$ to $+\infty$, the point M with position vector $\mathbf{r} = (x, y, z)$ determined by formula (M4.5.2.1) runs over the entire straight line in question. It is convenient to use parametric equations (M4.5.2.1) if one needs to find the point of intersection of a straight line with a plane.

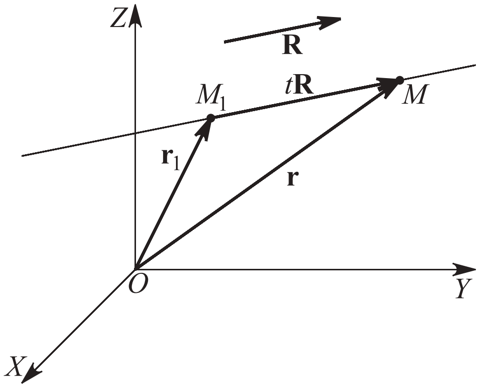

Figure M4.24. Straight line passing through a point and parallel to a direction vector.

The numbers l, m, and n characterize the direction of the straight line in space; they are called the *direction coefficients* of the straight line. For a unit vector $\mathbf{R} = \mathbf{R}^0$, the coefficients l, m, n are the cosines of the angles α, β, and γ formed by this straight line (the direction vector $\mathbf{R}^0$) with the coordinate axes OX, OY, and OZ. These cosines can be expressed via the coordinates of the direction vector $\mathbf{R}$ as

$$\cos\alpha = \frac{l}{\sqrt{l^2 + m^2 + n^2}}, \quad \cos\beta = \frac{m}{\sqrt{l^2 + m^2 + n^2}}, \quad \cos\gamma = \frac{n}{\sqrt{l^2 + m^2 + n^2}}.$$

► **Canonical equations of a straight line.** The equations

$$\frac{x - x_1}{l} = \frac{y - y_1}{m} = \frac{z - z_1}{n}, \qquad \text{or} \qquad (\mathbf{r} - \mathbf{r}_1) \times \mathbf{R} = 0, \qquad \text{(M4.5.2.2)}$$

are called the *canonical equations of the straight line* through the point $M_1(x_1, y_1, z_1)$ with the position vector $\mathbf{r}_1 = (x_1, y_1, z_1)$ and parallel to the direction vector $\mathbf{R} = (l, m, n)$.

Remark 1. One can obtain canonical equations (M4.5.2.2) from parametric equations (M4.5.2.1) by eliminating the parameter t.

Remark 2. In the canonical equations, all coefficients l, m, and n cannot be zero simultaneously, since $|\mathbf{R}| \neq 0$. But some of them may be zero. If one of the denominators in equations (M4.5.2.2) is zero, this means that the corresponding numerator is also zero.

► **General equation of a straight line.** The *general equation of a straight line in space* defines it as the line of intersection of two planes (see Fig. M4.25) and is given analytically by a system of two linear equations

$$\begin{aligned} A_1x + B_1y + C_1z + D_1 &= 0,\\ A_2x + B_2y + C_2z + D_2 &= 0. \end{aligned} \qquad \text{(M4.5.2.3)}$$

The normals to the planes are $\mathbf{N}_1 = (A_1, B_1, C_1)$ and $\mathbf{N}_2 = (A_2, B_2, C_2)$. The direction vector $\mathbf{R}$ is equal to the cross product of the normals $\mathbf{N}_1$ and $\mathbf{N}_2$; i.e.,

$$\mathbf{R} = \mathbf{N}_1 \times \mathbf{N}_2, \qquad \text{(M4.5.2.4)}$$

and its coordinates l, m, and n can be obtained by the formulas

$$l = \begin{vmatrix} B_1 & C_1 \\ B_2 & C_2 \end{vmatrix}, \quad m = \begin{vmatrix} C_1 & A_1 \\ C_2 & A_2 \end{vmatrix}, \quad n = \begin{vmatrix} A_1 & B_1 \\ A_2 & B_2 \end{vmatrix}.$$

Remark 1. Simultaneous equations of the form (M4.5.2.3) define a straight line if and only if the coefficients A_1, B_1, and C_1 in one of them are not proportional to the respective coefficients A_2, B_2, and C_2 in the other.

Remark 2. For $D_1 = D_2 = 0$ (and only in this case), the line passes through the origin.

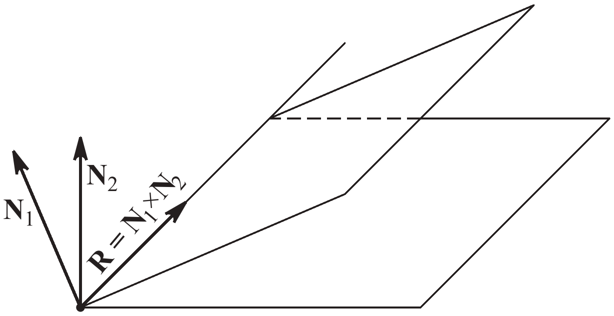

Figure M4.25. Straight line as intersection of two planes.

Example. Let us reduce the equation of the straight line

$$x + 2y - z + 1 = 0, \quad x - y + z + 3 = 0$$

to canonical form.

We choose one of the coordinates arbitrarily; say, $x = 0$. Then

$$2y - z + 1 = 0, \quad -y + z + 3 = 0,$$

and hence $y = -4$, $z = -7$. Thus the desired line contains the point $M(0, -4, -7)$. We find the cross product of the vectors $\mathbf{N}_1 = (1, 2, -1)$ and $\mathbf{N}_2 = (1, -1, 1)$ and, according to (M4.5.2.4), obtain the direction vector $\mathbf{R} = (1, -2, -3)$ of the desired line. Therefore, with (M4.5.2.2) taken into account, the equations of the line become

$$\frac{x}{1} = \frac{y+4}{-2} = \frac{z+7}{-3}.$$

► **Equations of a straight line passing through two points.** The canonical equations of the straight line (see Fig. M4.26) passing through two points $M_1(x_1, y_1, z_1)$ and $M_2(x_2, y_2, z_2)$ are

$$\frac{x-x_1}{x_2-x_1} = \frac{y-y_1}{y_2-y_1} = \frac{z-z_1}{z_2-z_1}, \qquad \text{or} \qquad (\mathbf{r}-\mathbf{r}_1)\times(\mathbf{r}_2-\mathbf{r}_1) = 0, \tag{M4.5.2.5}$$

where $\mathbf{r}$, $\mathbf{r}_1$, and $\mathbf{r}_2$ are the position vectors of the points $M(x, y, z)$, $M_1(x_1, y_1, z_1)$, and $M_2(x_2, y_2, z_2)$, respectively.

The parametric equations of this line are

$$\begin{aligned} x &= x_1(1-t) + x_2 t,\\ y &= y_1(1-t) + y_2 t,\\ z &= z_1(1-t) + z_2 t, \end{aligned} \qquad \text{or} \qquad \mathbf{r} = (1-t)\mathbf{r}_1 + t\mathbf{r}_2. \tag{M4.5.2.6}$$

Remark. Eliminating the parameter t from equations (M4.5.2.6), we obtain equations (M4.5.2.5).

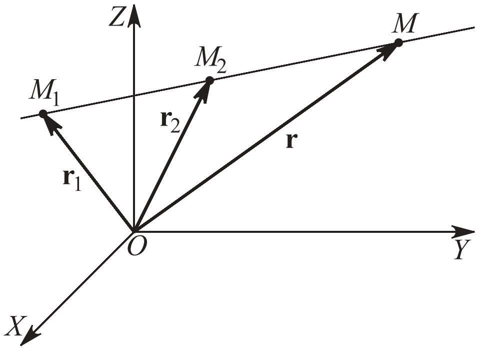

Figure M4.26. Straight line passing through two points.

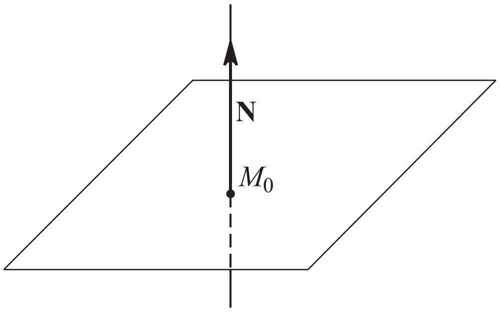

Figure M4.27. Straight line passing through a point and perpendicular to a plane.

► **Equations of a straight line passing through a point and perpendicular to a plane.** The equations of the straight line passing through a point $M_0(x_0, y_0, z_0)$ and perpendicular to the plane given by the equation $Ax + By + Cz + D = 0$ (see Fig. M4.27) are

$$\frac{x-x_0}{A} = \frac{y-y_0}{B} = \frac{z-z_0}{C}.$$

M4.5.3. Mutual Arrangement of Points, Lines, and Planes

► **Angles between lines in space.** Consider two straight lines determined by vector parametric equations $\mathbf{r} = \mathbf{r}_1 + t\mathbf{R}_1$ and $\mathbf{r} = \mathbf{r}_2 + t\mathbf{R}_2$. The angle φ between these lines (see Fig. M4.28) can be obtained from the formulas

$$\cos\varphi = \frac{\mathbf{R}_1\cdot\mathbf{R}_2}{|\mathbf{R}_1|\,|\mathbf{R}_2|}, \qquad \sin\varphi = \frac{|\mathbf{R}_1\times\mathbf{R}_2|}{|\mathbf{R}_1|\,|\mathbf{R}_2|}.$$

If the lines are given by the canonical equations

$$\frac{x-x_1}{l_1} = \frac{y-y_1}{m_1} = \frac{z-z_1}{n_1} \quad \text{and} \quad \frac{x-x_2}{l_2} = \frac{y-y_2}{m_2} = \frac{z-z_2}{n_2}, \tag{M4.5.3.1}$$

then the angle φ between the lines can be found from the formulas

$$\cos\varphi=\frac{l_1l_2+m_1m_2+n_1n_2}{\sqrt{l_1^2+m_1^2+n_1^2}\sqrt{l_2^2+m_2^2+n_2^2}},$$
$$\sin\varphi=\frac{\sqrt{\begin{vmatrix} m_1 & n_1\\ m_2 & n_2\end{vmatrix}^2+\begin{vmatrix} n_1 & l_1\\ n_2 & l_2\end{vmatrix}^2+\begin{vmatrix} l_1 & m_1\\ l_2 & m_2\end{vmatrix}^2}}{\sqrt{l_1^2+m_1^2+n_1^2}\sqrt{l_2^2+m_2^2+n_2^2}}. \qquad \text{(M4.5.3.2)}$$

Example 1. Let us find the angle between the lines

$$\frac{x}{1}=\frac{y-2}{2}=\frac{z+1}{2} \quad\text{and}\quad \frac{x}{0}=\frac{y-2}{3}=\frac{z+1}{4}.$$

Using the first formula in (M4.5.3.2), we obtain

$$\cos\varphi=\frac{1\cdot0+2\cdot3+2\cdot4}{\sqrt{1^2+2^2+2^2}\,\sqrt{0^2+3^2+4^2}}=\frac{14}{15},$$

and hence $\varphi\approx0.3672$ rad.

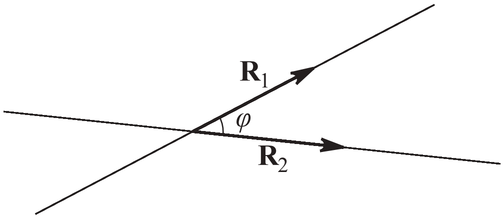

Figure M4.28. Angle between two lines in space.

► **Conditions for two lines to be parallel.** Two straight lines given by vector parametric equations $\mathbf{r}=\mathbf{r}_1+t\mathbf{R}_1$ and $\mathbf{r}=\mathbf{r}_2+t\mathbf{R}_2$ are parallel if

$$\mathbf{R}_2=\lambda\mathbf{R}_1 \qquad\text{or}\qquad \mathbf{R}_2\times\mathbf{R}_1=0,$$

i.e., if their direction vectors $\mathbf{R}_1$ and $\mathbf{R}_2$ are collinear. This can be written as

$$\frac{l_1}{l_2}=\frac{m_1}{m_2}=\frac{n_1}{n_2}.$$

Remark. If parallel lines have a common point (i.e., $\mathbf{r}_1=\mathbf{r}_2$ in parametric equations), then they coincide.

► **Conditions for two lines to be perpendicular.** Two straight lines given by vector parametric equations $\mathbf{r}=\mathbf{r}_1+t\mathbf{R}_1$ and $\mathbf{r}=\mathbf{r}_2+t\mathbf{R}_2$ are perpendicular if

$$\mathbf{R}_1\cdot\mathbf{R}_2=0. \qquad \text{(M4.5.3.3)}$$

This condition can be written as

$$l_1l_2+m_1m_2+n_1n_2=0. \qquad \text{(M4.5.3.4)}$$

Example 2. Let us show that the lines

$$\frac{x-1}{2}=\frac{y-3}{1}=\frac{z}{2} \quad\text{and}\quad \frac{x-2}{1}=\frac{y+1}{2}=\frac{z}{-2}$$

are perpendicular.

Indeed, condition (M4.5.3.4) is satisfied,

$$2\cdot1+1\cdot2+2\cdot(-2)=0,$$

and hence the lines are perpendicular.

► **Theorem on the arrangement of two lines in space.** *Two straight lines in space can:*
a) *be skew;*
b) *lie in the same plane and not meet each other, i.e., be parallel;*
c) *meet at a point;*
d) *coincide.*

A general characteristic of all four cases is the determinant of the matrix

$$\begin{pmatrix} x_2 - x_1 & y_2 - y_1 & z_2 - z_1 \\ l_1 & m_1 & n_1 \\ l_2 & m_2 & n_2 \end{pmatrix}, \qquad \text{(M4.5.3.5)}$$

whose entries are taken from the canonical equations of the lines (M4.5.3.1).

In cases *a*–*d* of the theorem, for the matrix (M4.5.3.5) we have, respectively:
a) the determinant is nonzero;
b) the last two rows are proportional to each other but are not proportional to the first row;
c) the last two rows are not proportional, and the first row is their linear combination;
d) all rows are proportional.

In cases *b*–*d* the determinant is zero.

► **Angle between planes.** Consider two planes given by the general equations

$$\begin{aligned} A_1x + B_1y + C_1z + D_1 &= 0, \\ A_2x + B_2y + C_2z + D_2 &= 0. \end{aligned} \qquad \text{(M4.5.3.6)}$$

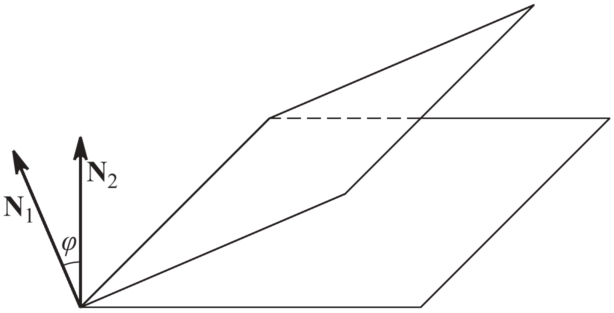

Figure M4.29. Angle between two planes.

The angle between two planes (see Fig. M4.29) is defined as any of the two adjacent dihedral angles formed by the planes (if the planes are parallel, then the angle between them is by definition equal to 0 or π). One of these dihedral angles is equal to the angle φ between the normal vectors $\mathbf{N}_1 = (A_1, B_1, C_1)$ and $\mathbf{N}_2 = (A_2, B_2, C_2)$ to the planes, which can be determined by the formula

$$\cos\varphi = \frac{A_1A_2 + B_1B_2 + C_1C_2}{\sqrt{A_1^2 + B_1^2 + C_1^2}\sqrt{A_2^2 + B_2^2 + C_2^2}} = \frac{\mathbf{N}_1 \cdot \mathbf{N}_2}{|\mathbf{N}_1|\,|\mathbf{N}_2|}.$$

► **Conditions for two planes to be parallel.** Two planes given by the general equations (M4.5.3.6) are parallel if and only if the following *condition for the planes to be parallel* is satisfied:

$$\frac{A_1}{A_2} = \frac{B_1}{B_2} = \frac{C_1}{C_2} \neq \frac{D_1}{D_2};$$

in this case, the planes do not coincide.

Two planes coincide if they are parallel and have a common point. Two planes given by the general equations (M4.5.3.6) coincide if and only if the following *condition for the planes to coincide* is satisfied:

$$\frac{A_1}{A_2} = \frac{B_1}{B_2} = \frac{C_1}{C_2} = \frac{D_1}{D_2}.$$

► **Conditions for two planes to be perpendicular.** Planes are perpendicular if their normals are perpendicular. Two planes determined by the general equations (M4.5.3.6) are perpendicular if and only if the following *condition for the planes to be perpendicular* is satisfied:

$$A_1A_2 + B_1B_2 + C_1C_2 = 0 \qquad \text{or} \qquad \mathbf{N}_1\cdot\mathbf{N}_2 = 0, \tag{M4.5.3.7}$$

where $\mathbf{N}_1 = (A_1, B_1, C_1)$ and $\mathbf{N}_2 = (A_2, B_2, C_2)$ are the normals to the planes.

Example 3. Let us show that the planes $x - y + z = 0$ and $x - y - 2z + 5 = 0$ are perpendicular.
Since condition (M4.5.3.7) is satisfied,

$$1\cdot 1 + (-1)\cdot(-1) + 1\cdot(-2) = 0,$$

we see that the planes are perpendicular.

► **Angle between a straight line and a plane.** Consider a plane given by the general equation

$$Ax + By + Cz + D = 0 \tag{M4.5.3.8}$$

and a line given by the canonical equations

$$\frac{x - x_1}{l} = \frac{y - y_1}{m} = \frac{z - z_1}{n}. \tag{M4.5.3.9}$$

The angle between the line and the plane (see Fig. M4.30) is defined as the complementary angle θ of the angle φ between the direction vector $\mathbf{R} = (l, m, n)$ of the line and the normal $\mathbf{N} = (A, B, C)$ to the plane. For this angle, one has the formula

$$\sin\theta = |\cos\varphi| = \frac{|Al + Bm + Cn|}{\sqrt{A^2 + B^2 + C^2}\sqrt{l^2 + m^2 + n^2}} = \frac{|\mathbf{N}\cdot\mathbf{R}|}{|\mathbf{N}|\,|\mathbf{R}|}.$$

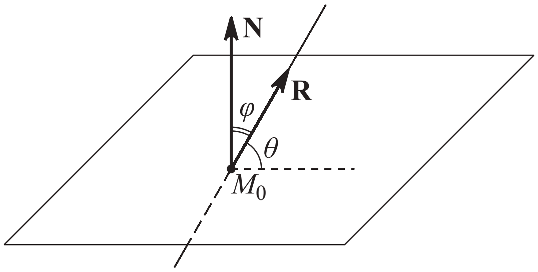

Figure M4.30. Angle between a straight line and a plane.

► **Conditions for a straight line and a plane to be parallel.** A plane given by the general equation (M4.5.3.8) and a line given by canonical equations (M4.5.3.9) are parallel if the following two conditions hold:

$$Al + Bm + Cn = 0,$$
$$Ax_1 + By_1 + Cz_1 + D \neq 0.$$

The first condition means that the direction vector of the straight line is perpendicular to the normal to the plane and the second condition means that the line is not contained in the plane.

▶ **Condition for a straight line and a plane to be perpendicular.** A line given by canonical equations (M4.5.3.9) and a plane given by the general equation (M4.5.3.8) are perpendicular if the line is collinear to the normal to the plane (is a normal itself), i.e., if

$$\frac{A}{l}=\frac{B}{m}=\frac{C}{n},\qquad \text{or}\qquad \mathbf{N}=\lambda\mathbf{R}.$$

▶ **Intersection of a straight line and a plane.** Consider a plane given by the general equation (M4.5.3.8) and a straight line given by parametric equations

$$x=x_1+lt,\quad y=y_1+mt,\quad z=z_1+nt.$$

The coordinates of the point $M_0(x_0,y_0,z_0)$ of intersection of the line with the plane (see Fig. M4.30), if the point exists at all, are determined by the formulas

$$x_0=x_1+lt_0,\quad y_0=y_1+mt_0,\quad z_0=z_1+nt_0,$$

where

$$t_0=-\frac{Ax_1+By_1+Cz_1+D}{Al+Bm+Cn}.$$

▶ **Distance from a point to a plane.** The distance from a point $M_0(x_0,y_0,z_0)$ to a plane given by the general equation (M4.5.1.1) is determined by the formula

$$d=\frac{|Ax_0+By_0+Cz_0+D|}{\sqrt{A^2+B^2+C^2}}.$$

▶ **Distance between two parallel planes.** We consider two parallel planes given by the general equations $Ax+By+Cz+D_1=0$ and $Ax+By+Cz+D_2=0$. The distance between them is

$$d=\frac{|D_1-D_2|}{\sqrt{A^2+B^2+C^2}}.$$

▶ **Distance from a point to a straight line.** The distance from a point $M_0(x_0,y_0,z_0)$ to a line given by canonical equations (M4.5.2.2) is determined by the formula

$$d=\frac{\sqrt{\begin{vmatrix} m & n\\ y_1-y_0 & z_1-z_0\end{vmatrix}^2+\begin{vmatrix} n & l\\ z_1-z_0 & x_1-x_0\end{vmatrix}^2+\begin{vmatrix} l & m\\ x_1-x_0 & y_1-y_0\end{vmatrix}^2}}{\sqrt{l^2+m^2+n^2}}.$$

▶ **Distance between straight lines.** Consider two nonparallel lines given in the canonical form

$$\frac{x-x_1}{l_1}=\frac{y-y_1}{m_1}=\frac{z-z_1}{n_1},$$
$$\frac{x-x_2}{l_2}=\frac{y-y_2}{m_2}=\frac{z-z_2}{n_2}.$$

The distance between them can be calculated by the formula

$$d=\frac{\pm\begin{vmatrix} x_1-x_2 & y_1-y_2 & z_1-z_2\\ l_1 & m_1 & n_1\\ l_2 & m_2 & n_2\end{vmatrix}}{\sqrt{\begin{vmatrix} l_1 & m_1\\ l_2 & m_2\end{vmatrix}^2+\begin{vmatrix} m_1 & n_1\\ m_2 & n_2\end{vmatrix}^2+\begin{vmatrix} n_1 & l_1\\ n_2 & l_2\end{vmatrix}^2}}\tag{M4.5.3.10}$$

(minus sign should be taken if the determinant is negative). The condition that the determinant in the numerator in (M4.5.3.10) is zero is the *condition for the two lines in space to meet*.

M4.6. Quadric Surfaces (Quadrics)

M4.6.1. Quadrics and Their Canonical Equations

► **Central surfaces.** A segment joining two points of a surface is called a *chord*. If there exists a point in space, not necessarily lying on the surface, that bisects all chords passing through it, then the surface is said to be *central* and the point is called the *center* of the surface.

The equations listed below for central surfaces are given in *canonical form*; i.e., the center of a surface is at the origin, and the surface symmetry axes are the coordinate axes. Moreover, the coordinate planes are symmetry planes.

► **Ellipsoid.** An *ellipsoid* is a central surface defined by the equation

$$\frac{x^2}{a^2}+\frac{y^2}{b^2}+\frac{z^2}{c^2}=1, \tag{M4.6.1.1}$$

where the numbers a, b, and c are the lengths of the segments called the *semiaxes* of the ellipsoid (see Fig. M4.31 *a*). The coordinates of all points of the ellipsoid satisfy the inequalities $-a \le x \le a$, $-b \le y \le b$, and $-c \le z \le c$.

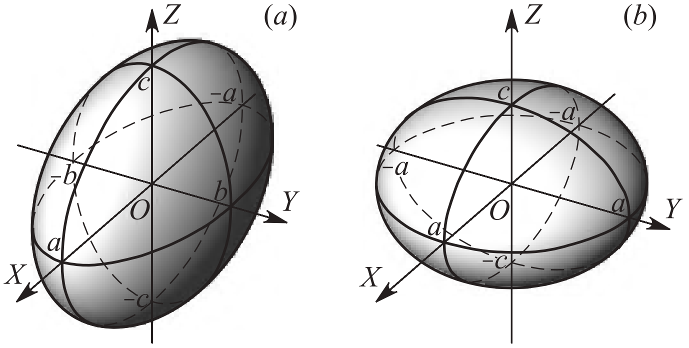

Figure M4.31. Triaxial ellipsoid (*a*) and spheroid (*b*).

If $a \ne b \ne c$, then the ellipsoid is said to be *triaxial*, or *scalene*. If $a = b \ne c$, then the ellipsoid is called a *spheroid*; it can be obtained by rotating the ellipse $x^2/a^2 + z^2/c^2 = 1$, $y = 0$ lying in the plane OXZ about the axis OZ (see Fig. M4.31 *b*). If $a = b > c$, then the ellipsoid is an *oblate spheroid*, and if $a = b < c$, then the ellipsoid is a *prolate spheroid*. If $a = b = c$, then the ellipsoid is the sphere of radius a given by the equation $x^2 + y^2 + z^2 = a^2$.

An arbitrary plane section of an ellipsoid is an ellipse (or, in a special case, a circle).

The volume of an ellipsoid is equal to $V = \frac{4}{3}\pi abc$.

Remark. About the sphere, see also Subsection M3.2.3.

► **Hyperboloids.** A *one-sheeted hyperboloid* is a central surface defined by the equation

$$\frac{x^2}{a^2}+\frac{y^2}{b^2}-\frac{z^2}{c^2}=1, \tag{M4.6.1.2}$$

where a and b are the *real semiaxes* and c is the *imaginary semiaxis* (see Fig. M4.32 *a*).

A *two-sheeted hyperboloid* is a central surface defined by the equation

$$\frac{x^2}{a^2}+\frac{y^2}{b^2}-\frac{z^2}{c^2}=-1, \tag{M4.6.1.3}$$

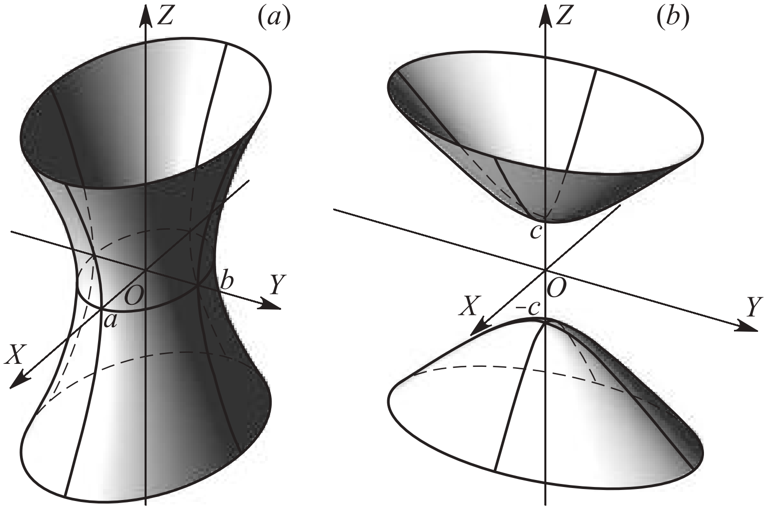

Figure M4.32. One-sheeted (*a*) and two-sheeted (*b*) hyperboloids.

where c is the *real semiaxis* and a and b are the *imaginary semiaxes* (see Fig. M4.32 *b*). A two-sheeted hyperboloid consists of two parts whose points lie at $z \le -c$ and $z \ge c$.

A hyperboloid approaches the surface

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} - \frac{z^2}{c^2} = 0,$$

which is called an *asymptotic cone*, infinitely closely.

A plane passing through the axis OZ intersects each of the hyperboloids (M4.6.1.2) and (M4.6.1.3) in two hyperbolas and the asymptotic cone in two straight lines, which are the asymptotes of these hyperbolas. The section of a hyperboloid by a plane parallel to OXY is an ellipse. The section of a one-sheeted hyperboloid by the plane $z = 0$ is an ellipse, which is called the *gorge* or *throat* ellipse.

For $a = b$, we deal with the *hyperboloid of revolution* obtained by rotating a hyperbola with semiaxes a and c about its focal axis $2c$ (which is an imaginary axis for a one-sheeted hyperboloid and a real axis for a two-sheeted hyperboloid). If $a = b = c$, then the hyperboloid of revolution is said to be *right*, and its sections by the planes OXZ and OYZ are equilateral hyperbolas.

► **Cone.** A *cone* is a central surface defined by the equation

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} - \frac{z^2}{c^2} = 0. \qquad \text{(M4.6.1.4)}$$

The cone (see Fig. M4.33) defined by (M4.6.1.4) has vertex at the origin, and for its base we can take the ellipse with semiaxes a and b in the plane perpendicular to the axis OZ at the distance c from the origin. This cone is the asymptotic cone for the hyperboloids (M4.6.1.2) and (M4.6.1.3). For $a = b$, we obtain a *right circular cone*.

Remark. About the cone, see also Subsection M3.2.3.

► **Paraboloids.** In contrast to the surfaces considered above, paraboloids are not central surfaces. For the equations listed below, the vertex of a paraboloid lies at the origin, the axis OZ is the symmetry axis, and the planes OXZ and OYZ are symmetry planes.

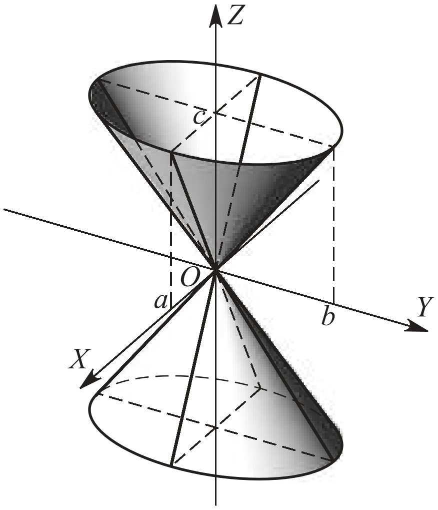

Figure M4.33. A cone.

An *elliptic paraboloid* (see Fig. M4.34 *a*) is a noncentral surface defined by the equation

$$\frac{x^2}{p} + \frac{y^2}{q} = 2z, \qquad \text{(M4.6.1.5)}$$

where $p > 0$ and $q > 0$ are parameters. All points of an elliptic paraboloid lie in the domain $z \geq 0$.

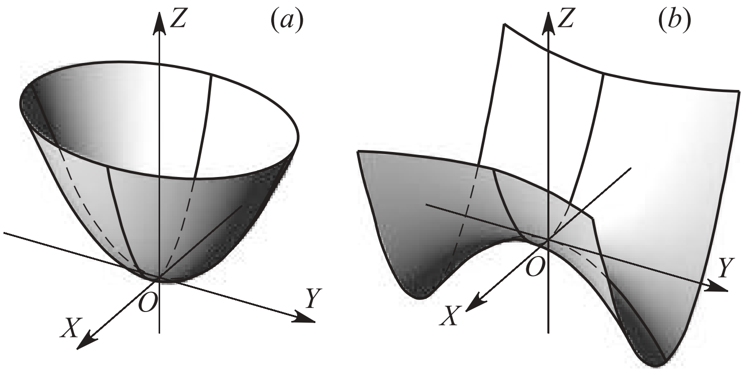

Figure M4.34. Elliptic (*a*) and hyperbolic (*b*) paraboloids.

The sections of an elliptic paraboloid by planes parallel to the axis OZ are parabolas, and the sections by planes parallel to the plane OXY are ellipses. If $p = q$, then we have a *paraboloid of revolution*, which is obtained by rotating the parabola $2pz = x^2$ lying in the plane OXZ about its axis.

The volume of the part of an elliptic paraboloid cut by the plane perpendicular to its axis at a height h is equal to $V = \frac{1}{2}\pi abh$, i.e., half the volume of the elliptic cylinder with the same base and altitude.

A *hyperbolic paraboloid* (see Fig. M4.34 *b*) is a noncentral surface defined by the equation

$$\frac{x^2}{p} - \frac{y^2}{q} = 2z, \tag{M4.6.1.6}$$

where $p > 0$ and $q > 0$ are parameters.

The sections of a hyperbolic paraboloid by planes parallel to the axis OZ are parabolas, and the sections by planes parallel to the plane OXY are hyperbolas.

M4.6.2. Quadrics (General Theory)

► **General equation of a quadric. Translation and rotation.** A *quadric* is a set of points in three-dimensional space whose coordinates in the rectangular Cartesian coordinate system satisfy a second-order algebraic equation

$$a_{11}x^2+a_{22}y^2+a_{33}z^2+2a_{12}xy+2a_{13}xz+2a_{23}yz+2a_{14}x+2a_{24}y+2a_{34}z+a_{44}=0, \tag{M4.6.2.1}$$

or

$$\begin{aligned}&(a_{11}x + a_{12}y + a_{13}z + a_{14})x + (a_{21}x + a_{22}y + a_{23}z + a_{24})y\\ &\qquad + (a_{31}x + a_{32}y + a_{33}z + a_{34})z + a_{41}x + a_{42}y + a_{43}z + a_{44} = 0,\end{aligned}$$

with symmetric coefficients, $a_{ij} = a_{ji}$ $(i, j = 1, 2, 3, 4)$; the factors 2 appearing in some terms are introduced for further convenience. If equation (M4.6.2.1) does not define a real geometric object, then one says that this equation defines an *imaginary quadric*.

Equation (M4.6.2.1) can be simplified using the transformations of translation and rotation.

1. Translation:

$$x = \bar{x} + x_0, \quad y = \bar{y} + y_0, \quad z = \bar{z} + z_0. \tag{M4.6.2.2}$$

This transformation means that the origin $O(0, 0, 0)$ is translated to the point $\bar{O}(x_0, y_0, z_0)$ with the new axes of coordinates remaining parallel to the original ones; $\bar{x}$, $\bar{y}$, and $\bar{z}$ are the new coordinates.

2. Rotation:

$$x = e_{11}\hat{x} + e_{12}\hat{y} + e_{13}\hat{z}, \quad y = e_{21}\hat{x} + e_{22}\hat{y} + e_{23}\hat{z}, \quad z = e_{31}\hat{x} + e_{32}\hat{y} + e_{33}\hat{z}. \tag{M4.6.2.3}$$

This transformation means that all points are rotated about the origin O, with e_{11}, e_{21}, e_{31} being the direction cosines of the axis $O\widehat{X}$, e_{12}, e_{22}, e_{32} those of the axis $O\widehat{Y}$, and e_{13}, e_{23}, e_{33} those of the axis $O\widehat{Z}$ in the initial coordinate system $OXYZ$.

► **Classification of quadrics.** With successive application of transformations (M4.6.2.2)–(M4.6.2.3), equation (M4.6.2.1) can be reduced to one of the following 17 *canonical forms*, each of which is associated with a certain class of quadrics (see Table M4.2). The first six surfaces, with $\delta \neq 0$, are *nondegenerate*; their canonical equations contain three quadratic terms proportional to x^2, y^2, and z^2. The other surfaces, 7–17, with $\delta = 0$, are *degenerate*; their canonical equations contain only two (proportional to x^2 and y^2) or even one (x^2) quadratic term. The last five surfaces, 13–17, disintegrate into planes (real or imaginary); their equations can be represented as the product of two factors linear in coordinates on the left-hand side and zero on the right-hand side.

TABLE M4.2
Classification of quadrics.

No.	Surface	Canonical equation	Conditions for invariants
1	Ellipsoid	$\frac{x^2}{a^2}+\frac{y^2}{b^2}+\frac{z^2}{c^2}=1$	$\delta\neq 0,\ \Delta<0,\ S\delta>0,\ T>0$
2	Imaginary ellipsoid	$\frac{x^2}{a^2}+\frac{y^2}{b^2}+\frac{z^2}{c^2}=-1$	$\delta\neq 0,\ \Delta>0,\ S\delta>0,\ T>0$
3	Imaginary cone with real vertex	$\frac{x^2}{a^2}+\frac{y^2}{b^2}+\frac{z^2}{c^2}=0$	$\delta\neq 0,\ \Delta=0,\ S\delta>0,\ T>0$
4	One-sheeted hyperboloid	$\frac{x^2}{a^2}+\frac{y^2}{b^2}-\frac{z^2}{c^2}=1$	$\delta\neq 0,\ \Delta>0,$ $S\delta>0$ or $T>0$ (not both >0)
5	Two-sheeted hyperboloid	$\frac{x^2}{a^2}+\frac{y^2}{b^2}-\frac{z^2}{c^2}=-1$	$\delta\neq 0,\ \Delta<0,$ $S\delta>0$ or $T>0$ (not both >0)
6	Real cone	$\frac{x^2}{a^2}+\frac{y^2}{b^2}-\frac{z^2}{c^2}=0$	$\delta\neq 0,\ \Delta=0,$ $S\delta>0$ or $T>0$ (not both >0)
7	Elliptic paraboloid	$\frac{x^2}{p}+\frac{y^2}{q}=2z\quad(p,q>0)$	$\delta=0,\ \Delta<0,\ T>0$
8	Hyperbolic paraboloid	$\frac{x^2}{p}-\frac{y^2}{q}=2z\quad(p,q>0)$	$\delta=0,\ \Delta>0,\ T<0$
9	Elliptic cylinder	$\frac{x^2}{a^2}+\frac{y^2}{b^2}=1$	$\delta=\Delta=0,\ T>0,\ S\sigma<0$
10	Imaginary elliptic cylinder	$\frac{x^2}{a^2}+\frac{y^2}{b^2}=-1$	$\delta=\Delta=0,\ T>0,\ S\sigma>0$
11	Hyperbolic cylinder	$\frac{x^2}{a^2}-\frac{y^2}{b^2}=1$	$\delta=\Delta=0,\ T<0,\ \sigma\neq 0$
12	Parabolic cylinder	$y^2=2px$	$\delta=\Delta=0,\ T=0$
13	Pair of real intersecting planes	$\frac{x^2}{a^2}-\frac{y^2}{b^2}=0$	$\delta=\Delta=0,\ T<0,\ \sigma=0$
14	Pair of imaginary planes intersecting in a real straight line	$\frac{x^2}{a^2}+\frac{y^2}{b^2}=0$	$\delta=\Delta=0,\ T>0,\ \sigma=0$
15	Pair of real parallel planes	$x^2=a^2$	$\delta=\Delta=T=0,\ \Sigma<0$
16	Pair of imaginary parallel planes	$x^2=-a^2$	$\delta=\Delta=T=0,\ \Sigma>0$
17	Pair of real coinciding planes	$x^2=0$	$\delta=\Delta=T=0,\ \Sigma=0$

► **Invariants of quadrics.** The shape of a quadric can be identified using four *invariants* and two *semi-invariants* without reducing equation (M4.6.2.1) to canonical form.

The four main invariants are

$$S=a_{11}+a_{22}+a_{33}, \tag{M4.6.2.4}$$

$$T=\begin{vmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{vmatrix}+\begin{vmatrix} a_{11} & a_{13} \\ a_{31} & a_{33} \end{vmatrix}+\begin{vmatrix} a_{22} & a_{23} \\ a_{32} & a_{33} \end{vmatrix}, \tag{M4.6.2.5}$$

$$\delta=\begin{vmatrix} a_{11} & a_{12} & a_{13} \\ a_{12} & a_{22} & a_{23} \\ a_{13} & a_{23} & a_{33} \end{vmatrix}, \tag{M4.6.2.6}$$

$$\Delta=\begin{vmatrix} a_{11} & a_{12} & a_{13} & a_{14} \\ a_{12} & a_{22} & a_{23} & a_{24} \\ a_{13} & a_{23} & a_{33} & a_{34} \\ a_{14} & a_{24} & a_{34} & a_{44} \end{vmatrix}, \tag{M4.6.2.7}$$

whose values are preserved under parallel translations and rotations of the coordinate axes.

The semi-invariants are

$$\sigma = \Delta_{11} + \Delta_{22} + \Delta_{33},$$
$$\Sigma = \begin{vmatrix} a_{11} & a_{14} \\ a_{41} & a_{44} \end{vmatrix} + \begin{vmatrix} a_{22} & a_{24} \\ a_{42} & a_{44} \end{vmatrix} + \begin{vmatrix} a_{33} & a_{34} \\ a_{43} & a_{44} \end{vmatrix},$$

whose values are preserved only under rotations of the coordinate axes, with Δ_{ij} being the cofactor of the entry a_{ij} in Δ.

The last column in Table M4.2 allows the classification of the quadrics in accordance with the values of the invariants S, T, δ, and Δ and semi-invariants σ and Σ.

► **Characteristic quadratic form of a quadric.** The *characteristic quadratic form*

$$F(x,y,z) = a_{11}x^2 + a_{22}y^2 + a_{33}z^2 + 2a_{12}xy + 2a_{13}xz + a_{23}yz$$

corresponding to equation (M4.6.2.1) and its *characteristic equation*

$$\begin{vmatrix} a_{11}-\lambda & a_{12} & a_{13} \\ a_{12} & a_{22}-\lambda & a_{23} \\ a_{13} & a_{23} & a_{33}-\lambda \end{vmatrix} = 0, \qquad \text{or} \qquad \lambda^3 - S\lambda^2 + T\lambda - \delta = 0 \qquad \text{(M4.6.2.8)}$$

permit studying the main properties of quadrics.

The roots λ_1, λ_2, and λ_3 of the characteristic equation (M4.6.2.8) are the eigenvalues of the real symmetric matrix $[a_{ij}]$ and hence are always real. The invariants S, T, and δ can be expressed in terms of the roots λ_1, λ_2, and λ_3 as follows:

$$S = \lambda_1 + \lambda_2 + \lambda_3, \quad T = \lambda_1\lambda_2 + \lambda_1\lambda_3 + \lambda_2\lambda_3, \quad \delta = \lambda_1\lambda_2\lambda_3.$$

The expressions of the parameters of the main quadrics via the invariants T, δ, and Δ and the roots λ_1, λ_2, and λ_3 of the characteristic equation are listed in Table M4.3.

TABLE M4.3

Expressions of the parameters of the main quadrics via the invariants (M4.6.2.4)–(M4.6.2.7) and the roots of the characteristic equation (M4.6.2.8).

Surface	Canonical equation	Parameters of the quadrics	Remarks
Ellipsoid	$\dfrac{x^2}{a^2} + \dfrac{y^2}{b^2} + \dfrac{z^2}{c^2} = 1$	$a^2 = -\dfrac{1}{\lambda_3}\dfrac{\Delta}{\delta}$, $b^2 = -\dfrac{1}{\lambda_2}\dfrac{\Delta}{\delta}$, $c^2 = -\dfrac{1}{\lambda_1}\dfrac{\Delta}{\delta}$, $\delta = \lambda_1\lambda_2\lambda_3$	$a \ge b \ge c$, $\lambda_1 \ge \lambda_2 \ge \lambda_3 > 0$
One-sheeted hyperboloid	$\dfrac{x^2}{a^2} + \dfrac{y^2}{b^2} - \dfrac{z^2}{c^2} = 1$	$a^2 = -\dfrac{1}{\lambda_2}\dfrac{\Delta}{\delta}$, $b^2 = -\dfrac{1}{\lambda_1}\dfrac{\Delta}{\delta}$, $c^2 = \dfrac{1}{\lambda_3}\dfrac{\Delta}{\delta}$, $\delta = \lambda_1\lambda_2\lambda_3$	$a \ge b$, $\lambda_1 \ge \lambda_2 > 0 > \lambda_3$
Two-sheeted hyperboloid	$\dfrac{x^2}{a^2} + \dfrac{y^2}{b^2} - \dfrac{z^2}{c^2} = -1$	$a^2 = \dfrac{1}{\lambda_3}\dfrac{\Delta}{\delta}$, $b^2 = \dfrac{1}{\lambda_2}\dfrac{\Delta}{\delta}$, $c^2 = -\dfrac{1}{\lambda_1}\dfrac{\Delta}{\delta}$, $\delta = \lambda_1\lambda_2\lambda_3$	$a \ge b$, $\lambda_1 > 0 > \lambda_2 \ge \lambda_3$
Elliptic paraboloid	$\dfrac{x^2}{p} + \dfrac{y^2}{q} = 2z$	$p = \dfrac{1}{\lambda_2}\sqrt{-\dfrac{\Delta}{T}}$, $q = \dfrac{1}{\lambda_1}\sqrt{-\dfrac{\Delta}{T}}$, $T = \lambda_1\lambda_2$	$p > 0$, $q > 0$, $\lambda_1 \ge \lambda_2 > \lambda_3 = 0$
Hyperbolic paraboloid	$\dfrac{x^2}{p} - \dfrac{y^2}{q} = 2z$	$p = \dfrac{1}{\lambda_1}\sqrt{-\dfrac{\Delta}{T}}$, $q = -\dfrac{1}{\lambda_3}\sqrt{-\dfrac{\Delta}{T}}$, $T = \lambda_1\lambda_3$	$p > 0$, $q > 0$, $\lambda_1 > \lambda_2 = 0 > \lambda_3$

Chapter M5

Algebra

M5.1. Polynomials and Algebraic Equations

M5.1.1. Polynomials and Their Properties

► **Definition of a polynomial.** A *polynomial of degree* n of a scalar variable x is an expression of the form

$$f(x) \equiv a_n x^n + a_{n-1} x^{n-1} + \cdots + a_1 x + a_0 \quad (a_n \neq 0), \tag{M5.1.1.1}$$

where $a_0, \ldots, a_n$ are real or complex numbers ($n = 0, 1, 2, \ldots$). Polynomials of degree zero are nonzero numbers.

Two polynomials are *equal* if they have the same coefficients of like powers of the variable.

► **Main operations over polynomials.**

1°. The *sum* (*difference*) of two polynomials $f(x)$ of degree n and $g(x)$ of degree m is the polynomial of degree $l \le \max\{n, m\}$ whose coefficient of each power of x is equal to the sum (difference) of the coefficients of the same power of x in $f(x)$ and $g(x)$, i.e., if

$$g(x) \equiv b_m x^m + b_{m-1} x^{m-1} + \cdots + b_1 x + b_0, \tag{M5.1.1.2}$$

then the sum (difference) of polynomials (M5.1.1.1) and (M5.1.1.2) is

$$f(x) \pm g(x) = c_l x^l + c_{l-1} x^{l-1} + \cdots + c_1 x + c_0, \quad \text{where} \quad c_k = a_k \pm b_k \quad (k = 0, 1, \ldots, l).$$

If $n > m$ then $b_{m+1} = \cdots = b_n = 0$; if $n < m$ then $a_{n+1} = \cdots = a_m = 0$.

2°. To *multiply* a polynomial $f(x)$ of degree n by a polynomial $g(x)$ of degree m, one should multiply each term in $f(x)$ by each term in $g(x)$, add the products, and collect similar terms. The degree of the resulting polynomial is $n+m$. The product of polynomials (M5.1.1.1) and (M5.1.1.2) is

$$f(x)g(x) = c_{n+m} x^{n+m} + c_{n+m-1} x^{n+m-1} + \cdots + c_1 x + c_0, \qquad c_k = \sum_{i,j=0}^{i+j=k} a_i b_j,$$

where $k = 0, 1, \ldots, n+m$.

3°. Each polynomial $f(x)$ of degree n can be *divided* by any other polynomial $p(x)$ of degree m ($p(x) \neq 0$) *with remainder*, i.e., uniquely represented in the form $f(x) = p(x)q(x) + r(x)$, where $q(x)$ is a polynomial of degree $n - m$ (for $m \le n$) or $q(x) = 0$ (for $m > n$), referred to as the *quotient*, and $r(x)$ is a polynomial of degree $l < m$ or $r(x) = 0$, referred to as the *remainder*.

If $r(x) = 0$, then $f(x)$ is said to be *divisible* by $p(x)$ (without remainder).

If $m > n$, then $q(x) = 0$ and $r(x) \equiv f(x)$.

► Methods for finding quotient and remainder.

1°. *Horner's scheme*. To divide a polynomial $f(x)$ of degree n (see (M5.1.1.1)) by the polynomial $p(x) = x - b$, one uses Horner's scheme: the coefficients of $f(x)$ are written out in a row, starting from a_n; b is written on the left; then one writes the number a_n under a_n, the number $a_n b + a_{n-1} = b_{n-1}$ under a_{n-1}, the number $b_{n-1}b + a_{n-2} = b_{n-2}$ under $a_{n-2}, \dots,$ the number $b_1 b + a_0 = b_0$ under a_0. The number b_0 is the remainder in the division of $f(x)$ by $p(x)$, and $a_n, b_{n-1}, \dots, b_1$ are the coefficients of the quotient.

Remark. To divide $f(x)$ by $p(x) = ax + b$ ($a \neq 0$) with remainder, one first uses Horner's scheme to divide by $p_1(x) = x - (-\frac{b}{a})$; now if $q_1(x)$ and r_1 are the quotient and remainder in the division of $f(x)$ by $p_1(x)$, then $q(x) = \frac{1}{a} q_1(x)$ and $r = r_1$ are the quotient and remainder in the division of $f(x)$ by $p(x)$.

Example 1. Let us divide $f(x) = x^3 - 2x^2 - 10x + 3$ by $p(x) = 2x + 5$.
We use Horner's scheme to divide $f(x)$ by $p_1(x) = x + 5/2$:

$$\begin{array}{c|cccc} & 1 & -2 & -10 & 3 \\ \hline -\frac{5}{2} & 1 & -\frac{9}{2} & \frac{5}{4} & -\frac{1}{8} \end{array}$$

Thus $f(x) = p(x)q(x) + r(x)$, where

$$q(x) = \frac{1}{2}\Big(x^2 - \frac{9}{2}x + \frac{5}{4}\Big) = \frac{1}{2}x^2 - \frac{9}{4}x + \frac{5}{8}, \quad r = -\frac{1}{8}.$$

POLYNOMIAL REMAINDER THEOREM. *The remainder in the division of a polynomial $f(x)$ by the polynomial $p(x) = x - b$ is the number equal to the value of the polynomial $f(x)$ at $x = b$.*

2°. *Long division.* To divide a polynomial $f(x)$ of degree n by a polynomial $p(x)$ of degree $m \le n$, one can use *long division*.

Example 2. Let us divide $f(x) = x^3 + 8x^2 + 14x - 5$ by $p(x) = x^2 + 3x - 1$.
We use long division:

$$\begin{array}{rr|l} - & x^3 + 8x^2 + 14x - 5 & x^2 + 3x - 1 \\ \cline{3-3} & x^3 + 3x^2 \quad\;\; - x & x + 5 \\ \cline{2-2} - & 5x^2 + 15x - 5 & \\ & 5x^2 + 15x - 5 & \\ \cline{2-2} & 0 & \end{array}$$

Thus $f(x) = p(x)q(x) + r(x)$, where $q(x) = x + 5$ and $r(x) = 0$; i.e., $f(x)$ is divisible by $p(x)$.

Example 3. Let us divide $f(x) = x^3 - 4x^2 + x + 1$ by $p(x) = x^2 + 1$.
We use long division:

$$\begin{array}{rr|l} - & x^3 - 4x^2 + x + 1 & x^2 + 1 \\ \cline{3-3} & x^3 \qquad\;\; + x \quad\; & x - 4 \\ \cline{2-2} - & -4x^2 \qquad + 1 & \\ & -4x^2 \qquad - 4 & \\ \cline{2-2} & 5 & \end{array}$$

Thus $f(x) = p(x)q(x) + r(x)$, where $q(x) = x - 4$ and $r(x) = 5$.

► Expansion of polynomials in powers of a linear binomial. For each polynomial $f(x)$ given by equation (M5.1.1.1) and any number c, one can write out the *expansion of $f(x)$ in powers of $x - c$*:

$$f(x) = b_n(x - c)^n + b_{n-1}(x - c)^{n-1} + \cdots + b_1(x - c) + b_0.$$

To find the coefficients $b_0, \dots, b_n$ of this expansion, one first divides $f(x)$ by $x - c$ with remainder. The remainder is b_0, and the quotient is some polynomial $g_0(x)$. Then one divides

$g_0(x)$ by $x-c$ with remainder. The remainder is b_1, and the quotient is some polynomial $g_1(x)$. Then one divides $g_1(x)$ by $x-c$, obtaining the coefficient b_2 as the remainder, etc. It is convenient to perform the computations by Horner's scheme (see above).

The coefficients in the expansion of a polynomial $f(x)$ in powers of the difference $x-c$ are related to the values of the polynomial and its derivatives at $x=c$ by the formulas

$$b_0 = f(c), \quad b_1 = \frac{f'_x(c)}{1!}, \quad b_2 = \frac{f''_{xx}(c)}{2!}, \quad \ldots, \quad b_n = \frac{f^{(n)}_x(c)}{n!},$$

where the *derivative of a polynomial* $f(x) = a_n x^n + a_{n-1}x^{n-1} + \cdots + a_1 x + x_0$ with real or complex coefficients $a_0, \ldots, a_n$ is the polynomial $f'_x(x) = na_n x^{n-1} + (n-1)a_{n-1}x^{n-2} + \cdots + a_1$, $f''_{xx}(x) = [f'_x(x)]'_x$, etc. (see Subsection M6.2.1).

M5.1.2. Linear and Quadratic Equations

► **Linear equations.** The linear equation

$$ax + b = 0 \quad (a \neq 0)$$

has the solution

$$x = -\frac{b}{a}.$$

► **Quadratic equations.** The quadratic equation

$$ax^2 + bx + c = 0 \quad (a \neq 0) \tag{M5.1.2.1}$$

has the roots

$$x_{1,2} = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}.$$

The existence of real or complex roots is determined by the sign of the discriminant $D = b^2 - 4ac$:

Case $D > 0$. There are two distinct real roots.

Case $D < 0$. There are two distinct complex conjugate roots.

Case $D = 0$. There are two equal real roots.

VIÈTE THEOREM. *The roots of a quadratic equation (M5.1.2.1) satisfy the following relations:*

$$x_1 + x_2 = -\frac{b}{a}, \qquad x_1 x_2 = \frac{c}{a}.$$

M5.1.3. Cubic Equations

► **Incomplete cubic equation.**

1°. *Cardano's solution.* The roots of the incomplete cubic equation

$$y^3 + py + q = 0 \tag{M5.1.3.1}$$

have the form

$$y_1 = A + B, \quad y_{2,3} = -\frac{1}{2}(A+B) \pm i\frac{\sqrt{3}}{2}(A-B),$$

where

$$A=\left(-\frac{q}{2}+\sqrt{D}\right)^{1/3},\quad B=\left(-\frac{q}{2}-\sqrt{D}\right)^{1/3},\quad D=\left(\frac{p}{3}\right)^3+\left(\frac{q}{2}\right)^2,\quad i^2=-1,$$

and A, B are arbitrary values of the cubic roots such that $AB=-\frac{1}{3}p$.

The number of real roots of a cubic equation depends on the sign of the discriminant D:

Case $D>0$. There is one real and two complex conjugate roots.

Case $D<0$. There are three real roots.

Case $D=0$. There is one real root and another real root of double multiplicity.

2°. *Trigonometric solution.* If an incomplete cubic equation (M5.1.3.1) has real coefficients p and q, then its solutions can be found with the help of the trigonometric formulas given below.

(*a*) Let $p<0$ and $D<0$. Then

$$y_1=2\sqrt{-\frac{p}{3}}\cos\frac{\alpha}{3},\quad y_{2,3}=-2\sqrt{-\frac{p}{3}}\cos\left(\frac{\alpha}{3}\pm\frac{\pi}{3}\right),$$

where the values of the trigonometric functions are calculated from the relation

$$\cos\alpha=-\frac{q}{2\sqrt{-(p/3)^3}}.$$

(*b*) Let $p>0$ and $D\ge 0$. Then

$$y_1=2\sqrt{\frac{p}{3}}\cot(2\alpha),\quad y_{2,3}=\sqrt{\frac{p}{3}}\left[\cot(2\alpha)\pm i\frac{\sqrt{3}}{\sin(2\alpha)}\right],$$

where the values of the trigonometric functions are calculated from the relations

$$\tan\alpha=\left(\tan\frac{\beta}{2}\right)^{1/3},\quad \tan\beta=\frac{2}{q}\left(\frac{p}{3}\right)^{3/2},\quad |\alpha|\le\frac{\pi}{4},\quad |\beta|\le\frac{\pi}{2}.$$

(*c*) Let $p<0$ and $D\ge 0$. Then

$$y_1=-2\sqrt{-\frac{p}{3}}\frac{1}{\sin(2\alpha)},\quad y_{2,3}=\sqrt{-\frac{p}{3}}\left[\frac{1}{\sin(2\alpha)}\pm i\sqrt{3}\cot(2\alpha)\right],$$

where the values of the trigonometric functions are calculated from the relations

$$\tan\alpha=\left(\tan\frac{\beta}{2}\right)^{1/3},\quad \sin\beta=\frac{2}{q}\left(-\frac{p}{3}\right)^{3/2},\quad |\alpha|\le\frac{\pi}{4},\quad |\beta|\le\frac{\pi}{2}.$$

In the above three cases, the real value of the cubic root should be taken.

► **Complete cubic equation**. The roots of a complete cubic equation

$$ax^3+bx^2+cx+d=0\quad (a\neq 0)\qquad\text{(M5.1.3.2)}$$

are calculated by the formulas

$$x_k=y_k-\frac{b}{3a},\quad k=1,\,2,\,3,$$

where y_k are the roots of the incomplete cubic equation (M5.1.3.1) with the coefficients

$$p=-\frac{1}{3}\left(\frac{b}{a}\right)^2+\frac{c}{a},\quad q=\frac{2}{27}\left(\frac{b}{a}\right)^3-\frac{bc}{3a^2}+\frac{d}{a}.$$

VIÈTE THEOREM. *The roots of a complete cubic equation (M5.1.3.2) satisfy the following relations:*

$$x_1+x_2+x_3=-\frac{b}{a},\quad x_1x_2+x_1x_3+x_2x_3=\frac{c}{a},\quad x_1x_2x_3=-\frac{d}{a}.$$

M5.1.4. Fourth-Degree Equation

► Special cases of fourth-degree equations.

1°. The *biquadratic equation*

$$ax^4 + bx^2 + c = 0$$

can be reduced to a quadratic equation (M5.1.2.1) by the substitution $\xi = x^2$. Therefore, the roots of the biquadratic equations are given by

$$x_{1,2} = \pm\sqrt{\frac{-b + \sqrt{b^2 - 4ac}}{2a}}, \quad x_{3,4} = \pm\sqrt{\frac{-b - \sqrt{b^2 - 4ac}}{2a}}.$$

2°. The *reciprocal (algebraic) equation*

$$ax^4 + bx^3 + cx^2 + bx + a = 0$$

can be reduced to a quadratic equation by the substitution

$$y = x + \frac{1}{x}.$$

The resulting quadratic equation has the form

$$ay^2 + by + c - 2a = 0.$$

3°. The *generalized reciprocal equation*

$$ax^4 + bx^3 + cx^2 + \lambda bx + \lambda^2 a = 0$$

can be reduced to a quadratic equation by the substitution

$$y = x + \frac{\lambda}{x}.$$

The resulting quadratic equation has the form

$$ay^2 + by + c - 2a\lambda = 0.$$

► General fourth-degree equation.

1°. *Reduction of a general fourth-degree equation to an incomplete equation.* The general fourth-degree equation

$$ax^4 + bx^3 + cx^2 + dx + e = 0 \quad (a \neq 0)$$

can be reduced to an incomplete equation of the form

$$y^4 + py^2 + qy + r = 0 \qquad \text{(M5.1.4.1)}$$

by the substitution

$$x = y - \frac{b}{4a}.$$

2°. *Descartes–Euler solution.* The roots of the incomplete equation (M5.1.4.1) are given by the formulas

$$\begin{aligned} y_1 &= \tfrac{1}{2}\left(\sqrt{z_1} + \sqrt{z_2} + \sqrt{z_3}\right), & y_2 &= \tfrac{1}{2}\left(\sqrt{z_1} - \sqrt{z_2} - \sqrt{z_3}\right), \\ y_3 &= \tfrac{1}{2}\left(-\sqrt{z_1} + \sqrt{z_2} - \sqrt{z_3}\right), & y_4 &= \tfrac{1}{2}\left(-\sqrt{z_1} - \sqrt{z_2} + \sqrt{z_3}\right), \end{aligned} \qquad \text{(M5.1.4.2)}$$

where z_1, z_2, z_3 are the roots of the cubic equation (cubic resolvent of equation (M5.1.4.1))

$$z^3 + 2pz^2 + (p^2 - 4r)z - q^2 = 0. \qquad \text{(M5.1.4.3)}$$

The signs of the roots in (M5.1.4.2) are chosen from the condition

$$\sqrt{z_1}\sqrt{z_2}\sqrt{z_3} = -q.$$

The roots of the fourth-degree equation (M5.1.4.1) are determined by the roots of the cubic resolvent (M5.1.4.3); see Table M5.1.

TABLE M5.1
Relations between the roots of an incomplete equation of fourth-degree and the roots of its cubic resolvent.

Cubic resolvent (M5.1.4.3)	Fourth-degree equation (M5.1.4.1)
All roots are real and positive*	Four real roots
All roots are real: one is positive and two are negative*	Two pairs of complex conjugate roots
One real root and two complex conjugate roots	Two real roots and two complex conjugate roots

* By the Viète theorem, the product of the roots z_1, z_2, z_3 is equal to $q^2 \geq 0$.

3°. *Ferrari solution.* Let z_0 be any of the roots of the auxiliary cubic equation (M5.1.4.3). Then the four roots of the incomplete equation (M5.1.4.1) are found by solving the following two quadratic equations:

$$y^2 - \sqrt{z_0}\,y + \frac{p+z_0}{2} + \frac{q}{2\sqrt{z_0}} = 0,$$
$$y^2 + \sqrt{z_0}\,y + \frac{p+z_0}{2} - \frac{q}{2\sqrt{z_0}} = 0.$$

M5.1.5. Algebraic Equations of Arbitrary Degree and Their Properties

► **Simplest equations of degree n and their solutions.**

1°. The *binomial algebraic equation*

$$x^n - a = 0 \quad (a \neq 0)$$

has the solutions

$$x_{k+1} = \begin{cases} a^{1/n}\left(\cos\dfrac{2k\pi}{n} + i\sin\dfrac{2k\pi}{n}\right) & \text{for } a > 0, \\ |a|^{1/n}\left(\cos\dfrac{(2k+1)\pi}{n} + i\sin\dfrac{(2k+1)\pi}{n}\right) & \text{for } a < 0, \end{cases}$$

where $k = 0, 1, \ldots, n-1$ and $i^2 = -1$.

2°. Equations of the form

$$x^{2n} + ax^n + b = 0,$$
$$x^{3n} + ax^{2n} + bx^n + c = 0,$$
$$x^{4n} + ax^{3n} + bx^{2n} + cx^n + d = 0$$

are reduced by the substitution $y = x^n$ to a quadratic, cubic, and fourth-degree equation, respectively, whose solution can be expressed by radicals (see Subsections M5.1.2–M5.1.4).

Remark. In the above equations, n can be noninteger.

3°. The *generalized reciprocal (algebraic) equation*

$$a_0x^{2n}+a_1x^{2n-1}+\cdots+a_{n-1}x^{n+1}+a_nx^n + \lambda a_{n-1}x^{n-1}+\lambda^2a_{n-2}x^{n-2}+\cdots+\lambda^{n-1}a_1x+\lambda^na_0=0 \qquad (a_0\neq 0).$$

can be reduced to an equation of degree n by the substitution

$$y=x+\frac{\lambda}{x}.$$

Example 1. The equation

$$ax^6+bx^5+cx^4+dx^3+cx^2+bx+a=0,$$

which is a special case of the reciprocal equation with $n=3$ and $\lambda=1$, can be reduced to the cubic equation

$$ay^3+by^2+(c-3a)y+d-2b=0$$

by the substitution $y=x+1/x$.

► **Equations of general form and their properties.** An *algebraic equation of degree* n has the form

$$a_nx^n+a_{n-1}x^{n-1}+\cdots+a_1x+a_0=0 \quad (a_n\neq 0), \tag{M5.1.5.1}$$

where a_k are real or complex coefficients. Denote the polynomial of degree n on the left-hand side in equation (M5.1.5.1) by

$$P_n(x)\equiv a_nx^n+a_{n-1}x^{n-1}+\cdots+a_1x+a_0 \quad (a_n\neq 0). \tag{M5.1.5.2}$$

A value $x=x_1$ such that $P_n(x_1)=0$ is called a *root* of equation (M5.1.5.1) (and also a root of the polynomial $P_n(x)$). A value $x=x_1$ is called a *root of multiplicity* m if $P_n(x)=(x-x_1)^mQ_{n-m}(x)$, where m is an integer $(1\leq m\leq n)$, and $Q_{n-m}(x)$ is a polynomial of degree $n-m$ such that $Q_{n-m}(x_1)\neq 0$.

THEOREM 1 (FUNDAMENTAL THEOREM OF ALGEBRA). *Any algebraic equation of degree n has exactly n roots (real or complex), each root counted according to its multiplicity.*

Thus, the left-hand side of equation (M5.1.5.1) with roots $x_1, x_2, \ldots, x_s$ of the respective multiplicities $k_1, k_2, \ldots, k_s$ $(k_1+k_2+\cdots+k_s=n)$ can be factorized as follows:

$$P_n(x)=a_n(x-x_1)^{k_1}(x-x_2)^{k_2}\ldots(x-x_s)^{k_s}.$$

THEOREM 2. *Any algebraic equation of an odd degree with real coefficients has at least one real root.*

THEOREM 3. *Suppose that equation (M5.1.5.1) with real coefficients has a complex root $x_1=\alpha+i\beta$. Then this equation has the complex conjugate root $x_2=\alpha-i\beta$, and the roots x_1, x_2 have the same multiplicity.*

THEOREM 4. *Any rational root of equation (M5.1.5.1) with integer coefficients a_k is an irreducible fraction of the form p/q, where p is a divisor of a_0 and q is a divisor of a_n. If $a_n=1$, then all rational roots of equation (M5.1.5.1) (if they exist) are integer divisors of the free term.*

THEOREM 5 (ABEL–RUFFINI THEOREM). *Any equation (M5.1.5.1) of degree $n\leq 4$ is solvable by radicals, i.e., its roots can be expressed via its coefficients by the operations of addition, subtraction, multiplication, division, and taking roots (see Subsections M5.1.2–M5.1.4). In general, equation (M5.1.5.1) of degree $n>4$ cannot be solved by radicals.*

► Relations between roots and coefficients. Discriminant of an equation.

VIÈTE THEOREM. *The roots of equation (M5.1.5.1) (counted according to their multiplicity) and its coefficients satisfy the following relations:*

$$(-1)^k \frac{a_{n-k}}{a_n} = S_k \quad (k = 1,\,2,\,\ldots,\,n),$$

where S_k are elementary symmetric functions of $x_1, x_2, \ldots, x_n$:

$$S_1 = \sum_{i=1}^{n} x_i, \quad S_2 = \sum_{1\le i<j}^{n} x_i x_j, \quad S_3 = \sum_{1\le i<j<k}^{n} x_i x_j x_k, \quad \ldots, \quad S_n = x_1 x_2 \ldots x_n.$$

Note also the following relations:

$$(n-k)a_{n-k} + \sum_{j=1}^{k} a_{n-(k-j)} s_j = 0 \quad (k = 1,\,2,\,\ldots,\,n)$$

with symmetric functions $s_j = \sum\limits_{i=1}^{n} x_i^j$.

The *discriminant D of an algebraic equation* is the product of a_n^{2n-2} and the squared Vandermonde determinant $\Delta(x_1, x_2, \ldots, x_n)$ of its roots:

$$D = a_n^{2n-2}[\Delta(x_1, x_2, \ldots, x_n)]^2 = a_n^{2n-2} \prod_{1\le j<i\le n} (x_i - x_j)^2.$$

The discriminant D is a symmetric function of the roots $x_1, x_2, \ldots, x_n$, and is equal to zero if and only if the polynomial $P_n(x)$ has at least one multiple root.

► Bounds for the roots of algebraic equations with real coefficients.

1°. All roots of equation (M5.1.5.1) in absolute value do not exceed

$$N = 1 + \frac{A}{|a_n|}, \qquad \text{(M5.1.5.3)}$$

where A is the largest of $|a_0|, |a_1|, \ldots, |a_{n-1}|$.

The last result admits the following generalization: all roots of equation (M5.1.5.1) in absolute value do not exceed

$$N_1 = \rho + \frac{A_1}{|a_n|}, \qquad \text{(M5.1.5.4)}$$

where $\rho > 0$ is arbitrary and A_1 is the largest of

$$|a_{n-1}|, \quad \frac{|a_{n-2}|}{\rho}, \quad \frac{|a_{n-3}|}{\rho^2}, \quad \ldots, \quad \frac{|a_0|}{\rho^{n-1}}.$$

For $\rho = 1$, formula (M5.1.5.4) turns into (M5.1.5.3).

Remark. Formulas (M5.1.5.3) and (M5.1.5.4) can also be used for equations with complex coefficients.

Example 2. Consider the following equation of degree 4:

$$P_4(x) = 9x^4 - 9x^2 - 36x + 1.$$

Formula (M5.1.5.3) for $n = 4$, $|a_n| = 9$, $A = 36$ yields a fairly rough estimate $N = 5$, i.e., the roots of the equation belong to the interval $[-5, 5]$. Formula (M5.1.5.4) for $\rho = 2$, $n = 4$, $|a_n| = 9$, $A_1 = 9$ yields a better estimate for the bounds of the roots of this polynomial, $N_1 = 3$.

2°. A constant K is called an upper bound for the real roots of equation (M5.1.5.1) or the polynomial $P_n(x)$ if equation (M5.1.5.1) has no real roots greater than or equal to K; in a similar way, one defines a lower and an upper bound for positive and negative roots of an equation or the corresponding polynomial.

Let

K_1 be an upper bound for the positive roots of the polynomial $P_n(x)$,

K_2 be an upper bound for the positive roots of the polynomial $P_n(-x)$,

$K_3 > 0$ be an upper bound for the positive roots of the polynomial $x^n P_n(1/x)$,

$K_4 > 0$ be an upper bound for the positive roots of the polynomial $x^n P_n(-1/x)$.

Then all nonzero real roots of the polynomial $P_n(x)$ (if they exist) belong to the intervals $(-K_2, -1/K_4)$ and $(1/K_3, K_1)$.

Next, we describe three methods for finding upper bounds for positive roots of a polynomial.

Maclaurin method. Suppose that the first m leading coefficients of the polynomial (M5.1.5.2) are nonnegative, i.e., $a_n > 0$, $a_{n-1} \geq 0$, …, $a_{n-m+1} \geq 0$, and the next coefficient is negative, $a_{n-m} < 0$. Then

$$K = 1 + \left(\frac{B}{a_n}\right)^{1/m} \tag{M5.1.5.5}$$

is an upper bound for the positive roots of this polynomial, where B is the largest of the absolute values of negative coefficients of $P_n(x)$.

Example 3. Consider the fourth-degree equation from Example 2. In this case, $m = 2$, $B = 36$ and formula (M5.1.5.5) yields $K = K_1 = 1 + (36/9)^{1/2} = 3$. Now, consider the polynomial $P_4(-x) = 9x^4 - 9x^2 + 36x + 1$. Its positive roots has the upper bound $K_2 = 1 + (9/9)^{1/2} = 2$. For the polynomial $x^4 P_4(1/x) = x^4 - 36x^3 - 9x^2 + 9$, we have $m = 1$, $K_3 = 1 + 36 = 37$. Finally, for the polynomial $x^4 P_4(-1/x) = x^4 + 36x^3 - 9x^2 + 9$, we have $m = 2$, $k_4 = 1 + 9^{1/2} = 4$. Thus if $P_4(x)$ has real roots, they must belong to the intervals $(-2, -1/4)$ and $(1/37, 3)$.

Newton method. Suppose that the polynomial $P_n(x)$ and all its derivatives $P_n'(x)$, …, $P_n^{(n)}(x)$ take positive values for $x = c$. Then c is an upper bound for the positive roots of $P_n(x)$.

Example 4. Consider the polynomial from Example 2 and calculate the derivatives

$$P_4(x) = 9x^4 - 9x^2 - 36x + 1,\quad P_4'(x) = 36x^3 - 18x - 36,\quad P_4''(x) = 108x^2 - 18,\quad P_4'''(x) = 216x,\quad P_4''''(x) = 216.$$

It is easy to check that for $x = 2$ this polynomial and all its derivatives take positive values, and therefore $c = 2$ is an upper bound for its positive roots.

► **Theorems on the number of real roots of polynomials.** The number of all negative roots of a polynomial $P_n(x)$ is equal to the number of all positive roots of the polynomial $P_n(-x)$.

1°. The exact number of positive roots of a polynomial whose coefficients form a sequence that does not change sign or changes sign only once can be found with the help of the Descartes theorem (rule of signs).

DESCARTES THEOREM. *The number of positive roots (counted considering their multiplicity) of a polynomial $P_n(x)$ with real coefficients is either equal to the number of sign alterations between consecutive nonzero coefficients or is less than it by a multiple of 2.*

Applying the Descartes theorem to $P_n(-x)$, we obtain a similar theorem for the negative roots of the polynomial $P_n(x)$.

Example 5. Consider the cubic polynomial

$$P_3(x) = x^3 - 3x + a^2 \quad (a \neq 0).$$

Its coefficients have the signs + – +, and therefore we have two alterations of sign. Therefore, the number of positive roots of $P_3(x)$ is equal either to 2 or to 0. Now, consider the polynomial $P_3(-x) = -x^3 + 3x + a^2$. The sequence of its coefficients changes sign only once. Therefore, the original equation has one negative root.

2°. *A stronger version of the Descartes theorem.* Suppose that all roots of a polynomial $P_n(x)$ are real*; then the number of positive roots of $P_n(x)$ is equal to the number of sign alterations in the sequence of its coefficients, and the number of its negative roots is equal to the number of sign alterations in the sequence of coefficients of the polynomial $P_n(-x)$.

Example 6. Consider the characteristic polynomial of the symmetric matrix

$$P_3(x) = \begin{vmatrix} -2-x & 1 & 1 \\ 1 & 1-x & 3 \\ 1 & 3 & 1-x \end{vmatrix} = -x^3 + 14x + 20,$$

which has only real roots. The sequence of its coefficients changes sign only once, and therefore it has a single positive root. The number of its negative roots is equal to two, since this polynomial has three nonzero real roots and only one of them can be positive.

3°. If two neighboring coefficients of a polynomial $P_n(x)$ are equal to zero, then the roots of the polynomial cannot be all real (in this case, the stronger version of the Descartes theorem cannot be used).

4°. The number of real roots of a polynomial $P_n(x)$ greater than a fixed c is either equal to the number of sign alterations in the sequence $P_n(c), \dots, P_n^{(n)}(c)$ or is by an even number less. If all roots of $P_n(x)$ are real, then the number of its roots greater than c coincides with the number of sign alterations in the sequence $P_n(c), \dots, P_n^{(n)}(c)$.

Example 7. Consider the polynomial

$$P_4(x) = x^4 - 3x^3 + 2x^2 - 2a^2 x + a^2.$$

For $x = 1$, we have $P_4(1) = -a^2$, $P_4'(1) = -1 - 2a^2$, $P_4''(1) = -2$, $P_4'''(1) = 6$, $P_4''''(1) = 24$. Thus, there is a single sign alteration, and therefore the polynomial has a single real root greater than unity.

M5.2. Determinants and Matrices

M5.2.1. Determinants

► Second-order, third-order, and nth-order determinants.

1°. The *second-order determinant* is a number Δ associated with 4 scalar quantities a_{11}, a_{12}, a_{21}, a_{22}, arranged in a 2×2 square table. It is denoted and calculated as

$$\Delta = \begin{vmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{vmatrix} = a_{11}a_{22} - a_{12}a_{21}.$$

The numbers a_{11}, a_{12}, a_{21}, and a_{22} are called elements of the determinant Δ.

2°. The *third-order determinant* is a number Δ associated with a 3×3 square table of 9 scalar quantities; it is denoted and calculated as

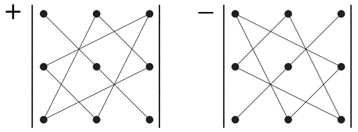
$$\Delta = \begin{vmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{vmatrix}$$

$$= a_{11}a_{22}a_{33} + a_{12}a_{23}a_{31} + a_{13}a_{21}a_{32} - a_{13}a_{22}a_{31} - a_{12}a_{21}a_{33} - a_{11}a_{23}a_{32}.$$

---

* This is the case, for instance, if we are dealing with the characteristic polynomial of a symmetric matrix.

This expression is obtained by the *triangle rule* (*Sarrus scheme*), illustrated by the following diagrams, where entries occurring in the same product with a given sign are joined by segments:



3°. The *nth-order determinant* is a number Δ associated with an $n\times n$ square table of n^2 scalar quantities; it is denoted by

$$\Delta = \begin{vmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{n1} & a_{n2} & \cdots & a_{nn} \end{vmatrix}. \qquad \text{(M5.2.1.1)}$$

The numbers a_{ij} are elements of the determinant Δ.

The determinant (M5.2.1.1) is calculated using the formulas

$$\begin{aligned} \Delta &= a_{i1}A_{i1} + a_{i2}A_{i2} + \cdots + a_{in}A_{in} \\ &= a_{1j}A_{1j} + a_{2j}A_{2j} + \cdots + a_{nj}A_{nj} \end{aligned} \qquad \text{(M5.2.1.2)}$$

for any ith row and jth column. Here, A_{ij} is the *cofactor* of the element a_{ij}, which is defined as $A_{ij} = (-1)^{i+j}M_{ij}$, where M_{ij} is the *minor* corresponding to a_{ij}. The minor M_{ij} is defined as the $(n-1)$st-order determinant of size $(n-1)\times(n-1)$ obtained from the original determinant by removing the ith row and the jth column (i.e., the row and the column that intersect at a_{ij}). It follows from (M5.2.1.2) that the calculation of an nth-order determinant is reduced to the calculation of n determinants of order $n-1$.

The first formula in (M5.2.1.2) is called the *cofactor expansion of the determinant along row i* and the other one is called the *cofactor expansion of the determinant along column j*.

► Properties of determinants.

1. If a determinant contains a row (column) consisting of all zeroes, then this determinant is equal to zero.
2. If a determinant has two proportional rows (columns), then the determinant is zero.
3. If a determinant has a row (column) that is a linear combination of its other rows (columns), then the determinant is zero.
4. If two rows (columns) are interchanged, the determinant changes its sign.
5. If each element of a row (column) is divisible by a common number, this number can be factored out of the determinant.
6. The determinant does not change if a linear combination of some of its rows (columns) is added to another row (column).

Remark. The determinant is equal to zero if and only if its rows (columns) are linearly dependent.

► Calculation of determinants.

1°. Determinants can be calculated using the above properties.

Example 1. Find the determinant

$$\Delta = \begin{vmatrix} -13 & 25 & 17 \\ 26 & -34 & -26 \\ 36 & -33 & -24 \end{vmatrix}.$$

We first factor out the common divisor 2 of the elements in the second row, then add the resulting second row to the first one and then add the second row multiplied by –2 to the third one to obtain

$$\Delta = 2\begin{vmatrix} -13 & 25 & 17 \\ 13 & -17 & -13 \\ 36 & -33 & -24 \end{vmatrix} = 2\begin{vmatrix} 0 & 8 & 4 \\ 13 & -17 & -13 \\ 10 & 1 & 2 \end{vmatrix}.$$

In the last determinant, by adding the third column multiplied by –2 to the second one and by using the cofactor expansion along the first row, one obtains

$$\Delta = 2\begin{vmatrix} 0 & 0 & 4 \\ 13 & 9 & -13 \\ 10 & -3 & 2 \end{vmatrix} = 2\times 4\begin{vmatrix} 13 & 9 \\ 10 & -3 \end{vmatrix} = 8\,(-39-90) = -1032.$$

2°. Determinants are often calculated using the cofactor expansion formulas (M5.2.1.2). To this end, its is convenient to take a row or a column that contains many zero elements.

Example 2. Find the third-order determinant

$$A = \begin{vmatrix} 1 & -1 & 2 \\ 6 & 1 & 5 \\ 2 & -1 & -4 \end{vmatrix}.$$

We perform the cofactor expansion along the second column:

$$\det A = \sum_{k=1}^{3}(-1)^{k+2}a_{k2}M_{k2} = (-1)^{1+2}\times(-1)\times\begin{vmatrix} 6 & 5 \\ 2 & -4 \end{vmatrix} + (-1)^{2+2}\times 1\times\begin{vmatrix} 1 & 2 \\ 2 & -4 \end{vmatrix} + (-1)^{3+2}\times(-1)\times\begin{vmatrix} 1 & 2 \\ 6 & 5 \end{vmatrix}$$

$$= 1\times[6\times(-4)-5\times 2] + 1\times[1\times(-4)-2\times 2] + 1\times[1\times 5-2\times 6] = -49.$$

M5.2.2. Matrices. Types of Matrices. Operations with Matrices

► **Definition of a matrix. Types of matrices.** A *matrix* of *size* (or *dimension*) $m\times n$ is a rectangular table with *entries* a_{ij} ($i = 1, 2, \dots, m$; $j = 1, 2, \dots, n$) arranged in m rows and n columns:

$$A \equiv \begin{pmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{m1} & a_{m2} & \cdots & a_{mn} \end{pmatrix}. \qquad \text{(M5.2.2.1)}$$

Note that, for each entry a_{ij}, the index i refers to the ith row and the index j to the jth column. Matrices are briefly denoted by uppercase letters (for instance, A, as here), or by the symbol $[a_{ij}]$, sometimes with more details: $A \equiv [a_{ij}]$ ($i = 1, 2, \dots, m$; $j = 1, 2, \dots, n$). The numbers m and n are called the *dimensions* of the matrix.

The *null* or *zero matrix* is a matrix whose entries are all equal to zero: $a_{ij} = 0$ ($i = 1, 2, \dots, m$, $j = 1, 2, \dots, n$).

A *column vector* or *column* is a matrix of size $m\times 1$. A *row vector* or *row* is a matrix of size $1\times n$. Both column and row vectors are often simply called *vectors*.

A *square matrix* is a matrix of size $n\times n$, and n is called the dimension of this square matrix. The *main diagonal* of a square matrix is its diagonal from the top left corner to the bottom right corner with the entries $a_{11}\ a_{22}\ \dots\ a_{nn}$. Table M5.2 lists the main types of square matrices.

► **Basic operations with matrices.** Two matrices are *equal* if they are of the same size and their respective entries are equal.

The *sum* of two matrices $A \equiv [a_{ij}]$ and $B \equiv [b_{ij}]$ of the same size $m\times n$ is the matrix $C \equiv [c_{ij}]$ of size $m\times n$ with the entries

$$c_{ij} = a_{ij} + b_{ij}.$$

TABLE M5.2
Some types of square matrices.

Type of square matrix $[a_{ij}]$	Entries
Unit (identity) $I = [\delta_{ij}]$	$a_{ij} = \delta_{ij} = \begin{cases} 1, & i = j, \\ 0, & i \neq j \end{cases}$ (δ_{ij} is the Kronecker delta)
Diagonal	$a_{ij} = \begin{cases} \text{any}, & i = j, \\ 0, & i \neq j \end{cases}$
Upper triangular (superdiagonal)	$a_{ij} = \begin{cases} \text{any}, & i \le j, \\ 0, & i > j \end{cases}$
Lower triangular (subdiagonal)	$a_{ij} = \begin{cases} \text{any}, & i \ge j, \\ 0, & i < j \end{cases}$
Symmetric	$a_{ij} = a_{ji}$
Skew-symmetric (antisymmetric)	$a_{ij} = -a_{ji}$
Hermitian (self-adjoint)	$a_{ij} = \bar{a}_{ji}$ ($\bar{a}_{ji}$ is the complex conjugate of a number a_{ji})

The sum of two matrices is denoted by $C = A + B$, and the operation is called *addition of matrices*.

Properties of addition of matrices:

$$\begin{aligned} &A + O = A && \text{(property of zero matrix)}, \\ &A + B = B + A && \text{(commutativity)}, \\ &(A + B) + C = A + (B + C) && \text{(associativity)}, \end{aligned}$$

where matrices A, B, C, and zero matrix O have the same size.

The *difference* of two matrices $A \equiv [a_{ij}]$ and $B \equiv [b_{ij}]$ of the same size $m \times n$ is the matrix $C \equiv [c_{ij}]$ of size $m \times n$ with entries

$$c_{ij} = a_{ij} - b_{ij} \quad (i = 1,\ 2,\ \ldots,\ m;\ j = 1,\ 2,\ \ldots,\ n).$$

The difference of two matrices is denoted by $C = A - B$, and the operation is called *subtraction of matrices*.

The *product* of a matrix $A \equiv [a_{ij}]$ of size $m \times n$ by a scalar λ is the matrix $C \equiv [c_{ij}]$ of size $m \times n$ with entries

$$c_{ij} = \lambda a_{ij} \quad (i = 1,\ 2,\ \ldots,\ m;\ j = 1,\ 2,\ \ldots,\ n).$$

The product of a matrix by a scalar is denoted by $C = \lambda A$, and the operation is called *multiplication of a matrix by a scalar*.

Properties of multiplication of a matrix by a scalar:

$$\begin{aligned} &0A = O && \text{(property of zero)}, \\ &(\lambda\mu)A = \lambda(\mu A) && \text{(associativity with respect to a scalar factor)}, \\ &\lambda(A + B) = \lambda A + \lambda B && \text{(distributivity with respect to addition of matrices)}, \\ &(\lambda + \mu)A = \lambda A + \mu A && \text{(distributivity with respect to addition of scalars)}, \end{aligned}$$

where λ and μ are scalars, matrices A, B, C, and zero matrix O have the same size.

The *product* of a matrix $A \equiv [a_{ij}]$ of size $m \times p$ and a matrix $B \equiv [b_{ij}]$ of size $p \times n$ is the matrix $C \equiv [c_{ij}]$ of size $m \times n$ with entries

$$c_{ij} = \sum_{k=1}^{p} a_{ik} b_{kj} \quad (i = 1,\, 2,\, \ldots,\, m;\; j = 1,\, 2,\, \ldots,\, n);$$

i.e., the entry c_{ij} in the ith row and jth column of the matrix C is equal to the sum of products of the respective entries in the ith row of A and the jth column of B. Note that the product is defined for matrices of *compatible size*; i.e., the number of columns in the first matrix should be equal to the number of rows in the second matrix. The product of two matrices A and B is denoted by $C = AB$, and the operation is called *multiplication of matrices*.

Example 1. Consider two matrices

$$A = \begin{pmatrix} 1 & 2 \\ 6 & -3 \end{pmatrix} \quad \text{and} \quad B = \begin{pmatrix} 0 & 10 & 1 \\ -6 & -0.5 & 20 \end{pmatrix}.$$

The product of the matrix A and the matrix B is the matrix

$$\begin{aligned} C = AB &= \begin{pmatrix} 1 & 2 \\ 6 & -3 \end{pmatrix} \begin{pmatrix} 0 & 10 & 1 \\ -6 & -0.5 & 20 \end{pmatrix} \\ &= \begin{pmatrix} 1\times 0 + 2\times(-6) & 1\times 10 + 2\times(-0.5) & 1\times 1 + 2\times 20 \\ 6\times 0 + (-3)\times(-6) & 6\times 10 + (-3)\times(-0.5) & 6\times 1 + (-3)\times 20 \end{pmatrix} = \begin{pmatrix} -12 & 9 & 41 \\ 18 & 61.5 & -54 \end{pmatrix}. \end{aligned}$$

Properties of multiplication of matrices:

$$\begin{aligned} &AO = O_1 && \text{(property of zero matrix)},\\ &(AB)C = A(BC) && \text{(associativity of the product of three matrices)},\\ &AI = A && \text{(multiplication by unit matrix)},\\ &A(B + C) = AB + AC && \text{(distributivity with respect to a sum of two matrices)},\\ &\lambda(AB) = (\lambda A)B = A(\lambda B) && \text{(associativity of the product of a scalar and two matrices)},\\ &SD = DS && \text{(commutativity for any square and any diagonal matrices)}, \end{aligned}$$

where λ is a scalar, matrices A, B, C, square matrix S, diagonal matrix D, zero matrices O and O_1, and unit matrix I have the compatible sizes.

Two square matrices A and B are said to *commute* if $AB = BA$, i.e., if their multiplication is subject to the commutative law (in general, this is not the case).

► **Transpose, orthogonal, and adjoint matrix.** The *transpose* of a matrix $A \equiv [a_{ij}]$ of size $m \times n$ is the matrix $C \equiv [c_{ij}]$ of size $n \times m$ with entries

$$c_{ij} = a_{ji} \quad (i = 1,\, 2,\, \ldots,\, n;\; j = 1,\, 2,\, \ldots,\, m).$$

The transpose is denoted by $C = A^T$.

Example 2. If $A = (a_1, a_2)$ then $A^T = \begin{pmatrix} a_1 \\ a_2 \end{pmatrix}$.

Properties of transposes:

$$\begin{aligned} &(A + B)^T = A^T + B^T, \quad && (\lambda A)^T = \lambda A^T, \quad && (A^T)^T = A,\\ &(AC)^T = C^T A^T, && O^T = O_1, && I^T = I, \end{aligned}$$

where λ is a scalar; matrices A, B, and zero matrix O have size $m \times n$; matrix C has size $n \times l$; zero matrix O_1 has size $n \times m$.

THEOREM (DECOMPOSITION OF MATRICES). *For any square matrix A, the matrix $S_1 = \frac{1}{2}(A + A^T)$ is symmetric and the matrix $S_2 = \frac{1}{2}(A - A^T)$ is skew-symmetric. The representation of A as the sum of symmetric and skew-symmetric matrices is unique: $A = S_1 + S_2$.*

A square matrix A is said to be *orthogonal* if $A^T A = AA^T = I$, i.e., $A^T = A^{-1}$, where A^{-1} is the inverse of A (see Subsection M5.2.3).

Properties of orthogonal matrices:

1. If A is an orthogonal matrix, then A^T is also orthogonal.
2. The product of two orthogonal matrices is an orthogonal matrix.
3. Any symmetric orthogonal matrix is involutive, i.e., $AA = I$.

The *complex conjugate* of a matrix $A \equiv [a_{ij}]$ of size $m \times n$ is the matrix $C \equiv [c_{ij}]$ of size $m \times n$ with entries

$$c_{ij} = \bar{a}_{ij} \quad (i = 1, 2, \ldots, m;\ j = 1, 2, \ldots, n),$$

where $\bar{a}_{ij}$ is the complex conjugate of a_{ij}. The complex conjugate matrix is denoted by $C = \overline{A}$.

The *adjoint matrix* of a matrix $A \equiv [a_{ij}]$ of size $m \times n$ is the matrix $C \equiv [c_{ij}]$ of size $n \times m$ with entries

$$c_{ij} = \bar{a}_{ji} \quad (i = 1, 2, \ldots, n;\ j = 1, 2, \ldots, m).$$

The adjoint matrix is denoted by $C = A^*$.

Properties of adjoint matrices:

$$\begin{array}{lll} (A + B)^* = A^* + B^*, & (\lambda A)^* = \bar{\lambda} A^*, & (A^*)^* = A, \\ (AC)^* = C^* A^*, & O^* = O_1, & I^* = I, \end{array}$$

where λ is a scalar; matrices A, B, and zero matrix O have size $m \times n$; matrix C has size $n \times l$; zero matrix O_1 has size $n \times m$.

Remark. If a matrix is *real* (i.e., all its entries are real), then the corresponding transpose and the adjoint matrix coincide.

A square matrix A is said to be *normal* if $A^* A = AA^*$. A normal matrix A is said to be *unitary* if $A^* A = AA^* = I$, i.e., $A^* = A^{-1}$, where A^{-1} is the inverse of A (see Subsection M5.2.3).

► **Trace of a matrix.** The *trace* of a square matrix $A \equiv [a_{ij}]$ of size $n \times n$ is the sum of its diagonal entries,

$$\operatorname{Tr}(A) = \sum_{i=1}^{n} a_{ii}.$$

If λ is a scalar and square matrices A and B have the same size, then

$$\operatorname{Tr}(A + B) = \operatorname{Tr}(A) + \operatorname{Tr}(B), \quad \operatorname{Tr}(\lambda A) = \lambda \operatorname{Tr}(A), \quad \operatorname{Tr}(AB) = \operatorname{Tr}(BA),$$

► **Minors. Rank and defect of a matrix.** In a square or rectangular matrix, let us select k arbitrary rows and k arbitrary columns to make up a square submatrix. The kth-order determinant formed by the entries where the selected rows and columns intersect is called a kth-order *minor* of the matrix.

The *rank of a matrix* A is the maximum order of nonzero minors of A. The rank of a matrix A is denoted $\operatorname{rank}(A)$. If all entries of a matrix are zero, the rank of the matrix is taken to be zero.

Properties of the rank of a matrix:

1. The rank of a matrix does not change if: a row (column) whose entries are all zero is deleted; some rows (columns) are interchanged; a row (column) is multiplied by a nonzero number; the entries of one row (column) multiplied by any number are added to the respective entries of another row (column); and the rows are substituted by columns while the columns are substituted by the respective rows (for square matrices).

Example 3. Find the rank of the matrix $A = \begin{pmatrix} 1 & 2 & 3 & 6 \\ 2 & 3 & 1 & 6 \\ 3 & 1 & 2 & 6 \end{pmatrix}$.

Subtract the sum of the first three columns from column 4 and then delete the resulting column, whose entries are now all zero, to obtain the matrix $A_1 = \begin{pmatrix} 1 & 2 & 3 \\ 2 & 3 & 1 \\ 3 & 1 & 2 \end{pmatrix}$, which has the same rank as A. Since $\det(A_1) = -18 \neq 0$, we have $\operatorname{rank}(A_1) = 3$, and hence $\operatorname{rank}(A) = 3$.

2. For any matrices A and B of the same size the following inequality holds:

$$\operatorname{rank}(A + B) \le \operatorname{rank}(A) + \operatorname{rank}(B).$$

3. For a matrix A of size $m \times n$ and a matrix B of size $n \times k$, the *Sylvester inequalities* hold:

$$\operatorname{rank}(A) + \operatorname{rank}(B) - n \le \operatorname{rank}(AB) \le \min\{\operatorname{rank}(A), \operatorname{rank}(B)\}.$$

For a square matrix A of size $n \times n$, the value $d = n - \operatorname{rank}(A)$ is called the *defect* of the matrix A, and A is called a *d-fold degenerate matrix*. The rank of a nondegenerate square matrix $A \equiv [a_{ij}]$ of size $n \times n$ is equal to n.

4. Let r be the rank of a matrix; basic minor of this matrix is its nonzero minor of the order r. Basic rows (columns) of the matrix are the rows (columns) forming the basic minor.

THEOREM ON BASIC MINOR. *Basic rows (resp., basic columns) of a matrix are linearly independent. Any row (resp., any column) of a matrix is a linear combination of its basic rows (resp., columns).*

► **Linear dependence of row vectors (column vectors).** A row vector (column vector) B is a *linear combination* of row vectors (column vectors) $A_1, \dots, A_k$ if there exist scalars $\alpha_1, \dots, \alpha_k$ such that

$$B = \alpha_1 A_1 + \cdots + \alpha_k A_k.$$

Row vectors (column vectors) $A_1, \dots, A_k$ are said to be *linearly dependent* if there exist scalars $\alpha_1, \dots, \alpha_k$ ($\alpha_1^2 + \cdots + \alpha_k^2 \neq 0$) such that

$$\alpha_1 A_1 + \cdots + \alpha_k A_k = O,$$

where O is the zero row vector (column vector).

Row vectors (column vectors) $A_1, \dots, A_k$ are said to be *linearly independent* if, for any $\alpha_1, \dots, \alpha_k$ ($\alpha_1^2 + \cdots + \alpha_k^2 \neq 0$) we have

$$\alpha_1 A_1 + \cdots + \alpha_k A_k \neq O.$$

Remark. Row vectors (column vectors) $A_1, \dots, A_k$ are linearly dependent if and only if at least one of them is a linear combination of the others.

► **Determinant of a matrix.** For any square matrix A of the form (M5.2.2.1), one can calculate its determinant (M5.2.1.1), denoted $\det A$, $\det(A)$, or $|A|$.

The determinant of a matrix has the following properties:

1. The determinant of a triangular (upper or lower) and a diagonal matrices is equal to the product of its entries on the main diagonal. In particular, the determinant of the unit matrix is equal to 1.
2. The determinant of the product of two matrices A and B of the same size is equal to the product of their determinants,

$$\det(AB) = \det A \det B.$$

3. The determinant is invariant under matrix transposition:

$$\det A = \det A^T.$$

M5.2.3. Inverse Matrix. Functions of Matrices

► **Inverse matrices.** Let A be an $n\times n$ square matrix and let I be the unit matrix of the same size.

A square matrix A is called *nonsingular* or *nondegenerate* if $\det A \neq 0$.

THEOREM. *A square matrix is nondegenerate if and only if its rows (columns) are linearly independent.*

A square matrix A is called *invertible* if one can find a matrix B such that $AB = BA = I$. The matrix B is called the *inverse* of A and denoted A^{-1}. An invertible matrix A has a unique inverse.

THEOREM. *A square matrix A is invertible if and only if its determinant is nonzero (i.e., A is nonsingular).*

If the matrix A is defined by the table (M5.2.2.1), then its inverse is calculated as

$$A^{-1} = \begin{pmatrix} \frac{A_{11}}{\det A} & \frac{A_{21}}{\det A} & \cdots & \frac{A_{n1}}{\det A} \\ \frac{A_{12}}{\det A} & \frac{A_{22}}{\det A} & \cdots & \frac{A_{n2}}{\det A} \\ \vdots & \vdots & \ddots & \vdots \\ \frac{A_{1n}}{\det A} & \frac{A_{2n}}{\det A} & \cdots & \frac{A_{nn}}{\det A} \end{pmatrix}. \qquad \text{(M5.2.3.1)}$$

where A_{ij} is the cofactor of the element a_{ij} of the determinant of A; the definition of A_{ij} can be found after formula (M5.2.1.2).

Properties of the inverse of a matrix:

$$(AB)^{-1} = B^{-1}A^{-1}, \quad (\lambda A)^{-1} = \frac{1}{\lambda}A^{-1},$$
$$(A^{-1})^{-1} = A, \quad (A^{-1})^T = (A^T)^{-1}, \quad (A^{-1})^* = (A^*)^{-1},$$

where the square matrices A and B are assumed to be nonsingular and the scalar λ to be nonzero.

► **Powers of square matrices.** The product of several identical square matrices A can be written as a *positive integer power* of the matrix A: $AA = A^2$, $AAA = A^2A = A^3$, etc. For a positive integer k, one defines $A^k = A^{k-1}A$ as the kth power of A. For a nondegenerate matrix A, one defines $A^0 = AA^{-1} = I$, $A^{-k} = (A^{-1})^k$. Powers of a matrix have the following properties:

$$A^pA^q = A^{p+q}, \quad (A^p)^q = A^{pq},$$

where p and q are arbitrary positive integers and A is an arbitrary square matrix; or p and q are arbitrary integers and A is an arbitrary nondegenerate matrix.

There exist matrices A^k whose positive integer power is equal to the zero matrix, even if $A \neq O$. If $A^k = O$ for some integer $k > 1$, then A is called a *nilpotent matrix*.

A matrix A is said to be *involutive* if it coincides with its inverse: $A = A^{-1}$ or $A^2 = I$.

► **Polynomials and functions of matrices.** A *polynomial with matrix argument* is the expression obtained from a scalar polynomial $f(x)$ by replacing the scalar argument x with a square matrix X:

$$f(X) = a_0I + a_1X + a_2X^2 + \cdots,$$

where a_i $(i = 0, 1, 2, \ldots)$ are real or complex coefficients. The polynomial $f(X)$ is a square matrix of the same size as X.

The exponential function of a square matrix X can be represented as the following convergent series:

$$e^X = 1 + X + \frac{X^2}{2!} + \frac{X^3}{3!} + \cdots = \sum_{k=0}^{\infty} \frac{X^k}{k!}.$$

The inverse matrix has the form

$$(e^X)^{-1} = e^{-X} = 1 - X + \frac{X^2}{2!} - \frac{X^3}{3!} + \cdots = \sum_{k=0}^{\infty} (-1)^k \frac{X^k}{k!}.$$

Remark. Note that $e^Xe^Y \neq e^Ye^X$, in general. The relation $e^Xe^Y = e^{X+Y}$ holds only for commuting matrices X and Y.

Some other functions of matrices can be expressed in terms of the exponential function:

$$\sin X = \frac{1}{2i}(e^{iX} - e^{-iX}), \quad \cos X = \frac{1}{2}(e^{iX} + e^{-iX}),$$
$$\sinh X = \frac{1}{2}(e^X - e^{-X}), \quad \cosh X = \frac{1}{2}(e^X + e^{-X}).$$

M5.2.4. Eigenvalues and Characteristic Equation of a Matrix. The Cayley–Hamilton Theorem

► **Eigenvalues and spectra of square matrices.** An *eigenvalue* of a square matrix A is any real or complex λ for which the matrix $F(\lambda) \equiv A - \lambda I$ is degenerate. The set of all eigenvalues of a matrix A is called its *spectrum*, and $F(\lambda)$ is called its *characteristic matrix*. The inverse of an eigenvalue, $\mu = 1/\lambda$, is called a *characteristic value*.

A square matrix is nondegenerate if and only if all its eigenvalues are different from zero.

A nonzero (column) vector X satisfying the condition

$$AX = \lambda X$$

is called an *eigenvector of the matrix A* corresponding to the eigenvalue λ. Eigenvectors corresponding to distinct eigenvalues of A are linearly independent.

► **Characteristic equation of a matrix.** The algebraic equation of degree n

$$f_A(\lambda) \equiv \det(A - \lambda I) \equiv \det\,[a_{ij} - \lambda\delta_{ij}] \equiv \begin{vmatrix} a_{11}-\lambda & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22}-\lambda & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{n1} & a_{n2} & \cdots & a_{nn}-\lambda \end{vmatrix} = 0$$

is called the *characteristic equation* of the matrix A of size $n \times n$, and $f_A(\lambda)$ is called its *characteristic polynomial*. The spectrum of the matrix A (i.e., the set of all its eigenvalues) coincides with the set of all roots of its characteristic equation.

Example 1. The characteristic equation of the matrix

$$A = \begin{pmatrix} 4 & -8 & 1 \\ 5 & -9 & 1 \\ 4 & -6 & -1 \end{pmatrix}$$

has the form

$$f_A(\lambda) \equiv \det \begin{pmatrix} 4-\lambda & -8 & 1 \\ 5 & -9-\lambda & 1 \\ 4 & -6 & -1-\lambda \end{pmatrix} = -\lambda^3 - 6\lambda^2 - 11\lambda - 6 = -(\lambda+1)(\lambda+2)(\lambda+3) = 0.$$

Therefore the spectrum of the matrix A consists of three eigenvalues: $\lambda_1 = -1$, $\lambda_2 = -2$, and $\lambda_3 = -3$.

Let λ_j be an eigenvalue of a square matrix A. Then:

1) $\alpha\lambda_j$ is an eigenvalue of the matrix αA for any scalar α;
2) λ_j^p is an eigenvalue of the matrix A^p ($p = 0, \pm 1, \ldots, \pm N$ for a nondegenerate A; otherwise, $p = 0, 1, \ldots, N$), where N is a natural number;
3) a polynomial $f(A)$ of the matrix A has the eigenvalue $f(\lambda)$.

The matrix power series $\sum\limits_{k=0}^{\infty} \alpha_k A^k$ is convergent if and only if the power series $\sum\limits_{k=0}^{\infty} \alpha_k \lambda_j^k$ is convergent for each eigenvalue λ_j of A.

Regarding bounds for eigenvalues, see Subsection M5.1.5.

Let the positive integer s_i be the *multiplicity* of the eigenvalue λ_i of the characteristic equation of the matrix A of size $n \times n$. Note that $\sum\limits_i s_i = n$.

The determinant $\det A$ is equal to the product of all eigenvalues of A, each eigenvalue counted according to its multiplicity, i.e.,

$$\det A = \prod_i \lambda_i^{s_i}.$$

The trace $\mathrm{Tr}(A)$ is equal to the sum of all eigenvalues of A, each eigenvalue counted according to its multiplicity, i.e.,

$$\mathrm{Tr}(A) = \sum_i s_i \lambda_i.$$

► **Cayley–Hamilton theorem. Sylvester theorem.**

CAYLEY–HAMILTON THEOREM. *Each square matrix A satisfies its own characteristic equation; i.e., $f_A(A) = 0$.*

Example 2. Let us illustrate the Cayley–Hamilton theorem by the matrix in Example 1:

$$\begin{aligned} f_A(A) &= -A^3 - 6A^2 - 11A - 6I \\ &= -\begin{pmatrix} 70 & -116 & 19 \\ 71 & -117 & 19 \\ 64 & -102 & 11 \end{pmatrix} - 6\begin{pmatrix} -20 & 34 & -5 \\ -21 & 35 & -5 \\ -18 & 28 & -1 \end{pmatrix} - 11\begin{pmatrix} 4 & -8 & 1 \\ 5 & -9 & 1 \\ 4 & -6 & -1 \end{pmatrix} - 6\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} = O. \end{aligned}$$

A scalar polynomial $p(\lambda)$ is called an *annihilating polynomial* of a square matrix A if $p(A) = 0$. For example, the characteristic polynomial $f_A(\lambda)$ is an annihilating polynomial of A. The unique monic annihilating polynomial of least degree is called the *minimal polynomial* of A and is denoted by $\psi(\lambda)$. The minimal polynomial is a divisor of every annihilating polynomial.

By dividing an arbitrary polynomial $f(\lambda)$ of degree n by an annihilating polynomial $p(\lambda)$ of degree m ($p(\lambda) \neq 0$), one obtains the representation

$$f(\lambda) = p(\lambda)q(\lambda) + r(\lambda),$$

where $q(\lambda)$ is a polynomial of degree $n - m$ (if $m \le n$) or $q(\lambda) = 0$ (if $m > n$) and $r(\lambda)$ is a polynomial of degree $l < m$ or $r(\lambda) = 0$. Hence

$$f(A) = p(A)q(A) + r(A),$$

where $p(A) = 0$ and $f(A) = r(A)$. The polynomial $r(\lambda)$ in this representation is called the *interpolation polynomial* of A.

Example 3. Let

$$f(A) = A^4 + 4A^3 + 2A^2 - 12A - 10I,$$

where the matrix A is defined in Example 1. Dividing $f(\lambda)$ by the characteristic polynomial $f_A(\lambda) = -\lambda^3 - 6\lambda^2 - 11\lambda - 6$, we obtain the remainder $r(\lambda) = 3\lambda^2 + 4\lambda + 2$. Consequently,

$$f(A) = r(A) = 3A^2 + 4A + 2I.$$

The Cayley–Hamilton theorem can also be used to find the powers and the inverse of a matrix A (since if $f_A(A) = 0$, then $A^k f_A(A) = 0$ for any positive integer k).

Example 4. For the matrix in Examples 1–3, one has

$$f_A(A) = -A^3 - 6A^2 - 11A - 6I = 0.$$

Hence we obtain

$$A^3 = -6A^2 - 11A - 6I.$$

By multiplying this expression by A, we obtain

$$A^4 = -6A^3 - 11A^2 - 6A.$$

Now we use the representation of the cube of A via lower powers of A and eventually arrive at the formula

$$A^4 = 25A^2 + 60A + 36I.$$

For the inverse matrix, by analogy with the preceding, we obtain

$$A^{-1} f_A(A) = A^{-1}(-A^3 - 6A^2 - 11A - 6I) = -A^2 - 6A - 11I - 6A^{-1} = 0.$$

The definitive result is

$$A^{-1} = -\frac{1}{6}(A^2 + 6A + 11I).$$

THEOREM. *Every analytic function of a square $n \times n$ matrix A can be represented as a polynomial of the same matrix,*

$$f(A) = \frac{1}{\Delta(\lambda_1, \lambda_2, \ldots, \lambda_n)} \sum_{k=1}^{n} \Delta_{n-k} A^{n-k},$$

where $\Delta(\lambda_1, \lambda_2, \ldots, \lambda_n)$ is the Vandermonde determinant

$$\Delta(\lambda_1, \lambda_2, \ldots, \lambda_n) \equiv \begin{vmatrix} 1 & 1 & \cdots & 1 \\ \lambda_1 & \lambda_2 & \cdots & \lambda_n \\ \lambda_1^2 & \lambda_2^2 & \cdots & \lambda_n^2 \\ \vdots & \vdots & \ddots & \vdots \\ \lambda_1^{n-1} & \lambda_2^{n-1} & \cdots & \lambda_n^{n-1} \end{vmatrix} = \prod_{1 \le j < i \le n} (\lambda_i - \lambda_j)$$

and Δ_i *is obtained from* Δ *by replacing the* $(i+1)$*st row by* $(f(\lambda_1), f(\lambda_2), \dots, f(\lambda_n))$.

In some cases, an analytic function of a matrix A can be computed by a formula in the following theorem.

SYLVESTER'S THEOREM. *If all eigenvalues of a matrix* A *are distinct, then*

$$f(A) = \sum_{k=1}^{n} f(\lambda_k) Z_k, \qquad Z_k = \frac{\prod_{i\neq k}(A - \lambda_i I)}{\prod_{i\neq k}(\lambda_k - \lambda_i)}.$$

M5.3. Systems of Linear Algebraic Equations

M5.3.1. Consistency Condition for a Linear System

► **Notion of a system of linear algebraic equations.** A *system of* m *linear equations with* n *unknown quantities* has the form

$$\begin{aligned} &a_{11}x_1 + a_{12}x_2 + \cdots + a_{1k}x_k + \cdots + a_{1n}x_n = b_1,\\ &a_{21}x_1 + a_{22}x_2 + \cdots + a_{2k}x_k + \cdots + a_{2n}x_n = b_2,\\ &\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\\ &a_{m1}x_1 + a_{m2}x_2 + \cdots + a_{mk}x_k + \cdots + a_{mn}x_n = b_m, \end{aligned} \tag{M5.3.1.1}$$

where $a_{11}, a_{12}, \dots, a_{mn}$ are the *coefficients of the system*; $b_1, b_2, \dots, b_m$ are its *constant terms*; and $x_1, x_2, \dots, x_n$ are the unknown quantities.

System (M5.3.1.1) is said to be *homogeneous* if all its constant terms are equal to zero. Otherwise (i.e., if there is at least one nonzero free term) the system is called *nonhomogeneous*.

If the number of equations is equal to that of the unknown quantities ($m = n$), system (M5.3.1.1) is called a *square system*.

A *solution* of system (M5.3.1.1) is a set of n numbers $x_1, x_2, \dots, x_n$ satisfying the equations of the system. A system is said to be *consistent* if it admits at least one solution. If a system has no solutions, it is said to be *inconsistent*. A consistent system of the form (M5.3.1.1) is called a *determined system* if it has a unique solution. A consistent system with more than one solution is said to be *undetermined*.

It is convenient to use matrix notation for systems of the form (M5.3.1.1),

$$AX = B, \tag{M5.3.1.2}$$

where $A \equiv [a_{ij}]$ is a matrix of size $m\times n$ called the *basic matrix* of the system; $X \equiv [x_i]$ is a column vector of size n; $B \equiv [b_i]$ is a column vector of size m.

► **Consistency condition for a general linear system.** System (M5.3.1.1) or (M5.3.1.2) is associated with two matrices: the basic matrix A of size $m\times n$ and the *augmented matrix* A_1 of size $m\times(n+1)$ formed by the matrix A supplemented with the column of the constant terms, i.e.,

$$A = \begin{pmatrix} a_{11} & a_{12} & \cdots & a_{1n}\\ a_{21} & a_{22} & \cdots & a_{2n}\\ \vdots & \vdots & \ddots & \vdots\\ a_{m1} & a_{m2} & \cdots & a_{mn} \end{pmatrix}, \quad A_1 = \begin{pmatrix} a_{11} & a_{12} & \cdots & a_{1n} & b_1\\ a_{21} & a_{22} & \cdots & a_{2n} & b_2\\ \vdots & \vdots & \ddots & \vdots & \vdots\\ a_{m1} & a_{m2} & \cdots & a_{mn} & b_m \end{pmatrix}. \tag{M5.3.1.3}$$

KRONECKER–CAPELLI THEOREM. *A linear system (M5.3.1.1) or (M5.3.1.2) is consistent if and only if its basic matrix and its augmented matrix (M5.3.1.3) have the same rank, i.e.,* $\operatorname{rank}(A_1) = \operatorname{rank}(A)$.

► **Equivalent systems of equations. The elementary transformations.** Two systems are said to be *equivalent* if their sets of solutions coincide.

Systems of linear equations can be simplified using the following three types of elementary transformations:

1. Interchange of two equations (or the corresponding rows of the augmented matrix).
2. Multiplication of both sides of one equation (or the corresponding row of the augmented matrix) by a nonzero constant.
3. Adding to both sides of one equation both sides of another equation multiplied by a constant (adding to some row of the augmented matrix its other row multiplied by a constant).

Under the above elementary transformations, a system of linear equations reduces to an equivalent system of equations.

M5.3.2. Finding Solutions of a System of Linear Equations

► **System of two equations with two unknown quantities.** A system of two equations with two unknown quantities has the form

$$\begin{aligned} a_1x+b_1y&=c_1,\\ a_2x+b_2y&=c_2. \end{aligned} \qquad \text{(M5.3.2.1)}$$

Depending on the coefficients a_k, b_k, c_k, the following three cases are possible:

1°. If $\Delta=a_1b_2-a_2b_1\neq 0$, then system (M5.3.2.1) has a unique solution,

$$x=\frac{c_1b_2-c_2b_1}{a_1b_2-a_2b_1},\qquad y=\frac{a_1c_2-a_2c_1}{a_1b_2-a_2b_1}.$$

2°. If $\Delta=a_1b_2-a_2b_1=0$ and $a_1c_2-a_2c_1=0$ (the case of proportional coefficients), then system (M5.3.2.1) has infinitely many solutions described by the formulas

$$x=t,\qquad y=\frac{c_1-a_1t}{b_1}\qquad (b_1\neq 0),$$

where t is arbitrary.

3°. If $\Delta=a_1b_2-a_2b_1=0$ and $a_1c_2-a_2c_1\neq 0$, then system (M5.3.2.1) has no solutions.

► **General square system of linear equations with $m = n$.** A square system of linear equations has the form (M5.3.1.1) with $m=n$.

1°. *Cramer's rule.* If the determinant of the matrix of system (M5.3.1.1) with $m=n$ is different from zero, i.e., $\Delta=\det A\neq 0$, then the system admits a unique solution, which is expressed by formulas

$$x_1=\frac{\Delta_1}{\Delta},\quad x_2=\frac{\Delta_2}{\Delta},\quad \dots,\quad x_n=\frac{\Delta_n}{\Delta}, \qquad \text{(M5.3.2.2)}$$

where Δ_k ($k=1, 2, \dots, n$) is the determinant of the matrix obtained from A by replacing its kth column with the column of constant terms:

$$\Delta_k=\begin{vmatrix} a_{11} & a_{12} & \cdots & a_{1\,k-1} & b_1 & a_{1\,k+1} & \cdots & a_{1n}\\ a_{21} & a_{22} & \cdots & a_{2\,k-1} & b_2 & a_{2\,k+1} & \cdots & a_{2n}\\ \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots\\ a_{n1} & a_{n2} & \cdots & a_{n\,k-1} & b_n & a_{n\,k+1} & \cdots & a_{nn} \end{vmatrix}.$$

Example 1. Using Cramer's rule, let us find the solution of the system of linear equations

$$\begin{aligned} 2x_1 + x_2 + 4x_3 &= 16,\\ 3x_1 + 2x_2 + x_3 &= 10,\\ x_1 + 3x_2 + 3x_3 &= 16. \end{aligned}$$

The determinant of its basic matrix is different from zero,

$$\Delta = \begin{vmatrix} 2 & 1 & 4\\ 3 & 2 & 1\\ 1 & 3 & 3 \end{vmatrix} = 26 \neq 0,$$

and we have

$$\Delta_1 = \begin{vmatrix} 16 & 1 & 4\\ 10 & 2 & 1\\ 16 & 3 & 3 \end{vmatrix} = 26, \quad \Delta_2 = \begin{vmatrix} 2 & 16 & 4\\ 3 & 10 & 1\\ 1 & 16 & 3 \end{vmatrix} = 52, \quad \Delta_3 = \begin{vmatrix} 2 & 1 & 16\\ 3 & 2 & 10\\ 1 & 3 & 16 \end{vmatrix} = 78.$$

Therefore, by Cramer's rule (M5.3.2.2), the only solution of the system has the form

$$x_1 = \frac{\Delta_1}{\Delta} = \frac{26}{26} = 1, \quad x_2 = \frac{\Delta_2}{\Delta} = \frac{52}{26} = 2, \quad x_3 = \frac{\Delta_3}{\Delta} = \frac{78}{26} = 3.$$

2°. System (M5.3.1.1) with $m = n$ can be treated in the matrix form (M5.3.1.2) where A is a square matrix. If $\det A \neq 0$, the system has a unique solution

$$X = A^{-1}B,$$

expressed in terms of the inverse A^{-1}, which can be found by formula (M5.2.3.1).

3°. *Reduction of a system to a triangular form* (*Gaussian method*). Suppose that $\det A \neq 0$. The Gaussian method is based on elementary transformations (see Subsection M5.3.1) used for the reduction of a given system to an equivalent system having the triangular form

$$\begin{aligned} x_1 + \alpha_{12}x_2 + \alpha_{13}x_3 + \cdots + \alpha_{1n}x_n &= \beta_1,\\ x_2 + \alpha_{23}x_3 + \cdots + \alpha_{2n}x_n &= \beta_2,\\ \cdots\cdots\cdots\cdots\cdots\cdots\cdots &\\ x_{n-1} + \alpha_{n-1,n}x_n &= \beta_{n-1},\\ x_n &= \beta_n. \end{aligned}$$

This system can be easily solved: inserting $x_n = \beta_n$ (from the last equation) into the preceding $(n-1)$st equation, one finds x_{n-1}. Then, inserting the values obtained for x_n, x_{n-1} into the $(n-2)$nd equation, one finds x_{n-2}. Proceeding in this way, one finally finds x_1. This back substitution process is described by the formulas

$$x_k = \beta_k - \sum_{s=k+1}^{n} \alpha_{ks}x_s \quad (k = n-1, n-2, \dots, 1).$$

Example 2. Solve the system

$$\begin{aligned} x_1 + x_2 - 2x_3 &= -2,\\ 2x_1 + 3x_2 + x_3 &= 9,\\ 3x_1 + 2x_2 + 2x_3 &= 7. \end{aligned}$$

Multiply the first equation by –2 and add to the second one. Multiply the first equation by –3 and add to the third one. As a result, the first equation together with the two obtained make up the equivalent system

$$\begin{aligned} x_1 + x_2 - 2x_3 &= -2,\\ x_2 + 5x_3 &= 13,\\ -x_2 + 8x_3 &= 13. \end{aligned}$$

Adding together the last two equations and dividing the result by 13, one arrives at the triangular system

$$\begin{aligned} x_1 + x_2 - 2x_3 &= -2,\\ x_2 + 5x_3 &= 13,\\ x_3 &= 2. \end{aligned}$$

Solving this system from bottom to top, one finds that

$$x_3 = 2, \quad x_2 = 13 - 5x_3 = 3, \quad x_1 = -2 - x_2 + 2x_3 = -1.$$

4°. *The Jordan–Gauss method*. Let us introduce some definitions. An unknown x_i is called *resolved* or *basic* if it enters only in one equation of the system with coefficient 1 and is not contained in the other equations.

If each equation of the system contains a resolved unknown, this system is called *resolved*. The unknowns of the system that are not basic are called *free*.

In order to find all solutions of a consistent system of linear equations, it suffices to find an equivalent resolved system. If all the unknowns happen to be basic, the resolved system gives the values of these unknowns. Otherwise, the basic unknowns are expressed in terms of the free ones.

Description of the method. Let us write down the system of linear equations (M5.3.1.1) as the table

x_1	$\cdots$	x_k	$\cdots$	x_n	
a_{11}	$\cdots$	a_{1k}	$\cdots$	a_{1n}	b_1
$\cdots$	$\cdots$	$\cdots$	$\cdots$	$\cdots$	$\cdots$
a_{r1}	$\cdots$	a_{rk}	$\cdots$	a_{rn}	b_r
$\cdots$	$\cdots$	$\cdots$	$\cdots$	$\cdots$	$\cdots$
a_{m1}	$\cdots$	a_{mk}	$\cdots$	a_{mn}	b_m

For a resolving entry $a_{rk} \neq 0$, the following procedure is called the *Jordan transformation*:

1) multiply the rth row of the table by $1/a_{rk}$;

2) add the resulting rth row multiplied by $-a_{1k}$ to the first row;

3) add the rth row multiplied by $-a_{2k}$ to the second row; and so on for all remaining rows.

After that, the unknown x_k becomes resolved, with all entries of the kth column equal to zero except that $a_{rk} = 1$.

By choosing other resolving entries in different rows and performing the respective Jordan transformations, one arrives at a resolved system equivalent to the original one.

If, at some point, the coefficients of the unknowns in a row become all zero and the free term of that row is nonzero, then the system of equations is inconsistent. If all entries of a row, including the free term, become zero, then this row is crossed out from the table.

Example 3. Solve the system of equations

$$\begin{aligned} 2x_1 - 3x_2 + 5x_3 &= 1,\\ x_1 + 2x_2 - 3x_3 &= -7,\\ 2x_1 \phantom{{}+2x_2} + 5x_3 &= 4. \end{aligned}$$

Rewrite this system as a table and reduce it to a resolved form in six steps:

$$\begin{array}{r|r|r|r} x_1 & x_2 & x_3 & \\ \hline 2 & -3 & 5 & 1\\ \boxed{1} & 2 & -3 & -7\\ 2 & 0 & 5 & 4 \end{array} \Longrightarrow \begin{array}{r|r|r|r} x_1 & x_2 & x_3 & \\ \hline 0 & -7 & 11 & 15\\ 1 & 2 & -3 & -7\\ 0 & -4 & 11 & 18 \end{array} \Longrightarrow \begin{array}{r|r|r|r} x_1 & x_2 & x_3 & \\ \hline 0 & -7 & 11 & 15\\ 1 & 2 & -3 & -7\\ 0 & 3 & 0 & 3 \end{array}$$

$$\Longrightarrow \begin{array}{r|r|r|r} x_1 & x_2 & x_3 & \\ \hline 0 & -7 & 11 & 15\\ 1 & 2 & -3 & -7\\ 0 & \boxed{1} & 0 & 1 \end{array} \Longrightarrow \begin{array}{r|r|r|r} x_1 & x_2 & x_3 & \\ \hline 0 & 0 & 11 & 22\\ 1 & 0 & -3 & -9\\ 0 & 1 & 0 & 1 \end{array} \Longrightarrow \begin{array}{r|r|r|r} x_1 & x_2 & x_3 & \\ \hline 0 & 0 & \boxed{1} & 2\\ 1 & 0 & -3 & -9\\ 0 & 1 & 0 & 1 \end{array} \Longrightarrow \begin{array}{r|r|r|r} x_1 & x_2 & x_3 & \\ \hline 0 & 0 & 1 & 2\\ 1 & 0 & 0 & -3\\ 0 & 1 & 0 & 1 \end{array}$$

In the tables above, the resolving entries are boxed. The following sequence of actions has been performed: (1) double the second row has been subtracted from the first and third ones, (2) the first row has been subtracted from the third one, (3) the third row has been divided by 3, (4) the third row multiplied by 7 (resp., by –2) has been added to the first (resp., second) one, (5) the first row has been divided by 11, and (6) the first row multiplied by 3 has been added to the second one. Thus, the original system acquires the resolved form

$$\begin{cases} 0\cdot x_1 + 0\cdot x_2 + 1\cdot x_3 = 2, \\ 1\cdot x_1 + 0\cdot x_2 + 0\cdot x_3 = -3, \\ 0\cdot x_1 + 1\cdot x_2 + 0\cdot x_3 = 1. \end{cases}$$

The resulting solution is $x_1 = -3$, $x_2 = 1$, $x_3 = 2$.

Example 4. Solve the system of equations

$$\begin{cases} 2x_1 + 7x_2 + 3x_3 + x_4 = 6, \\ 3x_1 + 5x_2 + 2x_3 + 2x_4 = 4, \\ 9x_1 + 4x_2 + x_3 + 7x_4 = 2. \end{cases}$$

With Jordan transformations, this system is reduced to the resolved form

$$\begin{cases} - 11x_2 - 5x_3 + x_4 = -10, \\ x_1 + 9x_2 + 4x_3 \phantom{{}+x_4} = 8. \end{cases}$$

Hence, the set of all solutions to the original system is given by

$$x_1 = 8 - 9x_2 - 4x_3, \quad x_4 = -10 + 11x_2 + 5x_3,$$

with x_2 and x_3 assuming any real values.

► **General system of m linear equations with n unknown quantities.** Suppose that system (M5.3.1.1) is consistent and its basic matrix A has rank r. First, in the matrix A, one finds a submatrix of size $r\times r$ with a nonzero rth-order determinant and drops the $m-r$ equations whose coefficients do not belong to this submatrix (the dropped equations follow from the remaining ones and can, therefore, be neglected). In the remaining equations, the $n-r$ unknown quantities (free unknown quantities) that are not involved in the said submatrix should be transferred to the right-hand sides. Thus, one obtains a system of r equations with r unknown quantities, which can be solved by any of the methods described above in the current subsection.

Remark. If the rank r of the basic matrix and the rank of the augmented matrix of system (M5.3.1.1) are equal to the number of the unknown quantities n, then the system has a unique solution.

► **Existence of nontrivial solutions of a homogeneous system.** Consider the homogeneous system (M5.3.1.1), with $b_1 = b_2 = \cdots = b_m = 0$. This system is always consistent, since it always has the so-called *trivial solution* $x_1 = x_2 = \cdots = x_n = 0$.

THEOREM. *A homogeneous system has a nontrivial solution if and only if the rank of the matrix A is less than the number of the unknown quantities n.*

It follows that a square homogeneous system has a nontrivial solution if and only if the determinant of its matrix of coefficients is equal to zero, $\det A = 0$.

M5.4. Quadratic Forms

M5.4.1. Quadratic Forms and Their Transformations

► **Quadratic form with n variables.** A real quadratic form is a homogeneous polynomial of degree 2 in n variables $x_1, x_2, \ldots, x_n$ of the form

$$A_n(x_1, x_2, \ldots, x_n) \equiv \sum_{i,j=1}^{n} a_{ij}x_ix_j, \qquad \text{(M5.4.1.1)}$$

with real coefficients a_{ij} satisfying the symmetry condition $a_{ij} = a_{ji}$.

The quadratic form (M5.4.1.1) can be conveniently written in short matrix notation

$$A_n(X) = X^T A X, \qquad \text{(M5.4.1.2)}$$

where $X \equiv [x_i]$ is a column vector consisting of n elements, X^T is its transpose, and $A \equiv [a_{ij}]$ is an $n \times n$ symmetric matrix, called the *matrix of the quadratic form*.

A real-valued quadratic form $A_n(X)$ is said to be:

a) *positive definite* (resp., *negative definite*) if $A_n(X) > 0$ (resp., $A_n(X) < 0$) for any $X \neq 0$;
b) *indefinite* if there exist vectors X and Y such that $A_n(X) > 0$ and $A_n(Y) < 0$;
c) *nonnegative* (resp., *nonpositive*) if $A_n(X) \geq 0$ (resp., $A_n(X) \leq 0$) for all $X \neq 0$.

The determinant $\det A$ of the matrix A is called the *discriminant of the quadratic form* $A_n(X)$. A quadratic form is called *degenerate* if its discriminant is zero.

► **Criteria of positive and negative definiteness of a quadratic form.**

1°. A real quadratic form $A_n(X)$ is positive definite, negative definite, indefinite, nonnegative, nonpositive if the eigenvalues λ_i of its matrix $A \equiv [a_{ij}]$ are all positive, are all negative, some are positive and some negative, are all nonnegative, are all nonpositive, respectively.

2°. *Sylvester criterion.* A real quadratic form $A_n(X)$ is positive definite if and only if it satisfies the conditions

$$\Delta_1 \equiv a_{11} > 0, \quad \Delta_2 \equiv \begin{vmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{vmatrix} > 0, \quad \dots, \quad \Delta_n \equiv \det A > 0.$$

If the signs of the minor determinants alternate,

$$\Delta_1 < 0, \quad \Delta_2 > 0, \quad \Delta_3 < 0, \dots,$$

then the quadratic form is negative definite.

► **Transformations of a real quadratic form.** Let us find out how the coefficient matrix changes under a linear transformation of the variables

$$x_i = \sum_{k=1}^{n} b_{ik} y_k \qquad (i = 1,\, 2,\, \dots, n), \qquad \text{(M5.4.1.3)}$$

where b_{ik} are real numbers. In matrix notation, transformation (M5.4.1.3) becomes

$$X = BY, \qquad \text{(M5.4.1.4)}$$

where $Y \equiv [y_i]$ is a column vector of size n and $B \equiv [b_{ij}]$ is a transformation matrix of size $n \times n$.

Substituting (M5.4.1.4) into (M5.4.1.2) gives

$$A_n(X) = Y^T B^T A B Y = Y^T \widetilde{A} Y = \widetilde{A}_n(Y),$$

where

$$\widetilde{A} = B^T A B. \qquad \text{(M5.4.1.5)}$$

It follows that the discriminant of a quadratic form changes according to the rule

$$\det \widetilde{A} = \det A \, (\det B)^2.$$

In what follows, only nondegenerate transformations of variables are considered, i.e., those with $\det B \neq 0$. The rank of the coefficient matrix remains unchanged under such transformations. The rank of the coefficient matrix is usually said to be the *rank of the quadratic form*.

M5.4.2. Canonical and Normal Representations of a Quadratic Form

► **Canonical representation of a quadratic form.** Any real quadratic form (M5.4.1.1) can be reduced to the form

$$A_n(X) = \sum_{i=1}^{r} \lambda_i y_i^2 \equiv A_r(Y) \qquad \text{(M5.4.2.1)}$$

using an appropriate nondegenerate linear transformation (M5.4.1.3).

This representation is called a *canonical representation* of the quadratic form, the real coefficients $\lambda_1, \ldots, \lambda_r$ are called the *canonical coefficients*.

Reduction of the quadratic form (M5.4.1.1) to the canonical form (M5.4.2.1) is not unique and can be performed using various linear transformations of the form (M5.4.1.3).

LAW OF INERTIA OF QUADRATIC FORMS. *The number of terms with positive coefficients and the number of terms with negative coefficients in any canonical representation of a real quadratic form does not depend on the method used to obtain such a representation.*

The *index of inertia* of a real quadratic form is the integer r equal to the number of nonzero coefficients in its canonical representation (this number coincides with the rank of the quadratic form). Its *positive index of inertia* is the integer p equal to the number of positive coefficients in the canonical representation of the form, and its *negative index of inertia* is the integer q equal to the number of its negative canonical coefficients. The integer $s = p - q$ is called the *signature* of the quadratic form.

A real quadratic form $A_n(X)$ is

a) positive definite (resp., negative definite) if $p = n$ (resp., $q = n$);
b) indefinite if $p \neq 0$ and $q \neq 0$;
c) nonnegative (resp., nonpositive) if $q = 0$, $p < n$ (resp., $p = 0$, $q < n$).

THEOREM. *For any real symmetric quadratic form $A_n(X)$ there exists a real orthogonal transformation (M5.4.1.3), whose matrix B possesses the property $B^T B = BB^T = I$, that reduces the quadratic form to the canonical form (M5.4.2.1). The canonical coefficients $\lambda_1, \ldots, \lambda_n$ are eigenvalues of the quadratic form matrix A.*

► **Lagrange's method of reduction of a quadratic form to a canonical form.** For the canonical form (M5.4.1.1), consider the following two cases.

Case 1. Suppose that $a_{mm} \neq 0$ for some m $(1 \leq m \leq n)$. By letting

$$A_n(X) = \frac{1}{a_{mm}} \left(\sum_{k=1}^{n} a_{mk} x_k \right)^2 + A_{n-1}(X), \qquad \text{(M5.4.2.2)}$$

one can easily verify that the quadratic form $A_{n-1}(X)$ does not contain the variable x_m (it contains $n-1$ variables or fewer). This method of isolating a perfect square in a quadratic form can always be applied if the matrix $[a_{ij}]$ $(i, j = 1, 2, \ldots, n)$ contains nonzero diagonal elements.

Case 2. Suppose that $a_{mm} = a_{ss} = 0$, but $a_{ms} \neq 0$. In this case, the quadratic form can be represented as

$$A_n(X) = \frac{1}{2a_{ms}} \left[\sum_{k=1}^{n} (a_{mk} + a_{sk}) x_k \right]^2 - \frac{1}{2a_{ms}} \left[\sum_{k=1}^{n} (a_{mk} - a_{sk}) x_k \right]^2 + A_{n-2}(X), \qquad \text{(M5.4.2.3)}$$

where $A_{n-2}(X)$ does not contain the variables x_m and x_s (it contains $n-2$ variables), and the linear forms in square brackets are linearly independent (and therefore can be taken as new independent variables or coordinates).

By combining the above two procedures, the quadratic form $A_n(X)$ can always be represented in terms of squared linear forms; these forms are linearly independent, since each contains a variable which is absent from the other linear forms. By taking the linear forms to be new independent variables, one obtains the canonical representation of the quadratic form (M5.4.2.1).

Note that the main formulas (M5.4.2.2) and (M5.4.2.3) can be rewritten as

$$A_n(X) = \frac{1}{4a_{mm}}\left(\frac{\partial A_n}{\partial x_m}\right)^2 + A_{n-1}(X), \qquad \text{(M5.4.2.2}a\text{)}$$

$$A_n(X) = \frac{1}{8a_{ms}}\left[\left(\frac{\partial A_n}{\partial x_m} + \frac{\partial A_n}{\partial x_s}\right)^2 - \left(\frac{\partial A_n}{\partial x_m} - \frac{\partial A_n}{\partial x_s}\right)^2\right] + A_{n-2}(X). \qquad \text{(M5.4.2.3}a\text{)}$$

Example. Reduce the quadratic form

$$A_3(X) = 4x_1^2 + x_2^2 + x_3^2 - 4x_1x_2 - 4x_1x_3 + 4x_2x_3$$

to a canonical form.

Using formula (M5.4.2.2a) with $m=1$, we get

$$A_3(X) = \tfrac{1}{16}(8x_1 - 4x_2 - 4x_3)^2 + 2x_2x_3 = (2x_1 - x_2 - x_3)^2 + A_2(X).$$

Further applying formula (M5.4.2.3a) with $m=2$ and $s=3$ to $A_2(X) = 2x_2x_3$, we obtain

$$A_2(X) = 2x_2x_3 = \tfrac{1}{8}(2x_2 + 2x_3)^2 - \tfrac{1}{8}(2x_3 - 2x_2)^2 = \tfrac{1}{2}(x_2 + x_3)^2 - \tfrac{1}{2}(x_2 - x_3)^2.$$

The two formulas just obtained yield a canonical representation of the original form:

$$A_3(X) = y_1^2 + \tfrac{1}{2}y_2^2 - \tfrac{1}{2}y_3^2,$$

where

$$y_1 = 2x_1 - x_2 - x_3, \qquad y_2 = x_2 + x_3, \qquad y_3 = x_2 - x_3.$$

► **Jacobi's formula.** Introduce the following notation:

$$A\begin{pmatrix} x_1 & x_2 & \dots & x_k \\ y_1 & y_2 & \dots & y_k \end{pmatrix} = \sum_{i,j=1}^{k} a_{ij}x_ix_j$$

Let

$$D_k = A\begin{pmatrix} 1 & 2 & \dots & k \\ 1 & 2 & \dots & k \end{pmatrix} \neq 0 \qquad (k = 1,\, 2,\, \dots,\, r),$$

where r is the rank of the quadratic form (M5.4.1.1). Then the form (M5.4.1.1) admits the canonical representation

$$A_n(X) = \frac{1}{a_{11}}\,y_1^2 + \sum_{k=2}^{r} \frac{1}{D_{k-1}D_k}\,y_k^2,$$

where

$$y_k = c_{kk}x_k + c_{k,k+1}x_{k+1} + \dots + c_{kn}x_n, \quad c_{kq} = A\begin{pmatrix} 1 & 2 & \dots & k-1 & k \\ 1 & 2 & \dots & k-1 & q \end{pmatrix};$$
$$k = 1,\, 2,\, \dots,\, r; \quad q = k,\, k+1,\, \dots,\, n.$$

► **Normal representation of a real quadratic form.** Any real quadratic form (M5.4.1.1) admits the *normal representation*

$$A_n(X)=\sum_{i=1}^{n}\varepsilon_i z_i^2,$$

where $z_1, \dots, z_n$ are the new variables and $\varepsilon_1, \dots, \varepsilon_n$ are coefficients taking the values $-1, 0, 1$.

A normal representation can be obtained by the following transformations:

1. One obtains the canonical representation (M5.4.2.1), for example, by Lagrange's method.
2. With the nondegenerate coordinate transformation

$$y_i=\begin{cases}\dfrac{1}{\sqrt{\lambda_i}}\,z_i & \text{for } \lambda_i>0,\\[2mm] \dfrac{1}{\sqrt{-\lambda_i}}\,z_i & \text{for } \lambda_i<0,\\[2mm] z_i & \text{for } \lambda_i=0,\end{cases}$$

the canonical representation can be converted to a normal representation.

► **Simultaneous reduction of two quadratic forms to sums of squares.**

THEOREM. *Let $A_n(X)$ and $B_n(X)$ be real symmetric quadratic forms in n variables and let $B_n(X)$ be positive definite. Then there exists a real transformation (M5.4.1.3) that reduces the two forms to*

$$A(X)=\sum_{k=1}^{n}\lambda_k y_k^2,\qquad B(X)=\sum_{k=1}^{n}y_k^2,$$

where y_k are new variables. The set of real $\lambda_1, \dots, \lambda_n$ coincides with the spectrum of eigenvalues of the matrix $B^{-1}A$; this set consists of the roots of the algebraic equation

$$\det(A-\lambda B)=0.$$

M5.5. Linear Spaces

M5.5.1. Concept of a Linear Space. Its Basis and Dimension

► **Definition of a linear space.** A *linear space* or a *vector space* over a field of *scalars* (usually, the field of real numbers or the field of complex numbers) is a set $\mathcal{V}$ of elements $\mathbf{x}, \mathbf{y}, \mathbf{z}, \dots$ (also called *vectors*) of any nature for which the following conditions hold:

I. There is a rule that establishes correspondence between any pair of elements $\mathbf{x}, \mathbf{y} \in \mathcal{V}$ and a third element $\mathbf{z} \in \mathcal{V}$, called the *sum* of the elements $\mathbf{x}, \mathbf{y}$ and denoted by $\mathbf{z}=\mathbf{x}+\mathbf{y}$.

II. There is a rule that establishes correspondence between any pair $\mathbf{x}$, λ, where $\mathbf{x}$ is an element of $\mathcal{V}$ and λ is a scalar, and an element $\mathbf{u} \in \mathcal{V}$, called the *product of a scalar λ and a vector* $\mathbf{x}$ and denoted by $\mathbf{u}=\lambda\mathbf{x}$.

III. The following eight axioms are assumed for the above two operations:

   1. Commutativity of the sum: $\mathbf{x}+\mathbf{y}=\mathbf{y}+\mathbf{x}$.
   2. Associativity of the sum: $(\mathbf{x}+\mathbf{y})+\mathbf{z}=\mathbf{x}+(\mathbf{y}+\mathbf{z})$.
   3. There is a zero element 0 such that $\mathbf{x}+0=\mathbf{x}$ for any $\mathbf{x}$.

4. For any element $\mathbf{x}$ there is an opposite element $\mathbf{x}'$ such that $\mathbf{x} + \mathbf{x}' = 0$.
5. A special role of the unit scalar 1: $1 \cdot \mathbf{x} = \mathbf{x}$ for any element $\mathbf{x}$.
6. Associativity of the multiplication by scalars: $\lambda(\mu\mathbf{x}) = (\lambda\mu)\mathbf{x}$.
7. Distributivity with respect to the addition of scalars: $(\lambda + \mu)\mathbf{x} = \lambda\mathbf{x} + \mu\mathbf{x}$.
8. Distributivity with respect to a sum of vectors: $\lambda(\mathbf{x} + \mathbf{y}) = \lambda\mathbf{x} + \lambda\mathbf{y}$.

This is the definition of an abstract linear space. We obtain a *specific linear space* if the nature of the elements and the operations of addition and multiplication by scalars are concretized.

Example 1. Consider the set of all free vectors in three-dimensional space. If addition of these vectors and their multiplication by scalars are defined as in analytic geometry (see Subsection M4.5.1), this set becomes a linear space denoted by B_3.

Example 2. Consider the *n-dimensional coordinate space* $\mathbb{R}^n$, whose elements are ordered sets of n arbitrary real numbers $(x_1, \dots, x_n)$. The generic element of this space is denoted by $\mathbf{x}$, i.e., $\mathbf{x} = (x_1, \dots, x_n)$, and the reals $x_1, \dots, x_n$ are called the *coordinates* of the element $\mathbf{x}$. From the algebraic standpoint, the set $\mathbb{R}^n$ may be regarded as the set of all row vectors with n real components.

The operations of addition of elements of $\mathbb{R}^n$ and their multiplication by scalars are defined by the following rules:

$$(x_1, \dots, x_n) + (y_1, \dots, y_n) = (x_1 + y_1, \dots, x_n + y_n),$$
$$\lambda(x_1, \dots, x_n) = (\lambda x_1, \dots, \lambda x_n).$$

Remark. If the field of scalars λ, μ, … in the above definition is the field of all real numbers, the corresponding linear spaces are called *real linear spaces*. If the field of scalars is that of all complex numbers, the corresponding space is called a *complex linear space*. In many situations, it is clear from the context which field of scalars is meant.

The above axioms imply the following properties of an arbitrary linear space:

1. The zero vector is unique, and for any element $\mathbf{x}$ the opposite element is unique.
2. The zero vector 0 is equal to the product of any element $\mathbf{x}$ by the scalar 0.
3. For any element $\mathbf{x}$, the opposite element is equal to the product of $\mathbf{x}$ by the scalar –1.
4. The *difference* of two elements $\mathbf{x}$ and $\mathbf{y}$, i.e., the element $\mathbf{z}$ such that $\mathbf{z} + \mathbf{y} = \mathbf{x}$, is unique.

► **Basis and dimension of a linear space. Isomorphism of linear spaces.** An element $\mathbf{y}$ is called a *linear combination* of elements $\mathbf{x}_1, \dots, \mathbf{x}_k$ of a linear space $\mathcal{V}$ if there exist scalars $\alpha_1, \dots, \alpha_k$ such that

$$\mathbf{y} = \alpha_1\mathbf{x}_1 + \cdots + \alpha_k\mathbf{x}_k.$$

Elements $\mathbf{x}_1, \dots, \mathbf{x}_k$ of the space $\mathcal{V}$ are said to be *linearly dependent* if there exist scalars $\alpha_1, \dots, \alpha_k$ such that $|\alpha_1|^2 + \cdots + |\alpha_k|^2 \neq 0$ and

$$\alpha_1\mathbf{x}_1 + \cdots + \alpha_k\mathbf{x}_k = 0,$$

where 0 is the zero element of $\mathcal{V}$.

Elements $\mathbf{x}_1, \dots, \mathbf{x}_k$ of the space $\mathcal{V}$ are said to be *linearly independent* if for any scalars $\alpha_1, \dots, \alpha_k$ such that $|\alpha_1|^2 + \cdots + |\alpha_k|^2 \neq 0$, we have

$$\alpha_1\mathbf{x}_1 + \cdots + \alpha_k\mathbf{x}_k \neq 0.$$

Remark 1. Elements $\mathbf{x}_1, \dots, \mathbf{x}_k$ of a linear space $\mathcal{V}$ are linearly dependent if and only if at least one of them is a linear combination of the others.

Remark 2. If at least one of the elements $\mathbf{x}_1, \dots, \mathbf{x}_k$ is equal to zero, then these elements are linearly dependent. If some of the elements $\mathbf{x}_1, \dots, \mathbf{x}_k$ are linearly dependent, then all these elements are linearly dependent.

Example 3. The elements $\mathbf{i}_1 = (1, 0, \ldots, 0)$, $\mathbf{i}_2 = (0, 1, \ldots, 0)$, …, $\mathbf{i}_n = (0, 0, \ldots, 1)$ of the space $\mathbb{R}^n$ (see Example 2) are linearly independent. For any $\mathbf{x} = (x_1, \ldots, x_n) \in \mathbb{R}^n$, the vectors $\mathbf{x}$, $\mathbf{i}_1, \ldots, \mathbf{i}_n$ are linearly dependent.

A *basis* of a linear space $\mathcal{V}$ is defined as any system of linearly independent vectors $\mathbf{e}_1, \ldots, \mathbf{e}_n$ such that for any element $\mathbf{x}$ of the space $\mathcal{V}$ there exist scalars $x_1, \ldots, x_n$ such that

$$\mathbf{x} = x_1\mathbf{e}_1 + \cdots + x_n\mathbf{e}_n.$$

This relation is called the *representation of an element* $\mathbf{x}$ *in terms of the basis* $\mathbf{e}_1, \ldots, \mathbf{e}_n$, and the scalars $x_1, \ldots, x_n$ are called the *coordinates* of the element $\mathbf{x}$ in that basis.

UNIQUENESS THEOREM. *The representation of any element* $\mathbf{x} \in \mathcal{V}$ *in terms of a given basis* $\mathbf{e}_1, \ldots, \mathbf{e}_n$ *is unique.*

Let $\mathbf{e}_1, \ldots, \mathbf{e}_n$ be any basis in $\mathcal{V}$ and vectors $\mathbf{x}$ and $\mathbf{y}$ have the coordinates $x_1, \ldots, x_n$ and $y_1, \ldots, y_n$ in that basis. Then the coordinates of the vector $\mathbf{x} + \mathbf{y}$ in that basis are $x_1 + y_1$, …, $x_n + y_n$, and the coordinates of the vector $\lambda\mathbf{x}$ are $\lambda x_1, \ldots, \lambda x_n$ for any scalar λ.

Example 4. Any three noncoplanar vectors form a basis in the linear space B_3 of all free vectors. The n elements $\mathbf{i}_1 = (1, 0, \ldots, 0)$, $\mathbf{i}_2 = (0, 1, \ldots, 0)$, …, $\mathbf{i}_n = (0, 0, \ldots, 1)$ form a basis in the linear space $\mathbb{R}^n$.

A linear space $\mathcal{V}$ is said to be n-*dimensional* if it contains n linearly independent elements and any $n + 1$ elements are linearly dependent. The number n is called the *dimension* of that space, $n = \dim \mathcal{V}$.

A linear space $\mathcal{V}$ is said to be *infinite-dimensional* ($\dim \mathcal{V} = \infty$) if for any positive integer N it contains N linearly independent elements.

THEOREM 1. *If* $\mathcal{V}$ *is a linear space of dimension* n*, then any* n *linearly independent elements of that space form its basis.*

THEOREM 2. *If a linear space* $\mathcal{V}$ *has a basis consisting of* n *elements, then* $\dim \mathcal{V} = n$.

Example 5. The dimension of the space B_3 of all free vectors is equal to 3. The dimension of the space $\mathbb{R}^n$ is equal to n.

Two linear spaces $\mathcal{V}$ and $\mathcal{V}'$ over the same field of scalars are said to be *isomorphic* if there is a one-to-one correspondence between the elements of these spaces such that if elements $\mathbf{x}$ and $\mathbf{y}$ from $\mathcal{V}$ correspond to elements $\mathbf{x}'$ and $\mathbf{y}'$ from $\mathcal{V}'$, then the element $\mathbf{x} + \mathbf{y}$ corresponds to $\mathbf{x}' + \mathbf{y}'$ and the element $\lambda\mathbf{x}$ corresponds to $\lambda\mathbf{x}'$ for any scalar λ.

Remark. If linear spaces $\mathcal{V}$ and $\mathcal{V}'$ are isomorphic, then the zero element of one space corresponds to the zero element of the other.

THEOREM. *Any two* n*-dimensional real (or complex) spaces* $\mathcal{V}$ *and* $\mathcal{V}'$ *are isomorphic.*

► **Affine space.** An *affine space* is a nonempty set $\mathcal{A}$ that consists of elements of any nature, called *points*, for which the following conditions hold:

I. There is a given linear (vector) space $\mathcal{V}$, called the *associated linear space*.

II. There is a rule by which any ordered pair of points $A, B \in \mathcal{A}$ is associated with an element (vector) from $\mathcal{V}$; this vector is denoted by $\overrightarrow{AB}$ and is called the *vector issuing from the point* A *with endpoint at* B.

III. The following conditions (called *axioms of affine space*) hold:
   1. For any point $A \in \mathcal{A}$ and any vector $\mathbf{a} \in \mathcal{V}$, there is a unique point $B \in \mathcal{A}$ such that $\overrightarrow{AB} = \mathbf{a}$.
   2. $\overrightarrow{AB} + \overrightarrow{BC} = \overrightarrow{AC}$ for any three points $A, B, C \in \mathcal{A}$.

By definition, the *dimension of an affine space* $\mathcal{A}$ is the dimension of the associated linear space $\mathcal{V}$, $\dim \mathcal{A} = \dim \mathcal{V}$.

Any linear space may be regarded as an affine space.

In particular, the space $\mathbb{R}^n$ can be naturally considered as an affine space. Thus if $A = (a_1, \ldots, a_n)$ and $B = (b_1, \ldots, b_n)$ are points of the affine space $\mathbb{R}^n$, then the corresponding vector $\overrightarrow{AB}$ from the linear space $\mathbb{R}^n$ is defined by $\overrightarrow{AB} = (b_1 - a_1, \ldots, b_n - a_n)$.

Let $\mathcal{A}$ be an n-dimensional affine space with the associated linear space $\mathcal{V}$. A *coordinate system* in the affine space $\mathcal{A}$ is a fixed point $O \in \mathcal{A}$, together with a fixed basis $\mathbf{e}_1, \ldots, \mathbf{e}_n \in \mathcal{V}$. The point O is called the *origin* of this coordinate system.

Let M be a point of an affine space $\mathcal{A}$ with a coordinate system $O\mathbf{e}_1 \ldots \mathbf{e}_n$. One says that the point M has *affine coordinates* (or simply coordinates) $x_1, \ldots, x_n$ in this coordinate system, and one writes $M = (x_1, \ldots, x_n)$ if $x_1, \ldots x_n$ are the coordinates of the radius-vector $\overrightarrow{OM}$ in the basis $\mathbf{e}_1, \ldots, \mathbf{e}_n$, i.e., $\overrightarrow{OM} = x_1\mathbf{e}_1 + \cdots + x_n\mathbf{e}_n$.

M5.5.2. Subspaces of Linear Spaces

► **Concept of a linear subspace and a linear span.** A subset $\mathcal{L}$ of a linear space $\mathcal{V}$ is called a *linear subspace* of $\mathcal{V}$ if the following conditions hold:

1. If $\mathbf{x}$ and $\mathbf{y}$ belong to $\mathcal{L}$, then the sum $\mathbf{x} + \mathbf{y}$ belongs to $\mathcal{L}$.
2. If $\mathbf{x}$ belongs to $\mathcal{L}$ and λ is an arbitrary scalar, then the element $\lambda\mathbf{x}$ belongs to $\mathcal{L}$.

The *null subspace* in a linear space $\mathcal{V}$ is its subset consisting of the single element zero. The space $\mathcal{V}$ itself can be regarded as its own subspace. These two subspaces are called *improper subspaces*. All other subspaces are called *proper subspaces*.

Example 1. A subset B_2 consisting of all free vectors parallel to a given plane is a subspace in the linear space B_3 of all free vectors.

The *linear span* $L(\mathbf{x}_1, \ldots, \mathbf{x}_m)$ of vectors $\mathbf{x}_1, \ldots, \mathbf{x}_m$ in a linear space $\mathcal{V}$ is, by definition, the set of all linear combinations of these vectors, i.e., the set of all vectors of the form

$$\alpha_1\mathbf{x}_1 + \cdots + \alpha_m\mathbf{x}_m,$$

where $\alpha_1, \ldots, \alpha_m$ are arbitrary scalars. The linear span $L(\mathbf{x}_1, \ldots, \mathbf{x}_m)$ is the least subspace of $\mathcal{V}$ containing the elements $\mathbf{x}_1, \ldots, \mathbf{x}_m$.

If a subspace $\mathcal{L}$ of an n-dimensional space $\mathcal{V}$ does not coincide with $\mathcal{V}$, then $\dim\mathcal{L} < n = \dim\mathcal{V}$.

Let elements $\mathbf{e}_1, \ldots, \mathbf{e}_k$ form a basis in a k-dimensional subspace of an n-dimensional linear space $\mathcal{V}$. Then this basis can be supplemented by elements $\mathbf{e}_{k+1}, \ldots, \mathbf{e}_n$ of the space $\mathcal{V}$, so that the system $\mathbf{e}_1, \ldots, \mathbf{e}_k, \mathbf{e}_{k+1}, \ldots, \mathbf{e}_n$ forms a basis in the space $\mathcal{V}$.

THEOREM ON THE DIMENSION OF A LINEAR SPAN. *The dimension of a linear span $L(\mathbf{x}_1, \ldots, \mathbf{x}_m)$ of elements $\mathbf{x}_1, \ldots, \mathbf{x}_m$ is equal to the maximal number of linearly independent vectors in the system $\mathbf{x}_1, \ldots, \mathbf{x}_m$.*

► **Sum and intersection of subspaces.** The *intersection* of subspaces $\mathcal{L}_1$ and $\mathcal{L}_2$ of one and the same linear space $\mathcal{V}$ is, by definition, the set of all elements $\mathbf{x}$ of $\mathcal{V}$ that belong simultaneously to both spaces $\mathcal{L}_1$ and $\mathcal{L}_2$. Such elements form a subspace of $\mathcal{V}$.

The *sum* of subspaces $\mathcal{L}_1$ and $\mathcal{L}_2$ of one and the same linear space $\mathcal{V}$ is, by definition, the set of all elements of $\mathcal{V}$ that can be represented in the form $\mathbf{y} + \mathbf{z}$, where $\mathbf{y}$ is an element of $\mathcal{V}_1$ and $\mathbf{z}$ is an element of $\mathcal{L}_2$. The sum of subspaces is also a subspace of $\mathcal{V}$.

THEOREM. *The sum of dimensions of arbitrary subspaces $\mathcal{L}_1$ and $\mathcal{L}_2$ of a finite-dimensional space $\mathcal{V}$ is equal to the sum of the dimension of their intersection and the dimension of their sum.*

Example 2. Let B_3 be the linear space of all free vectors (in three-dimensional space). Denote by $\mathcal{L}_1$ the subspace of all free vectors parallel to the plane OXY, and by $\mathcal{L}_2$ the subspace of all free vectors parallel to the plane OXZ. Then the sum of the subspaces $\mathcal{L}_1$ and $\mathcal{L}_2$ coincides with B_3, and their intersection consists of all free vectors parallel to the axis OX.

The dimension of each space $\mathcal{L}_1$ and $\mathcal{L}_2$ is equal to two, the dimension of their sum is equal to three, and the dimension of their intersection is equal to unity.

M5.5.3. Coordinate Transformations Corresponding to Basis Transformations in a Linear Space

► **Basis transformation and its inverse.** Let $\mathbf{e}_1, \dots, \mathbf{e}_n$ and $\widetilde{\mathbf{e}}_1, \dots, \widetilde{\mathbf{e}}_n$ be two arbitrary bases of an n-dimensional linear space $\mathcal{V}$. Suppose that the elements $\widetilde{\mathbf{e}}_1, \dots, \widetilde{\mathbf{e}}_n$ are expressed via $\mathbf{e}_1, \dots, \mathbf{e}_n$ by the formulas

$$\begin{aligned}
\widetilde{\mathbf{e}}_1 &= a_{11}\mathbf{e}_1 + a_{12}\mathbf{e}_2 + \cdots + a_{1n}\mathbf{e}_n,\\
\widetilde{\mathbf{e}}_2 &= a_{21}\mathbf{e}_1 + a_{22}\mathbf{e}_2 + \cdots + a_{2n}\mathbf{e}_n,\\
&\dots\dots\dots\dots\dots\dots\dots\dots\\
\widetilde{\mathbf{e}}_n &= a_{n1}\mathbf{e}_1 + a_{n2}\mathbf{e}_2 + \cdots + a_{nn}\mathbf{e}_n.
\end{aligned}$$

Thus, the transition from the basis $\mathbf{e}_1, \dots, \mathbf{e}_n$ to the basis $\widetilde{\mathbf{e}}_1, \dots, \widetilde{\mathbf{e}}_n$ is determined by the matrix

$$A \equiv \begin{pmatrix} a_{11} & a_{12} & \cdots & a_{1n}\\ a_{21} & a_{22} & \cdots & a_{2n}\\ \vdots & \vdots & \ddots & \vdots\\ a_{n1} & a_{n2} & \cdots & a_{nn} \end{pmatrix}.$$

Note that $\det A \neq 0$, i.e., the matrix A is nondegenerate.

The transition from the basis $\widetilde{\mathbf{e}}_1, \dots, \widetilde{\mathbf{e}}_n$ to the basis $\mathbf{e}_1, \dots, \mathbf{e}_n$ is determined by the matrix $B \equiv [b_{ij}] = A^{-1}$. Thus, we can write

$$\widetilde{\mathbf{e}}_i = \sum_{j=1}^{n} a_{ij}\mathbf{e}_j, \qquad \mathbf{e}_k = \sum_{j=1}^{n} b_{kj}\widetilde{\mathbf{e}}_j \qquad (i,k = 1,\,2,\,\dots,\,n). \tag{M5.5.3.1}$$

► **Relations between coordinate transformations and basis transformations.** Suppose that in a linear n-dimensional space $\mathcal{V}$, the transition from its basis $\mathbf{e}_1, \dots, \mathbf{e}_n$ to another basis $\widetilde{\mathbf{e}}_1, \dots, \widetilde{\mathbf{e}}_n$ is determined by the matrix A (see above). Let $\mathbf{x}$ be any element of the space $\mathcal{V}$ with the coordinates $(x_1, \dots, x_n)$ in the basis $\mathbf{e}_1, \dots, \mathbf{e}_n$ and the coordinates $(\widetilde{x}_1, \dots, \widetilde{x}_n)$ in the basis $\widetilde{\mathbf{e}}_1, \dots, \widetilde{\mathbf{e}}_n$, i.e.,

$$\mathbf{x} = x_1\mathbf{e}_1 + \cdots + x_n\mathbf{e}_n = \widetilde{x}_1\widetilde{\mathbf{e}}_1 + \cdots + \widetilde{x}_n\widetilde{\mathbf{e}}_n.$$

Then using formulas (M5.5.3.1), we obtain the following relations between these coordinates:

$$x_j = \sum_{i=1}^{n} \widetilde{x}_i a_{ij}, \qquad \widetilde{x}_k = \sum_{l=1}^{n} x_l b_{lk}, \qquad j,k = 1,\dots,n.$$

In terms of matrices and row vectors, these relations can be written as follows:

$$(x_1,\dots,x_n) = (\widetilde{x}_1,\dots,\widetilde{x}_n)A, \qquad (\widetilde{x}_1,\dots,\widetilde{x}_n) = (x_1,\dots,x_n)A^{-1}$$

or, in terms of column vectors,

$$(x_1,\dots,x_n)^T = A^T(\widetilde{x}_1,\dots,\widetilde{x}_n)^T, \qquad (\widetilde{x}_1,\dots,\widetilde{x}_n)^T = (A^{-1})^T(x_1,\dots,x_n)^T,$$

where the superscript T indicates the transpose of a matrix.

M5.5.4. Euclidean Space

► **Definition and properties of a Euclidean space.** A *real Euclidean space* (or simply, *Euclidean space*) is a real linear space $\mathcal{V}$ endowed with a *scalar product* (also known as *inner product* and *dot product*), which is a real-valued function of two arguments $\mathbf{x} \in \mathcal{V}$, $\mathbf{y} \in \mathcal{V}$ denoted by $\mathbf{x}\cdot\mathbf{y}$, and satisfying the following conditions (axioms of the scalar product):

1. Symmetry: $\mathbf{x} \cdot \mathbf{y} = \mathbf{y} \cdot \mathbf{x}$.
2. Distributivity: $(\mathbf{x}_1 + \mathbf{x}_2) \cdot \mathbf{y} = \mathbf{x}_1 \cdot \mathbf{y} + \mathbf{x}_2 \cdot \mathbf{y}$.
3. Homogeneity: $(\lambda\mathbf{x}) \cdot \mathbf{y} = \lambda(\mathbf{x} \cdot \mathbf{y})$ for any real λ.
4. Positive definiteness: $\mathbf{x} \cdot \mathbf{x} \geq 0$ for any $\mathbf{x}$, and $\mathbf{x} \cdot \mathbf{x} = 0$ if and only if $\mathbf{x} = 0$.

Example 1. Consider the linear space B_3 of all free vectors in three-dimensional space. The space B_3 becomes a Euclidean space if the scalar product is introduced as in analytic geometry (see Subsection M4.5.3):

$$\mathbf{x} \cdot \mathbf{y} = |\mathbf{x}|\,|\mathbf{y}| \cos\varphi,$$

where φ is the angle between the vectors $\mathbf{x}$ and $\mathbf{y}$.

Example 2. Consider the n-dimensional coordinate space $\mathbb{R}^n$ whose elements are ordered systems of n arbitrary real numbers, $\mathbf{x} = (x_1, \dots, x_n)$. Endowing this space with the scalar product

$$\mathbf{x} \cdot \mathbf{y} = x_1y_1 + \cdots + x_ny_n,$$

we obtain a Euclidean space.

THEOREM. *For any two elements* $\mathbf{x}$ *and* $\mathbf{y}$ *of a Euclidean space, the Cauchy–Schwarz inequality holds:*

$$(\mathbf{x} \cdot \mathbf{y})^2 \leq (\mathbf{x} \cdot \mathbf{x})(\mathbf{y} \cdot \mathbf{y}).$$

Here equality holds if and only if one of the vectors is 0 *or one vector is a multiple of the other.*

A linear space $\mathcal{V}$ is called a *normed space* if it is endowed with a *norm*, which is a real-valued function of $\mathbf{x} \in \mathcal{V}$, denoted by $\|\mathbf{x}\|$ and satisfying the following conditions:

1. Homogeneity: $\|\lambda\mathbf{x}\| = |\lambda|\,\|\mathbf{x}\|$ for any real λ.
2. Positive definiteness: $\|\mathbf{x}\| \geq 0$ and $\|\mathbf{x}\| = 0$ if and only if $\mathbf{x} = 0$.
3. The *triangle inequality* (also called the *Minkowski inequality*) holds for all elements $\mathbf{x}$ and $\mathbf{y}$:

$$\|\mathbf{x} + \mathbf{y}\| \leq \|\mathbf{x}\| + \|\mathbf{y}\|. \tag{M5.5.4.1}$$

The value $\|\mathbf{x}\|$ is called the *norm of an element* $\mathbf{x}$ or its *length*.

THEOREM. *Any Euclidean space becomes a normed space if the norm is introduced by*

$$\|\mathbf{x}\| = \sqrt{\mathbf{x} \cdot \mathbf{x}}. \tag{M5.5.4.2}$$

COROLLARY. *In any Euclidean space with the norm (M5.5.4.2), the triangle inequality (M5.5.4.1) holds for all its elements* $\mathbf{x}$ *and* $\mathbf{y}$.

The *distance between elements* $\mathbf{x}$ and $\mathbf{y}$ of a Euclidean space is defined by

$$d(\mathbf{x}, \mathbf{y}) = \|\mathbf{x} - \mathbf{y}\|.$$

One says that φ is the *angle* between two elements $\mathbf{x}$ and $\mathbf{y}$ of a Euclidean space if

$$\cos\varphi = \frac{\mathbf{x} \cdot \mathbf{y}}{\|\mathbf{x}\|\,\|\mathbf{y}\|}.$$

Two elements $\mathbf{x}$ and $\mathbf{y}$ of a Euclidean space are said to be *orthogonal* if their scalar product is equal to zero, $\mathbf{x} \cdot \mathbf{y} = 0$.

PYTHAGOREAN THEOREM. *Let* $\mathbf{x}_1, \dots \mathbf{x}_m$ *be mutually orthogonal elements of a Euclidean space, i.e.,* $\mathbf{x}_i \cdot \mathbf{x}_j = 0$ *for* $i \neq j$. *Then*

$$\|\mathbf{x}_1 + \cdots + \mathbf{x}_m\|^2 = \|\mathbf{x}_1\|^2 + \cdots + \|\mathbf{x}_m\|^2.$$

Example 3. In the Euclidean space B_3 of free vectors with the usual scalar product (see Example 1), the following relations hold:

$$\|\mathbf{a}\| = |\mathbf{a}|, \quad (\mathbf{a}\cdot\mathbf{b})^2 \le |\mathbf{a}|^2|\mathbf{b}|^2, \quad |\mathbf{a}+\mathbf{b}| \le |\mathbf{a}| + |\mathbf{b}|.$$

In the Euclidean space $\mathbb{R}^n$ of ordered systems of n numbers with the scalar product defined in Example 2, the following relations hold:

$$\begin{aligned}
&\|\mathbf{x}\| = \sqrt{x_1^2 + \cdots + x_n^2},\\
&(x_1y_1 + \cdots + x_ny_n)^2 \le (x_1^2 + \cdots + x_n^2)(y_1^2 + \cdots + y_n^2),\\
&\sqrt{(x_1+y_1)^2 + \cdots + (x_n+y_n)^2} \le \sqrt{x_1^2 + \cdots + x_n^2} + \sqrt{y_1^2 + \cdots + y_n^2}.
\end{aligned}$$

► **Orthonormal basis in a finite-dimensional Euclidean space.** For elements $\mathbf{x}_1, \ldots, \mathbf{x}_m$ of a Euclidean space, the mth-order determinant $\det[\mathbf{x}_i\cdot\mathbf{x}_j]$ is called their *Gram determinant*. These elements are linearly independent if and only if their Gram determinant is different from zero.

One says that n elements $\mathbf{i}_1, \ldots, \mathbf{i}_n$ of an n-dimensional Euclidean space $\mathcal{V}$ form its *orthonormal basis* if these elements have unit norm and are mutually orthogonal, i.e.,

$$\mathbf{i}_i\cdot\mathbf{i}_j = \begin{cases} 1 & \text{for } i = j,\\ 0 & \text{for } i \ne j.\end{cases}$$

THEOREM. *In any n-dimensional Euclidean space $\mathcal{V}$, there exists an orthonormal basis.*

Orthogonalization of linearly independent elements:

Let $\mathbf{e}_1, \ldots, \mathbf{e}_n$ be n linearly independent vectors of an n-dimensional Euclidean space $\mathcal{V}$. From these vectors, one can construct an orthonormal basis of $\mathcal{V}$ using the following algorithm (called *Gram–Schmidt orthogonalization*):

$$\mathbf{i}_i = \frac{\mathbf{g}_i}{\sqrt{\mathbf{g}_i\cdot\mathbf{g}_i}}, \quad \text{where} \quad \mathbf{g}_i = \mathbf{e}_i - \sum_{j=1}^{i}(\mathbf{e}_i\cdot\mathbf{i}_j)\mathbf{i}_j \quad (i = 1, 2, \ldots, n). \qquad \text{(M5.5.4.3)}$$

Remark. In any n-dimensional ($n > 1$) Euclidean space $\mathcal{V}$, there exist infinitely many orthonormal bases.

Properties of an orthonormal basis of a Euclidean space:

1. Let $\mathbf{i}_1, \ldots, \mathbf{i}_n$ be an orthonormal basis of a Euclidean space $\mathcal{V}$. Then the scalar product of two elements $\mathbf{x} = x_1\mathbf{i}_1 + \cdots + x_n\mathbf{i}_n$ and $\mathbf{y} = y_1\mathbf{i}_1 + \cdots + y_n\mathbf{i}_n$ is equal to the sum of products of their respective coordinates:
$$\mathbf{x}\cdot\mathbf{y} = x_1y_1 + \cdots + x_ny_n.$$
2. The coordinates of any vector $\mathbf{x}$ in an orthonormal basis $\mathbf{i}_1, \ldots, \mathbf{i}_n$ are equal to the scalar product of $\mathbf{x}$ and the corresponding vector of the basis (or the projection of the element $\mathbf{x}$ on the axis in the direction of the corresponding vector of the basis):
$$x_k = \mathbf{x}\cdot\mathbf{i}_k \quad (k = 1, 2, \ldots, n).$$

Remark. In an arbitrary basis $\mathbf{e}_1, \ldots, \mathbf{e_n}$ of a Euclidean space, the scalar product of two elements $\mathbf{x} = x_1\mathbf{e}_1 + \cdots + x_n\mathbf{e}_n$ and $\mathbf{y} = y_1\mathbf{e}_1 + \cdots + y_n\mathbf{e}_n$ has the form

$$\mathbf{x}\cdot\mathbf{y} = \sum_{i=1}^{n}\sum_{j=1}^{n} a_{ij}x_iy_j,$$

where $a_{ij} = \mathbf{e}_i\cdot\mathbf{e}_j$ $(i, j = 1, 2, \ldots, n)$.

Two Euclidean spaces $\mathcal{V}$ and $\widetilde{\mathcal{V}}$ are said to be *isomorphic* if one can establish a one-to-one correspondence between the elements of these spaces satisfying the following conditions: if elements $\mathbf{x}$ and $\mathbf{y}$ of $\mathcal{V}$ correspond to elements $\widetilde{\mathbf{x}}$ and $\widetilde{\mathbf{y}}$ of $\widetilde{\mathcal{V}}$, then the element $\mathbf{x}+\mathbf{y}$ corresponds to $\widetilde{\mathbf{x}}+\widetilde{\mathbf{y}}$; the element $\lambda\mathbf{x}$ corresponds to $\lambda\widetilde{\mathbf{x}}$ for any λ; the scalar product $(\mathbf{x}\cdot\mathbf{y})_{\mathcal{V}}$ is equal to the scalar product $(\widetilde{\mathbf{x}}\cdot\widetilde{\mathbf{y}})_{\widetilde{\mathcal{V}}}$.

THEOREM. *Any two n-dimensional Euclidean spaces $\mathcal{V}$ and $\widetilde{\mathcal{V}}$ are isomorphic.*

Chapter M6

Limits and Derivatives

M6.1. Basic Concepts of Mathematical Analysis

M6.1.1. Number Sets. Functions of Real Variable

► **Real axis, intervals, and segments.** The *real axis* is a straight line with a point O chosen as the origin, a positive direction, and a scale unit.

There is a one-to-one correspondence between the set of all real numbers $\mathbb{R}$ and the set of all points of the real axis, with each real x being represented by a point on the real axis separated from O by the distance $|x|$ and lying to the right of O for $x > 0$, or to the left of O for $x < 0$.

One often has to deal with the following number sets (sets of real numbers or sets on the real axis).

1. Sets of the form (a, b), $(-\infty, b)$, $(a, +\infty)$, and $(-\infty, +\infty)$ consisting, respectively, of all $x \in \mathbb{R}$ such that $a < x < b$, $x < b$, $x > a$, and x is arbitrary are called *open intervals* (sometimes simply *intervals*).

2. Sets of the form $[a, b]$ consisting of all $x \in \mathbb{R}$ such that $a \le x \le b$ are called *closed intervals* or *segments*.

3. Sets of the form $(a, b]$, $[a, b)$, $(-\infty, b]$, $[a, +\infty)$ consisting of all x such that $a < x \le b$, $a \le x < b$, $x \le b$, $x \ge a$ are called *half-open intervals*.

A *neighborhood of a point* $x_0 \in \mathbb{R}$ is defined as any open interval (a, b) containing x_0 ($a < x_0 < b$). A neighborhood of the "point" $+\infty$, $-\infty$, or ∞ is defined, respectively, as any set of the form $(b, +\infty)$, $(-\infty, c)$ or $(-\infty, -a) \cup (a, +\infty)$ (here, $a \ge 0$).

► **Lower and upper bound of a set on a straight line.** The *upper bound* of a set of real numbers is the least number that bounds the set from above. The *lower bound* of a set of real numbers is the largest number that bounds the set from below.

In more details: let a set of real numbers $X \in \mathbb{R}$ be given. A number β is called its upper bound and denoted $\sup X$ if for any $x \in X$ the inequality $x \le \beta$ holds and for any $\beta_1 < \beta$ there exists an $x_1 \in X$ such that $x_1 > \beta_1$. A number α is called the lower bound of X and denoted $\inf X$ if for any $x \in X$ the inequality $x \ge \alpha$ holds and for any $\alpha_1 > \alpha$ there exists an $x_1 \in X$ such that $x_1 < \alpha_1$.

Example 1. For a set X consisting of two numbers a and b ($a < b$), we have

$$\inf X = a, \qquad \sup X = b.$$

Example 2. For intervals (open, closed, and half-open), we have

$$\inf(a, b) = \inf[a, b] = \inf(a, b] = \inf[a, b) = a,$$
$$\sup(a, b) = \sup[a, b] = \sup(a, b] = \sup[a, b) = b.$$

One can see that the upper and lower bounds may belong to a given set (e.g., for closed intervals) and may not (e.g., for open intervals).

The symbol $+\infty$ (resp., $-\infty$) is called the upper (resp., lower) bound of a set unbounded from above (resp., from below).

► Real-valued functions of real variable. Methods of defining a function.

1°. Let D and E be two sets of real numbers. Suppose that there is a relation between the points of D and E such that to each $x \in D$ there corresponds some $y \in E$, denoted by $y = f(x)$. In this case, one speaks of a *function* f defined on the set D and taking its values in the set E. The set D is called the *domain of the function* f, and the subset of E consisting of all elements $f(x)$ is called the *range of the function* f. This functional relation is often denoted by $y = f(x)$, $f : D \to E$, $f : x \mapsto y$.

The following terms are also used: x is the *independent variable* or the *argument*; y is the *dependent variable*.

2°. The most common and convenient way to define a function is the *analytic method*: the function is defined explicitly by means of a formula (or several formulas) depending on the argument x; for instance, $y = 2\sin x + 1$.

Implicit definition of a function consists of using an equation of the form $F(x, y) = 0$, from which one calculates the value y for any fixed value of the argument x.

Parametric definition of a function consists of defining the values of the independent variable x and the dependent variable y by a pair of formulas depending on an auxiliary variable t (parameter): $x = p(t)$, $y = q(t)$.

Quite often functions are defined in terms of convergent series or by means of tables or graphs. There are some other methods of defining functions.

3°. The *graph of a function* is the representation of a function $y = f(x)$ as a line on the plane with orthogonal coordinates x, y, the points of the line having the coordinates x, $y = f(x)$, where x is an arbitrary point from the domain of the function.

► Single-valued, periodic, odd and even functions.

1°. A function is *single-valued* if each value of its argument corresponds to a unique value of the function. A function is *multi-valued* if there is at least one value of its argument corresponding to two or more values of the function. In what follows, we consider only single-valued functions, unless indicated otherwise.

2°. A function $f(x)$ is called *periodic* with period T (or T-*periodic*) if $f(x + T) = f(x)$ for any x.

3°. A function $f(x)$ is called *even* if it satisfies the condition $f(x) = f(-x)$ for any x. A function $f(x)$ is called *odd* if it satisfies the condition $f(x) = -f(-x)$ for any x.

► Decreasing, increasing, monotone, and bounded functions.

1°. A function $f(x)$ is called *increasing or strictly increasing* (resp., *nondecreasing*) on a set $D \subset \mathbb{R}$ if for any $x_1, x_2 \in D$ such that $x_1 > x_2$, we have $f(x_1) > f(x_2)$ (resp., $f(x_1) \geq f(x_2)$). A function $f(x)$ is called *decreasing or strictly decreasing* (resp., *nonincreasing*) on a set D if for all $x_1, x_2 \in D$ such that $x_1 > x_2$, we have $f(x_1) < f(x_2)$ (resp., $f(x_1) \leq f(x_2)$). All such functions are called *monotone functions*. Strictly increasing or decreasing functions are called *strictly monotone*.

2°. A function $f(x)$ is called *bounded* on a set D if $|f(x)| < M$ for all $x \in D$, where M is a finite constant. A function $f(x)$ is called *bounded from above* (*bounded from below*) on a set D if $f(x) < M$ $(M < f(x))$ for all $x \in D$, where M is a real constant.

► Composite and inverse functions.

1°. Consider a function $u = u(x)$, $x \in D$, with values $u \in E$, and let $y = f(u)$ be a function defined on E. Then the function $y = f\big(u(x)\big)$, $x \in D$, is called a *composite function* or the *superposition* of the functions f and u.

2°. Consider a function $y = f(x)$ that maps $x \in D$ into $y \in E$. The *inverse function* of $y = f(x)$ is a function $x = g(y)$ defined on E and such that $x = g(f(x))$ for all $x \in D$. The inverse function is often denoted by $g = f^{-1}$.

For strictly monotone functions $f(x)$, the inverse function always exists. In order to construct the inverse function $g(y)$, one should use the relation $y = f(x)$ to express x through y. The function $g(y)$ is monotonically increasing or decreasing together with $f(x)$.

M6.1.2. Limit of a Sequence

► **Some definitions.** Suppose that there is a correspondence between each positive integer n and some (real or complex) number denoted, for instance, by x_n. In this case, one says that a *numerical sequence* (or, simply, a *sequence*) $x_1, x_2, \dots, x_n, \dots$ is defined. Such a sequence is often denoted by $\{x_n\}$; x_n is called the *generic term* of the sequence.

Example 1. For the sequence $\{n^2 - 2\}$, we have $x_1 = -1$, $x_2 = 2$, $x_3 = 7$, $x_4 = 14$, etc.

A sequence is called *bounded* (bounded from above, bounded from below) if there is a constant M such that $|x_n| < M$ (respectively, $x_n < M$, $x_n > M$) for all $n = 1, 2, \dots$

► **Limit of a sequence.** A number b is called the *limit of a sequence* $x_1, x_2, \dots, x_n, \dots$ if for any $\varepsilon > 0$ there is $N = N(\varepsilon)$ such that $|x_n - b| < \varepsilon$ for all $n > N$.

If b is the limit of the sequence $\{x_n\}$, one writes $\lim\limits_{n\to\infty} x_n = b$ or $x_n \to b$ as $n \to \infty$.

The limit of a constant sequence $\{x_n = c\}$ exists and is equal to c, i.e., $\lim\limits_{n\to\infty} c = c$. In this case, the inequality $|x_n - c| < \varepsilon$ takes the form $0 < \varepsilon$ and holds for all n.

Example 2. Let us show that $\lim\limits_{n\to\infty} \dfrac{n}{n+1} = 1$.

Consider the difference $\left|\dfrac{n}{n+1} - 1\right| = \dfrac{1}{n+1}$. The inequality $\dfrac{1}{n+1} < \varepsilon$ holds for all $n > \dfrac{1}{\varepsilon} - 1 = N(\varepsilon)$. Therefore, for any positive ε there exists an $N = \dfrac{1}{\varepsilon} - 1$ such that for $n > N$ we have $\left|\dfrac{n}{n+1} - 1\right| < \varepsilon$.

It may happen that a sequence $\{x_n\}$ has no limit at all. For example, this is the case for the sequence $\{x_n\} = \{(-1)^n\}$. A sequence that has a finite limit is called *convergent*.

THEOREM (BOLZANO–CAUCHY). *A sequence x_n has a finite limit if and only if for any $\varepsilon > 0$, there is N such that the inequality*

$$|x_n - x_m| < \varepsilon$$

holds for all $n > N$ and $m > N$.

► **Properties of convergent sequences.**

1. Any convergent sequence can have only one limit.

2. Any convergent sequence is bounded. From any bounded sequence one can extract a convergent subsequence.*

3. If a sequence converges to b, then any of its subsequences also converges to b.

4. If $\{x_n\}$, $\{y_n\}$ are two convergent sequences, then the sequences $\{x_n \pm y_n\}$, $\{x_n \cdot y_n\}$, and $\{x_n/y_n\}$ (in this ratio, it is assumed that $y_n \neq 0$ and $\lim\limits_{n\to\infty} y_n \neq 0$) are also convergent

---

* Let $\{x_n\}$ be a given sequence and let $\{n_k\}$ be a strictly increasing sequence with k and n_k being natural numbers. The sequence $\{x_{n_k}\}$ is called a *subsequence* of the sequence $\{x_n\}$.

and

$$\begin{aligned}
&\lim_{n\to\infty}(x_n \pm y_n) = \lim_{n\to\infty} x_n \pm \lim_{n\to\infty} y_n;\\
&\lim_{n\to\infty}(cx_n) = c\lim_{n\to\infty} x_n \qquad (c = \text{const});\\
&\lim_{n\to\infty}(x_n \cdot y_n) = \lim_{n\to\infty} x_n \cdot \lim_{n\to\infty} y_n;\\
&\lim_{n\to\infty}\frac{x_n}{y_n} = \frac{\lim\limits_{n\to\infty} x_n}{\lim\limits_{n\to\infty} y_n}.
\end{aligned}$$

5. If $\{x_n\}$, $\{y_n\}$ are convergent sequences and the inequality $x_n \le y_n$ holds for all n, then $\lim\limits_{n\to\infty} x_n \le \lim\limits_{n\to\infty} y_n$.

6. If the inequalities $x_n \le y_n \le z_n$ hold for all n and $\lim\limits_{n\to\infty} x_n = \lim\limits_{n\to\infty} z_n = b$, then $\lim\limits_{n\to\infty} y_n = b$.

► **Increasing, decreasing, and monotone sequences.** A sequence $\{x_n\}$ is called *increasing or strictly increasing* (resp., *nondecreasing*) if the inequality $x_{n+1} > x_n$ (resp., $x_{n+1} \ge x_n$) holds for all n. A sequence $\{x_n\}$ is called *decreasing or strictly decreasing* (resp., *nonincreasing*) if the inequality $x_{n+1} < x_n$ (resp., $x_{n+1} \le x_n$) holds for all n. All such sequences are called *monotone sequences*. Strictly increasing or decreasing sequences are called *strictly monotone*.

THEOREM. *Any monotone bounded sequence has a finite limit.*

Example 3. It can be shown that the sequence $\left\{\left(1+\frac{1}{n}\right)^n\right\}$ is bounded and increasing. Therefore, it is convergent. Its limit is denoted by the letter e:

$$e = \lim_{n\to\infty}\left(1+\frac{1}{n}\right)^n \qquad (e \approx 2.71828).$$

Logarithms with the base e are called *natural* or *Napierian*, and $\log_e x$ is denoted by $\ln x$.

► **Properties of positive sequences.**

1°. If a sequence x_n ($x_n > 0$) has a limit (finite or infinite), then the sequence

$$y_n = \sqrt[n]{x_1 \cdot x_2 \ldots x_n}$$

has the same limit.

2°. From property 1° for the sequence

$$x_1,\ \frac{x_2}{x_1},\ \frac{x_3}{x_2},\ \ldots,\ \frac{x_n}{x_{n-1}},\ \frac{x_{n+1}}{x_n},\ \ldots,$$

we obtain a useful corollary

$$\lim_{n\to\infty}\sqrt[n]{x_n} = \lim_{n\to\infty}\frac{x_{n+1}}{x_n},$$

under the assumption that the second limit exists.

Example 4. Let us show that $\lim\limits_{n\to\infty} \dfrac{n}{\sqrt[n]{n!}} = e$.

Taking $x_n = \dfrac{n^n}{n!}$ and using property 2°, we get

$$\lim_{n\to\infty} \frac{n}{\sqrt[n]{n!}} = \lim_{n\to\infty} \frac{x_{n+1}}{x_n} = \lim_{n\to\infty} \left(1 + \frac{1}{n}\right)^n = e.$$

► **Infinitely small and infinitely large sequences.** A sequence x_n converging to zero is called *infinitely small* or *infinitesimal*.

A sequence x_n whose terms infinitely grow in absolute values with the growth of n is called *infinitely large* or "*tending to infinity*." In this case, the following notation is used: $\lim\limits_{n\to\infty} x_n = \infty$. If, in addition, all terms of the sequence starting from some number are positive (negative), then one says that the sequence x_n converges to "plus (minus) infinity," and one writes $\lim\limits_{n\to\infty} x_n = +\infty$ $\bigl(\lim\limits_{n\to\infty} x_n = -\infty\bigr)$. For instance, $\lim\limits_{n\to\infty} (-1)^n n^2 = \infty$, $\lim\limits_{n\to\infty} \sqrt{n} = +\infty$, $\lim\limits_{n\to\infty} (-n) = -\infty$.

THEOREM (STOLZ). *Let x_n and y_n be two infinitely large sequences, $y_n \to +\infty$, and y_n increases with the growth of n (at least for sufficiently large n): $y_{n+1} > y_n$. Then*

$$\lim_{n\to\infty} \frac{x_n}{y_n} = \lim_{n\to\infty} \frac{x_n - x_{n-1}}{y_n - y_{n-1}},$$

provided that the right limit exists (finite or infinite).

Example 5. Let us find the limit of the sequence

$$z_n = \frac{1^k + 2^k + \cdots + n^k}{n^{k+1}}.$$

Taking $x_n = 1^k + 2^k + \cdots + n^k$ and $y_n = n^{k+1}$ in the Stolz theorem, we get

$$\lim_{n\to\infty} z_n = \lim_{n\to\infty} \frac{n^k}{n^{k+1} - (n-1)^{k+1}}.$$

Since $(n-1)^{k+1} = n^{k+1} - (k+1)n^k + \cdots$, we have $n^{k+1} - (n-1)^{k+1} = (k+1)n^k + \cdots$, and therefore

$$\lim_{n\to\infty} z_n = \lim_{n\to\infty} \frac{n^k}{(k+1)n^k + \cdots} = \frac{1}{k+1}.$$

► **Upper and lower limits of a sequence.** The limit (finite or infinite) of a subsequence of a given sequence x_n is called a partial limit of x_n. In the set of all partial limits of any sequence of real numbers, there always exists the largest and the least (finite or infinite). The largest (resp., least) partial limit of a sequence is called its *upper* (resp., *lower*) *limit*. The upper and lower limits of a sequence x_n are denoted, respectively,

$$\varlimsup_{n\to\infty} x_n, \qquad \varliminf_{n\to\infty} x_n.$$

Example 6. The upper and lower limits of the sequence $x_n = (-1)^n$ are, respectively,

$$\varlimsup_{n\to\infty} x_n = 1, \qquad \varliminf_{n\to\infty} x_n = -1.$$

A sequence x_n has a limit (finite or infinite) if and only if its upper limit coincides with its lower limit:

$$\lim_{n\to\infty} x_n = \varlimsup_{n\to\infty} x_n = \varliminf_{n\to\infty} x_n.$$

M6.1.3. Limit of a Function. Asymptotes

► Definition of the limit of a function. One-sided limits.

1°. One says that b is the *limit of a function* $f(x)$ as x tends to a if for any $\varepsilon > 0$ there is $\delta = \delta(\varepsilon) > 0$ such that $|f(x) - b| < \varepsilon$ for all x such that $0 < |x - a| < \delta$.

Notation: $\lim\limits_{x\to a} f(x) = b$ or $f(x) \to b$ as $x \to a$.

One says that b is the limit of a function $f(x)$ as x tends to $+\infty$ if for any $\varepsilon > 0$ there is $N = N(\varepsilon) > 0$ such that $|f(x) - b| < \varepsilon$ for all $x > N$.

Notation: $\lim\limits_{x\to+\infty} f(x) = b$ or $f(x) \to b$ as $x \to +\infty$.

In a similar way, one defines the limits for $x \to -\infty$ or $x \to \infty$.

THEOREM (BOLZANO–CAUCHY 1). *A function $f(x)$ has a finite limit as x tends to a (a is assumed finite) if and only if for any $\varepsilon > 0$ there is $\delta > 0$ such that the inequality*

$$|f(x_1) - f(x_2)| < \varepsilon \qquad \text{(M6.1.3.1)}$$

holds for all x_1, x_2 such that $|x_1 - a| < \delta$ and $|x_2 - a| < \delta$.

THEOREM (BOLZANO–CAUCHY 2). *A function $f(x)$ has a finite limit as x tends to $+\infty$ if and only if for any $\varepsilon > 0$ there is $\Delta > 0$ such that the inequality (M6.1.3.1) holds for all $x_1 > \Delta$ and $x_2 > \Delta$.*

2°. One says that b is the *left-hand limit* (resp., *right-hand limit*) of a function $f(x)$ as x tends to a if for any $\varepsilon > 0$ there is $\delta = \delta(\varepsilon) > 0$ such that $|f(x) - b| < \varepsilon$ for $a - \delta < x < a$ (resp., for $a < x < a + \delta$).

Notation: $\lim\limits_{x\to a-0} f(x) = b$ or $f(a - 0) = b$ (resp., $\lim\limits_{x\to a+0} f(x) = b$ or $f(a + 0) = b$).

► Properties of limits.

Let a be a number or any of the symbols ∞, $+\infty$, $-\infty$.

1. If a function has a limit at some point, this limit is unique.
2. If c is a constant function of x, then $\lim\limits_{x\to a} c = c$.
3. If there exist $\lim\limits_{x\to a} f(x)$ and $\lim\limits_{x\to a} g(x)$, then

$$\begin{aligned}
&\lim_{x\to a}\big[f(x) \pm g(x)\big] = \lim_{x\to a} f(x) \pm \lim_{x\to a} g(x);\\
&\lim_{x\to a} cf(x) = c\lim_{x\to a} f(x) \qquad (c = \text{const});\\
&\lim_{x\to a} f(x)\cdot g(x) = \lim_{x\to a} f(x)\cdot \lim_{x\to a} g(x);\\
&\lim_{x\to a} \frac{f(x)}{g(x)} = \frac{\lim\limits_{x\to a} f(x)}{\lim\limits_{x\to a} g(x)} \qquad \Big(\text{if } g(x) \neq 0,\ \lim_{x\to a} g(x) \neq 0\Big).
\end{aligned}$$

4. Let $f(x) \le g(x)$ in a neighborhood of a point a ($x \neq a$). Then $\lim\limits_{x\to a} f(x) \le \lim\limits_{x\to a} g(x)$, provided that these limits exist.

5. If $f(x) \le g(x) \le h(x)$ in a neighborhood of a point a and $\lim\limits_{x\to a} f(x) = \lim\limits_{x\to a} h(x) = b$, then $\lim\limits_{x\to a} g(x) = b$.

These properties hold also for one-sided limits.

► Limits of some functions.

$$\textit{First noteworthy limit}: \qquad \lim_{x\to 0} \frac{\sin x}{x} = 1.$$

$$\textit{Second noteworthy limit}: \qquad \lim_{x\to \infty} \Big(1 + \frac{1}{x}\Big)^x = e.$$

Some other frequently used limits:

$$\lim_{x\to 0}\frac{(1+x)^n-1}{x}=n,\quad \lim_{x\to\infty}\frac{a_nx^n+a_{n-1}x^{n-1}+\cdots+a_1x+a_0}{b_nx^n+b_{n-1}x^{n-1}+\cdots+b_1x+b_0}=\frac{a_n}{b_n},$$

$$\lim_{x\to 0}\frac{1-\cos x}{x^2}=\frac{1}{2},\quad \lim_{x\to 0}\frac{\tan x}{x}=1,\quad \lim_{x\to 0}\frac{\arcsin x}{x}=1,\quad \lim_{x\to 0}\frac{\arctan x}{x}=1,$$

$$\lim_{x\to 0}\frac{e^x-1}{x}=1,\quad \lim_{x\to 0}\frac{a^x-1}{x}=\ln a,\quad \lim_{x\to 0}\frac{\ln(1+x)}{x}=1,\quad \lim_{x\to 0}\frac{\log_a(1+x)}{x}=\log_a e,$$

$$\lim_{x\to 0}\frac{\sinh x}{x}=1,\quad \lim_{x\to 0}\frac{\tanh x}{x}=1,\quad \lim_{x\to 0}\frac{\operatorname{arcsinh} x}{x}=1,\quad \lim_{x\to 0}\frac{\operatorname{arctanh} x}{x}=1,$$

$$\lim_{x\to +0}x^a\ln x=0,\quad \lim_{x\to +\infty}x^{-a}\ln x=0,\quad \lim_{x\to +\infty}x^ae^{-x}=0,\quad \lim_{x\to +0}x^x=1,$$

where $a>0$ and $b_n\neq 0$.

► See Subsection M6.2.3, where L'Hospital rules for calculating limits with the help of derivatives are given.

► **Asymptotes of the graph of a function.** An *asymptote* of the graph of a function $y=f(x)$ is a straight line whose distance from a point (x,y) on the graph of $y=f(x)$ tends to zero if at least one of the coordinates (x,y) tends to infinity.

The line $x=a$ is a *vertical asymptote* of the graph of the function $y=f(x)$ if at least one of the one-sided limits of $f(x)$ as $x\to a\pm 0$ is equal to $+\infty$ or $-\infty$.

The line $y=kx+b$ is an *oblique asymptote* of the graph of $y=f(x)$ if at least one of the limit relations holds:

$$\lim_{x\to+\infty}[f(x)-kx-b]=0\quad\text{or}\quad\lim_{x\to-\infty}[f(x)-kx-b]=0.$$

If there exist finite limits

$$\lim_{x\to+\infty}\frac{f(x)}{x}=k,\qquad \lim_{x\to+\infty}[f(x)-kx]=b,\tag{M6.1.3.2}$$

then the line $y=kx+b$ is an oblique asymptote of the graph for $x\to+\infty$ (in a similar way, one defines an asymptote for $x\to-\infty$).

Example. Let us find the asymptotes of the graph of the function $y=\dfrac{x^2}{x-1}$.

1°. The graph has a vertical asymptote $x=1$, since $\lim\limits_{x\to 1}\dfrac{x^2}{x-1}=\infty$.

2°. Moreover, for $x\to\pm\infty$, there is an oblique asymptote $y=kx+b$ whose coefficients are determined by the formulas (M6.1.3.2):

$$k=\lim_{x\to\pm\infty}\frac{x}{x-1}=1,\qquad b=\lim_{x\to\pm\infty}\left(\frac{x^2}{x-1}-x\right)=\lim_{x\to\pm\infty}\frac{x}{x-1}=1.$$

Thus, the equation of the oblique asymptote has the form $y=x+1$. Fig. M6.1 shows the graph of the function under consideration and its asymptotes.

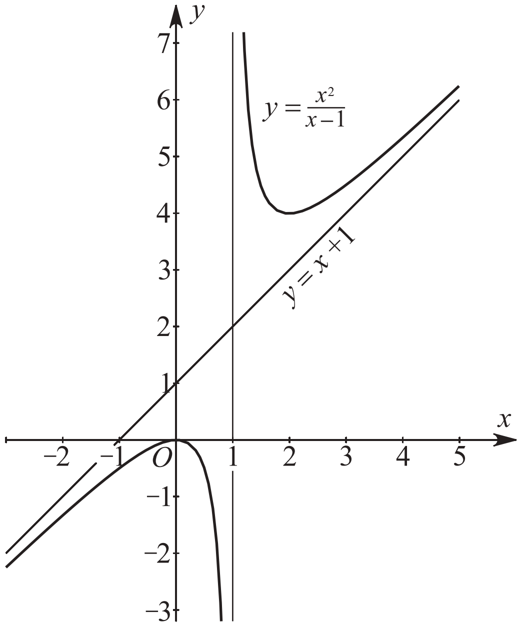

Figure M6.1. The graph of the function $y = \dfrac{x^2}{x-1}$ and its asymptotes.

M6.1.4. Infinitely Small and Infinitely Large Functions

► **Definitions.** A function $f(x)$ is called *infinitely small* for $x \to a$ if $\lim\limits_{x\to a} f(x) = 0$.

A function $f(x)$ is said to be *infinitely large* for $x \to a$ if for any $K > 0$ the inequality $|f(x)| > K$ holds for all $x \neq a$ in a small neighborhood of the point a. In this case, one writes $f(x) \to \infty$ as $x \to a$ or $\lim\limits_{x\to a} f(x) = \infty$. (In these definitions, a is a finite number or any of the symbols ∞, $+\infty$, $-\infty$.) If $f(x)$ is infinitely large for $x \to a$ and $f(x) > 0$ ($f(x) < 0$) in a neighborhood of a (for $x \neq a$), one writes $\lim\limits_{x\to a} f(x) = +\infty$ (resp., $\lim\limits_{x\to a} f(x) = -\infty$).

► **Properties of infinitely small and infinitely large functions.**

1. The sum and the product of finitely many infinitely small functions for $x \to a$ is an infinitely small function.

2. The product of an infinitely small function $f(x)$ for $x \to a$ and a function $g(x)$ which is bounded in a neighborhood U of the point a (i.e., $|g(x)| < M$ for all $x \in U$, where $M > 0$ is a constant) is an infinitely small function.

3. $\lim\limits_{x\to a} f(x) = b$ if and only if $f(x) = b + g(x)$, where $g(x)$ is infinitely small for $x \to a$.

4. A function $f(x)$ is infinitely large at some point if and only if the function $g(x) = 1/f(x)$ is infinitely small at the same point.

► **Comparison of infinitely small quantities. Symbols of the order: *O* and *o*.** Functions $f(x)$ and $g(x)$ that are infinitely small for $x \to a$ are called *equivalent* near a if $\lim\limits_{x\to a} \dfrac{f(x)}{g(x)} = 1$. In this case one writes $f(x) \sim g(x)$.

Examples of equivalent infinitely small functions:

$$(1+\varepsilon)^n - 1 \sim n\varepsilon, \qquad a^\varepsilon - 1 \sim \varepsilon \ln a, \qquad \log_a(1+\varepsilon) \sim \varepsilon \log_a e,$$
$$\sin\varepsilon \sim \varepsilon, \quad \tan\varepsilon \sim \varepsilon, \quad 1 - \cos\varepsilon \sim \tfrac{1}{2}\varepsilon^2, \quad \arcsin\varepsilon \sim \varepsilon, \quad \arctan\varepsilon \sim \varepsilon,$$

where $\varepsilon = \varepsilon(x)$ is infinitely small for $x \to a$.

Functions $f(x)$ and $g(x)$ are said to be of the *same order* for $x \to a$, and one writes $f(x) = O\bigl(g(x)\bigr)$ if $\lim\limits_{x\to a} \dfrac{f(x)}{g(x)} = K,\ 0 < |K| < \infty$.*

A function$f(x)$ is of a *higher order of smallness* compared with $g(x)$ for $x \to a$ if $\lim\limits_{x\to a} \dfrac{f(x)}{g(x)} = 0$, and in this case, one writes $f(x) = o\bigl(g(x)\bigr)$.

M6.1.5. Continuous Functions. Discontinuities of the First and the Second Kind

► **Continuous functions.** A function $f(x)$ is called *continuous* at a point $x = a$ if it is defined at that point and its neighborhood and $\lim\limits_{x\to a} f(x) = f(a)$.

For continuous functions, a small variation of their argument $\Delta x = x - a$ results in a small variation of the function $\Delta y = f(x) - f(a)$, i.e., $\Delta y \to 0$ as $\Delta x \to 0$. (This property is often used as a definition of continuity.)

A function $f(x)$ is called *right-continuous* at a point $x = a$ if it is defined at that point (and to its right) and $\lim\limits_{x\to a+0} f(x) = f(a)$. A function $f(x)$ is called *left-continuous* at a point $x = a$ if it is defined at that point (and to its left) and $\lim\limits_{x\to a-0} f(x) = f(a)$.

► **Properties of continuous functions.**

1. Suppose that functions $f(x)$ and $g(x)$ are continuous at some point a. Then the functions $f(x) \pm g(x)$, $cf(x)$, $f(x)g(x)$, $\dfrac{f(x)}{g(x)}$ $(g(a) \neq 0)$ are also continuous at a.

2. Suppose that a function $f(x)$ is continuous on the segment $[a, b]$ and takes values of different signs at its endpoints, i.e., $f(a)f(b) < 0$. Then there is a point c between a and b at which $f(x)$ vanishes:

$$f(c) = 0 \qquad (a < c < b).$$

3. If $f(x)$ is continuous at a point a and $f(a) > 0$ (resp., $f(a) < 0$), then there is $\delta > 0$ such that $f(x) > 0$ (resp., $f(x) < 0$) for all $x \in (a - \delta, a + \delta)$.

4. Any function $f(x)$ that is continuous at each point of a segment $[a, b]$ attains its largest and its smallest values, M and m, on that segment.

5. A function $f(x)$ that is continuous on a segment $[a, b]$ takes any value $c \in [m, M]$ on that segment, where m and M are, respectively, its smallest and its largest values on $[a, b]$.

6. If $f(x)$ is continuous and increasing (resp., decreasing) on a segment $[a, b]$, then on the segment $\bigl[f(a), f(b)\bigr]$ (resp., $\bigl[f(b), f(a)\bigr]$) the inverse function $x = g(y)$ exists, and is continuous and increasing (resp., decreasing).

7. If $u(x)$ is continuous at a point a and $f(u)$ is continuous at $b = u(a)$, then the composite function $f\bigl(u(x)\bigr)$ is continuous at a.

Remark. Any elementary function is continuous at each point of its domain.

► **Points of discontinuity of a function.** A point a is called a *point of discontinuity of the first kind* for a function $f(x)$ if there exist finite one-sided limits $f(a + 0)$ and $f(a - 0)$, but the relations $\lim\limits_{x\to a+0} f(x) = \lim\limits_{x\to a-0} f(x) = f(a)$ do not hold. The value $|f(a + 0) - f(a - 0)|$ is called the *jump* of the function at the point a. In particular, if $f(a + 0) = f(a - 0) \neq f(a)$, then a is called a *point of removable discontinuity*.

---

* There is another definition of the symbol O. Namely, $f(x) = O\bigl(g(x)\bigr)$ for $x \to a$ if the inequality $|f(x)| \le K|g(x)|$, $K =$ const, holds in some neighborhood of the point a (for $x \neq a$).

Examples of functions with discontinuities of the first kind.

1. The function $f(x) = \begin{cases} 0 & \text{for } x < 0 \\ 1 & \text{for } x \geq 0 \end{cases}$ has a jump equal to 1 at the discontinuity point $x = 0$.

2. The function $f(x) = \begin{cases} 0 & \text{for } x \neq 0 \\ 1 & \text{for } x = 0 \end{cases}$ has a removable discontinuity at the point $x = 0$.

A point a is called a *point of discontinuity of the second kind* if at least one of the one-sided limits $f(a+0)$ or $f(a-0)$ does not exist or is equal to infinity.

Examples of functions with discontinuities of the second kind.

1. The function $f(x) = \sin\dfrac{1}{x}$ has a second-kind discontinuity at the point $x = 0$ (since this function has no one-sided limits as $x \to \pm 0$).

2. The function $f(x) = 1/x$ has an infinite limit as $x \to 0$, so it has a second-kind discontinuity at the point $x = 0$.

M6.1.6. Convex and Concave Functions

► Definition of convex and concave functions.

1°. A function $f(x)$ defined and continuous on a segment $[a, b]$ is called *convex* (or *convex downward*) if for any x_1, x_2 in $[a, b]$, the *Jensen inequality* holds:

$$f\left(\frac{x_1 + x_2}{2}\right) \leq \frac{f(x_1) + f(x_2)}{2}. \qquad \text{(M6.1.6.1)}$$

The geometrical meaning of convexity is that all points of the graph curve between two graph points lie below or on the rectilinear segment joining the two graph points (see Fig. M6.2 *a*).

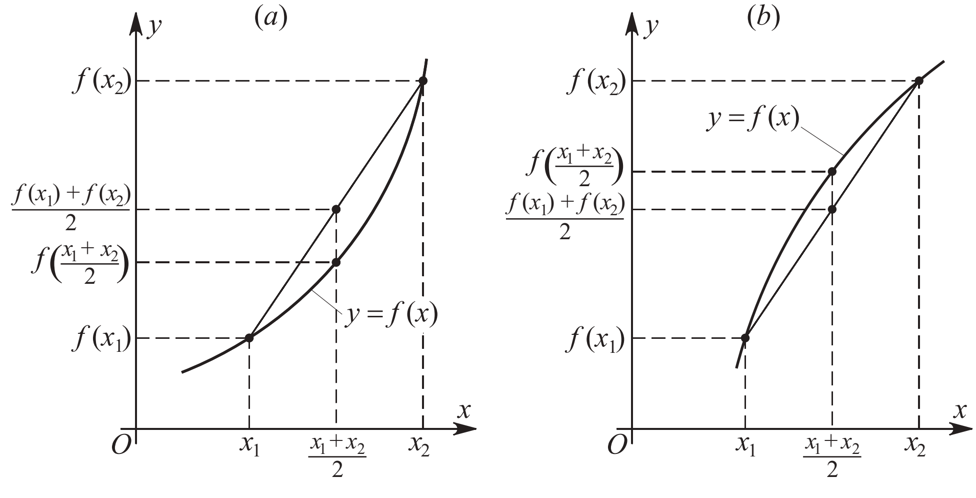

Figure M6.2. Graphs of convex (*a*) and concave (*b*) functions.

If for $x_1 \neq x_2$, condition (M6.1.6.1) holds with < instead of ≤, then the function $f(x)$ is called *strictly convex*.

2°. A function $f(x)$ defined and continuous on a segment $[a, b]$ is called *concave* (or *convex upward*) if for any x_1, x_2 in $[a, b]$ the following inequality holds:

$$f\left(\frac{x_1 + x_2}{2}\right) \geq \frac{f(x_1) + f(x_2)}{2}. \qquad \text{(M6.1.6.2)}$$

The geometrical meaning of concavity is that all points of the graph curve between two graph points lie above or on the rectilinear segment joining the two graph points (see Fig. M6.2 *b*).

If for $x_1 \neq x_2$, condition (M6.1.6.2) holds with > instead of ≥, then the function $f(x)$ is called *strictly concave*.

► **Some properties of convex and concave functions.**

1. The product of a convex (concave) function and a positive constant is a convex (concave) function.

2. The sum of two or more convex (concave) functions is a convex (concave) function.

3. A non-constant convex (resp., concave) function $f(x)$ on a segment $[a, b]$ cannot attain its largest (resp., smallest) value inside the segment.

4. A function $f(x)$ that is continuous on a segment $[a, b]$ and twice differentiable on the interval (a, b) is convex downward (resp., convex upward) if and only if $f''(x) \geq 0$ (resp., $f''(x) \leq 0$) on that interval.

M6.1.7. Convergence of Functions

► **Pointwise, uniform, and nonuniform convergence of functions.** Let $\{f_n(x)\}$ be a sequence of functions defined on a set $X \subset \mathbb{R}$. The sequence $\{f_n(x)\}$ is said to be *pointwise convergent* to $f(x)$ as $n \to \infty$ if for any fixed $x \in X$, the numerical sequence $\{f_n(x)\}$ converges to $f(x)$. The sequence $\{f_n(x)\}$ is said to be *uniformly convergent* to a function $f(x)$ on X as $n \to \infty$ if for any $\varepsilon > 0$ there is an integer $N = N(\varepsilon)$ such that for all $n > N$ and all $x \in X$, the following inequality holds:

$$|f_n(x) - f(x)| < \varepsilon. \qquad \text{(M6.1.7.1)}$$

Note that in this definition, N is independent of x. For a sequence $\{f_n(x)\}$ pointwise convergent to $f(x)$ as $n \to \infty$, by definition, for any $\varepsilon > 0$ and any $x \in X$, there is $N = N(\varepsilon, x)$ such that (M6.1.7.1) holds for all $n > N(\varepsilon, x)$.

If one cannot find such an N independent of x and depending only on ε (i.e., one cannot ensure (M6.1.7.1) uniformly; to be more precise, there is an $\varepsilon > 0$ such that for any $N > 0$ there is a $k_N > N$ and $x_N \in X$ such that $|f_{k_N}(x_N) - f(x_N)| \geq \varepsilon$), then one says that the sequence $\{f_n(x)\}$ *converges nonuniformly* to $f(x)$ on the set X.

► **Basic theorems.** Let X be an interval on the real axis.

THEOREM. *Let $f_n(x)$ be a sequence of continuous functions uniformly convergent to $f(x)$ on X. Then $f(x)$ is continuous on X.*

COROLLARY. *If the limit function $f(x)$ of a pointwise convergent sequence of continuous functions $\{f_n(x)\}$ is discontinuous, then the convergence of the sequence $\{f_n(x)\}$ is nonuniform.*

Example. The sequence $\{f_n(x)\} = \{x^n\}$ converges to $f(x) \equiv 0$ as $n \to \infty$ uniformly on each segment $[0, a]$, $0 < a < 1$. However, on the segment $[0, 1]$ this sequence converges nonuniformly to the discontinuous function $f(x) = \begin{cases} 0 & \text{for } 0 \leq x < 1, \\ 1 & \text{for } x = 1. \end{cases}$

CAUCHY CRITERION. *A sequence of functions $\{f_n(x)\}$ defined on a set $X \in \mathbb{R}$ uniformly converges to $f(x)$ as $n \to \infty$ if and only if for any $\varepsilon > 0$ there is an integer $N = N(\varepsilon) > 0$ such that for all $n > N$ and $m > N$, the inequality $|f_n(x) - f_m(x)| < \varepsilon$ holds for all $x \in X$.*

► **Geometrical meaning of uniform convergence.** Let $f_n(x)$ be continuous functions on the segment $[a, b]$ and suppose that $\{f_n(x)\}$ uniformly converges to a continuous function $f(x)$ as $n \to \infty$. Then all curves $y = f_n(x)$, for sufficiently large $n > N$, belong to the strip between the two curves $y = f(x) - \varepsilon$ and $y = f(x) + \varepsilon$ (see Fig. M6.3).

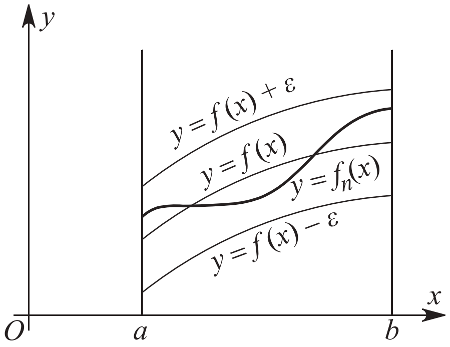

Figure M6.3. Geometrical meaning of uniform convergence of a sequence of functions $\{f_n(x)\}$ to a continuous function $f(x)$.

M6.2. Differential Calculus for Functions of a Single Variable

M6.2.1. Derivative and Differential: Their Geometrical and Physical Meaning

► **Definition of derivative and differential.** The *derivative* of a function $y = f(x)$ at a point x is the limit of the ratio

$$y' = \lim_{\Delta x \to 0} \frac{\Delta y}{\Delta x} = \lim_{\Delta x \to 0} \frac{f(x + \Delta x) - f(x)}{\Delta x},$$

where $\Delta y = f(x+\Delta x) - f(x)$ is the increment of the function corresponding to the increment of the argument Δx. The derivative y' is also denoted by y'_x, $\dot{y}$, $\dfrac{dy}{dx}$, $f'(x)$, $\dfrac{df(x)}{dx}$.

Example 1. Let us calculate the derivative of the function $f(x) = x^2$.
By definition, we have

$$f'(x) = \lim_{\Delta x \to 0} \frac{(x + \Delta x)^2 - x^2}{\Delta x} = \lim_{\Delta x \to 0} (2x + \Delta x) = 2x.$$

The increment Δx is also called the differential of the independent variable x and is denoted by dx.

A function $f(x)$ that has a derivative at a point x is called *differentiable* at that point. The differentiability of $f(x)$ at a point x is equivalent to the condition that the increment of the function, $\Delta y = f(x + dx) - f(x)$, at that point can be represented in the form $\Delta y = f'(x)\,dx + o(dx)$ (the second term is an infinitely small quantity compared with dx as $dx \to 0$; see Subsection M6.1.4).

A function differentiable at some point x is continuous at that point. The converse is not true, in general; continuity does not always imply differentiability.

A function $f(x)$ is called *differentiable* on a set D (interval, segment, etc.) if for any $x \in D$ there exists the derivative $f'(x)$. A function $f(x)$ is called *continuously differentiable* on D if it has the derivative $f'(x)$ at each point $x \in D$ and $f'(x)$ is a continuous function on D.

The *differential* dy of a function $y = f(x)$ is the principal linear part of its increment Δy at the point x, so that $dy = f'(x)dx$, $\Delta y = dy + o(dx)$.

The approximate relation $\Delta y \approx dy$ or $f(x + \Delta x) \approx f(x) + f'(x)\Delta x$ (for small Δx) is often used in numerical analysis.

► Physical and geometrical meaning of the derivative. Tangent line.

1°. Let $y = f(x)$ be the function describing the path y traversed by a body by the time x. Then the derivative $f'(x)$ is the velocity of the body at the instant x.

2°. The *tangent line* or simply the *tangent* to the graph of the function $y = f(x)$ at a point $M(x_0, y_0)$, where $y_0 = f(x_0)$, is defined as the straight line determined by the limit position of the secant MN as the point N tends to M along the graph. If α is the angle between the x-axis and the tangent line, then $f'(x_0) = \tan\alpha$ is the slope ratio of the tangential line (Fig. M6.4).

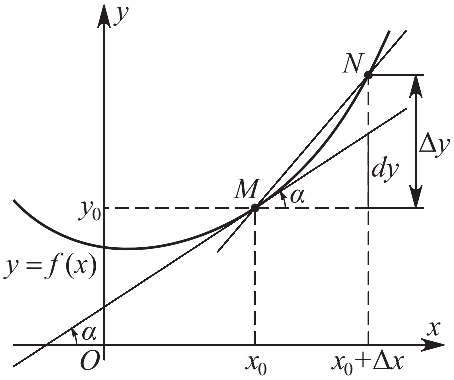

Figure M6.4. The tangent to the graph of a function $y = f(x)$ at a point (x_0, y_0).

Equation of the tangent line to the graph of a function $y = f(x)$ at a point (x_0, y_0):

$$y - y_0 = f'(x_0)(x - x_0).$$

Equation of the normal to the graph of a function $y = f(x)$ at a point (x_0, y_0):

$$y - y_0 = -\frac{1}{f'(x_0)}(x - x_0).$$

M6.2.2. Table of Derivatives and Differentiation Rules

The derivative of any elementary function can be calculated with the help of derivatives of basic elementary functions and differentiation rules.

► Table of derivatives of basic elementary functions (a = const).

$$(a)' = 0, \qquad (x^a)' = ax^{a-1},$$
$$(e^x)' = e^x, \qquad (a^x)' = a^x \ln a,$$
$$(\ln x)' = \frac{1}{x}, \qquad (\log_a x)' = \frac{1}{x\ln a},$$
$$(\sin x)' = \cos x, \qquad (\cos x)' = -\sin x,$$
$$(\tan x)' = \frac{1}{\cos^2 x}, \qquad (\cot x)' = -\frac{1}{\sin^2 x},$$
$$(\arcsin x)' = \frac{1}{\sqrt{1-x^2}}, \qquad (\arccos x)' = -\frac{1}{\sqrt{1-x^2}},$$
$$(\arctan x)' = \frac{1}{1+x^2}, \qquad (\text{arccot}\, x)' = -\frac{1}{1+x^2},$$
$$(\sinh x)' = \cosh x, \qquad (\cosh x)' = \sinh x,$$

$$(\tanh x)' = \frac{1}{\cosh^2 x}, \qquad (\coth x)' = -\frac{1}{\sinh^2 x},$$
$$(\operatorname{arcsinh} x)' = \frac{1}{\sqrt{1+x^2}}, \qquad (\operatorname{arccosh} x)' = \frac{1}{\sqrt{x^2-1}},$$
$$(\operatorname{arctanh} x)' = \frac{1}{1-x^2} \quad (x^2 < 1), \qquad (\operatorname{arccoth} x)' = \frac{1}{1-x^2} \quad (x^2 > 1).$$

► **Differentiation rules.**

1. *Derivative of the sum (difference) of functions*:

$$[u(x) \pm v(x)]' = u'(x) \pm v'(x).$$

2. *Derivative of the product of a function and a constant*:

$$[au(x)]' = au'(x) \qquad (a = \text{const}).$$

3. *Derivative of the product of functions*:

$$[u(x)v(x)]' = u'(x)v(x) + u(x)v'(x).$$

4. *Derivative of the quotient of functions*:

$$\left[\frac{u(x)}{v(x)}\right]' = \frac{u'(x)v(x) - u(x)v'(x)}{v^2(x)}.$$

5. *Derivative of a composite function*:

$$\big[f(u(x))\big]' = f'_u(u)u'(x).$$

6. *Derivative of a parametrically defined function* $x = x(t)$, $y = y(t)$:

$$y'_x = \frac{y'_t}{x'_t}.$$

7. *Derivative of an implicit function defined by the equation* $F(x, y) = 0$:

$$y'_x = -\frac{F_x}{F_y} \qquad (F_x \text{ and } F_y \text{ are partial derivatives}).$$

8. *Derivative of the inverse function* $x = x(y)$ (for details see footnote*):

$$x'_y = \frac{1}{y'_x}.$$

9. *Derivative of a composite exponential function*:

$$[u(x)^{v(x)}]' = u'vu^{v-1} + v'u^v \ln u = u^v\Big(u'\frac{v}{u} + v' \ln u\Big).$$

---

* Let $y = f(x)$ be a differentiable monotone function on the interval (a, b) and $f'(x_0) \neq 0$, where $x_0 \in (a, b)$. Then the inverse function $x = g(y)$ is differentiable at the point $y_0 = f(x_0)$ and $g'(y_0) = \dfrac{1}{f'(x_0)}$.

10. *Derivative of a composite function of two arguments*:

$$\bigl[f\bigl(u(x),v(x)\bigr)\bigr]' = f_u(u,v)u' + f_v(u,v)v' \qquad (f_u \text{ and } f_v \text{ are partial derivatives}).$$

11. *Logarithmic derivative*:

$$[\ln u(x)]' = \frac{u'(x)}{u(x)}.$$

Example 1. Let us calculate the derivative of the function $\dfrac{x^2}{2x+1}$.
Using the rule of differentiating the ratio of two functions, we obtain

$$\left(\frac{x^2}{2x+1}\right)' = \frac{(x^2)'(2x+1) - x^2(2x+1)'}{(2x+1)^2} = \frac{2x(2x+1)-2x^2}{(2x+1)^2} = \frac{2x^2+2x}{(2x+1)^2}.$$

Example 2. Let us calculate the derivative of the function $\ln\cos x$.
Using the chain rule or the logarithmic derivative formula, we get

$$(\ln\cos x)' = \frac{1}{\cos x}(\cos x)' = -\tan x.$$

Example 3. Let us calculate the derivative of the function x^x. Using the rule of differentiating the composite exponential function with $u(x) = v(x) = x$, we have

$$(x^x)' = x^x \ln x + x x^{x-1} = x^x(\ln x + 1).$$

M6.2.3. Theorems about Differentiable Functions. L'Hospital Rule

► Main theorems about differentiable functions.

ROLLE THEOREM. *If the function $y = f(x)$ is continuous on the segment $[a,b]$, differentiable on the interval (a,b), and $f(a) = f(b)$, then there is a point $c \in (a,b)$ such that $f'(c) = 0$.*

LAGRANGE THEOREM. *If the function $y = f(x)$ is continuous on the segment $[a,b]$ and differentiable on the interval (a,b), then there is a point $c \in (a,b)$ such that*

$$f(b) - f(a) = f'(c)(b-a).$$

This relation is called the *formula of finite increments*.

CAUCHY THEOREM. *Let $f(x)$ and $g(x)$ be two functions that are continuous on the segment $[a,b]$, differentiable on the interval (a,b), and $g'(x) \neq 0$ for all $x \in (a,b)$. Then there is a point $c \in (a,b)$ such that*

$$\frac{f(b)-f(a)}{g(b)-g(a)} = \frac{f'(c)}{g'(c)}.$$

► L'Hospital's rules on indeterminate expressions of the form $0/0$ and ∞/∞.

THEOREM 1. *Let $f(x)$ and $g(x)$ be two functions defined in a neighborhood of a point a, vanishing at this point, $f(a) = g(a) = 0$, and having the derivatives $f'(a)$ and $g'(a)$, with $g'(a) \neq 0$. Then*

$$\lim_{x\to a} \frac{f(x)}{g(x)} = \frac{f'(a)}{g'(a)}.$$

Example 1. Let us calculate the limit $\displaystyle\lim_{x\to 0} \frac{\sin x}{1-e^{-2x}}$.
Here, both the numerator and the denominator vanish for $x = 0$. Let us calculate the derivatives

$$f'(x) = (\sin x)' = \cos x \qquad \Longrightarrow \qquad f'(0) = 1,$$

$$g'(x) = (1-e^{-2x})' = 2e^{-2x} \qquad \Longrightarrow \qquad g'(0) = 2 \neq 0.$$

By the L'Hospital rule, we find that

$$\lim_{x\to 0} \frac{\sin x}{1-e^{-2x}} = \frac{f'(0)}{g'(0)} = \frac{1}{2}.$$

THEOREM 2. *Let $f(x)$ and $g(x)$ be two functions defined in a neighborhood of a point a, vanishing at a, together with their derivatives up to the order $n-1$ inclusively. Suppose also that the derivatives $f^{(n)}(a)$ and $g^{(n)}(a)$ exist and are finite, $g^{(n)}(a) \neq 0$. Then*

$$\lim_{x\to a} \frac{f(x)}{g(x)} = \frac{f^{(n)}(a)}{g^{(n)}(a)}.$$

THEOREM 3. *Let $f(x)$ and $g(x)$ be differentiable functions and $g'(x) \neq 0$ in a neighborhood of a point a $(x \neq a)$. If $f(x)$ and $g(x)$ are infinitely small or infinitely large functions for $x \to a$, i.e., the ratio $\dfrac{f(x)}{g(x)}$ at the point a is an indeterminate expression of the form $\dfrac{0}{0}$ or $\dfrac{\infty}{\infty}$, then*

$$\lim_{x\to a} \frac{f(x)}{g(x)} = \lim_{x\to a} \frac{f'(x)}{g'(x)}$$

(provided that there exists a finite or infinite limit of the ratio of the derivatives).

Remark. The L'Hospital rule 3 is applicable also in the case of a being one of the symbols ∞, $+\infty$, $-\infty$.

► **Methods for interpreting other indeterminate expressions.**

1°. Expressions of the form $0\cdot\infty$ and $\infty-\infty$ can be reduced to indeterminate expressions $\dfrac{0}{0}$ or $\dfrac{\infty}{\infty}$ by means of algebraic transformations, for instance:

$$u(x)\,v(x) = \frac{u(x)}{1/v(x)} \qquad \text{transformation rule} \quad 0\cdot\infty \Longrightarrow \frac{0}{0},$$

$$u(x)-v(x) = \left(\frac{1}{v(x)} - \frac{1}{u(x)}\right) : \frac{1}{u(x)v(x)} \qquad \text{transformation rule} \quad \infty-\infty \Longrightarrow \frac{0}{0}.$$

2°. Indeterminate expressions of the form 1^∞, ∞^0, 0^0 can be reduced to expressions of the form $\dfrac{0}{0}$ or $\dfrac{\infty}{\infty}$ by taking logarithm and using the formulas $\ln u^v = v\ln u = \dfrac{\ln u}{1/v}$.

Example 2. Let us calculate the limit $\lim\limits_{x\to 0}(\cos x)^{1/x^2}$.

We have the indeterminate expression 1^∞. We find that

$$\ln \lim_{x\to 0}(\cos x)^{1/x^2} = \lim_{x\to 0}\ln(\cos x)^{1/x^2} = \lim_{x\to 0}\frac{\ln\cos x}{x^2} = \lim_{x\to 0}\frac{(\ln\cos x)'}{(x^2)'} = \lim_{x\to 0}\frac{(-\tan x)}{2x} = -\frac{1}{2}.$$

Therefore, $\lim\limits_{x\to 0}(\cos x)^{1/x^2} = e^{-1/2} = \dfrac{1}{\sqrt{e}}$.

M6.2.4. Higher-Order Derivatives and Differentials. Taylor's Formula

► **Derivatives and differentials of higher orders.** The *second-order derivative* or the second derivative of a function $y = f(x)$ is the derivative of the derivative $f'(x)$. The second derivative is denoted by y'' and also by y''_{xx}, $\dfrac{d^2y}{dx^2}$, $f''(x)$.

The derivative of the second derivative of a function $y = f(x)$ is called the third-order derivative, $y''' = (y'')'$. The nth-order derivative of the function $y = f(x)$ is defined as the derivative of its $(n-1)$th derivative:

$$y^{(n)} = (y^{(n-1)})'.$$

The nth-order derivative is also denoted by $y_x^{(n)}$, $\dfrac{d^n y}{dx^n}$, $f^{(n)}(x)$.

The *second-order differential* is the differential of the first-order differential, $d^2y = d(dy)$. If x is the independent variable, then $d^2y = y'' \cdot (dx)^2$. In a similar way, one defines differentials of higher orders.

► **Table of higher-order derivatives of some elementary functions.**

$$(x^a)^{(n)} = a(a-1)\dots(a-n+1)x^{a-n}, \qquad (a^x)^{(n)} = (\ln a)^n a^x,$$

$$(\ln x)^{(n)} = (-1)^{n-1}(n-1)!\,\frac{1}{x^n}, \qquad (\log_a x)^{(n)} = (-1)^{n-1}\frac{(n-1)!}{\ln a}\,\frac{1}{x^n},$$

$$(\sin x)^{(n)} = \sin\left(x + \frac{\pi n}{2}\right), \qquad (\cos x)^{(n)} = \cos\left(x + \frac{\pi n}{2}\right),$$

$$(\sinh x)^{(n)} = \begin{cases} \cosh x & \text{if } n \text{ is odd,} \\ \sinh x & \text{if } n \text{ is even,} \end{cases} \qquad (\cosh x)^{(n)} = \begin{cases} \cosh x & \text{if } n \text{ is even,} \\ \sinh x & \text{if } n \text{ is odd.} \end{cases}$$

► **Rules for calculating higher-order derivatives.**

1. *Derivative of a sum (difference) of functions*:

$$[u(x) \pm v(x)]^{(n)} = u^{(n)}(x) \pm v^{(n)}(x).$$

2. *Derivatives of a function multiplied by a constant*:

$$[au(x)]^{(n)} = au^{(n)}(x) \qquad (a = \text{const}).$$

3. *Derivatives of a product*:

$$[u(x)v(x)]'' = u''(x)v(x) + 2u'(x)v'(x) + u(x)v''(x),$$
$$[u(x)v(x)]''' = u'''(x)v(x) + 3u''(x)v'(x) + 3u'(x)v''(x) + u(x)v'''(x),$$
$$[u(x)v(x)]^{(n)} = \sum_{k=0}^{n} C_n^k u^{(k)}(x)v^{(n-k)}(x) \qquad \text{(Leibniz formula),}$$

where C_n^k are binomial coefficients, $u^{(0)}(x) = u(x)$, $v^{(0)}(x) = v(x)$.

4. *Derivatives of a composite function*:

$$\big[f(u(x))\big]'' = f''_{uu}(u'_x)^2 + f'_u u''_{xx},$$
$$\big[f(u(x))\big]''' = f'''_{uuu}(u'_x)^3 + 3f''_{uu}u'_x u''_{xx} + f'_u u'''_{xxx}.$$

5. *Derivatives of a parametrically defined function* $x = x(t)$, $y = y(t)$:

$$y'' = \frac{x'_t y''_{tt} - y'_t x''_{tt}}{(x'_t)^3}, \quad y''' = \frac{(x'_t)^2 y'''_{ttt} - 3x'_t x''_{tt} y''_{tt} + 3y'_t (x''_{tt})^2 - x'_t y'_t x'''_{ttt}}{(x'_t)^5}, \quad y^{(n)} = \frac{(y^{(n-1)})'_t}{x'_t}.$$

6. *Derivatives of an implicit function defined by the equation* $F(x, y) = 0$:

$$y'' = \frac{1}{F_y^3}\big(-F_y^2 F_{xx} + 2F_x F_y F_{xy} - F_x^2 F_{yy}\big),$$
$$y''' = \frac{1}{F_y^5}\big(-F_y^4 F_{xxx} + 3F_x F_y^3 F_{xxy} - 3F_x^2 F_y^3 F_{xyy} + F_x^3 F_y F_{yyy} + 3F_y^3 F_{xx} F_{xy}$$
$$- 3F_x F_y^2 F_{xx} F_{yy} - 6F_x F_y^2 F_{xy}^2 - 3F_x^3 F_{yy}^2 + 9F_x^2 F_y F_{xy} F_{yy}\big),$$

where the subscripts denote the corresponding partial derivatives.

7. *Derivatives of the inverse function* $x = x(y)$:

$$x''_{yy} = -\frac{y''_{xx}}{(y'_x)^3}, \qquad x'''_{yyy} = -\frac{y'''_{xxx}}{(y'_x)^4} + 3\frac{(y''_{xx})^2}{(y'_x)^5}, \qquad x^{(n)}_y = \frac{1}{y'_x}[x^{(n-1)}_y]'_x.$$

► **Taylor's formula.** Suppose that in a neighborhood of a point $x = a$, the function $y = f(x)$ has derivatives up to the order $(n + 1)$ inclusively. Then for all x in that neighborhood, the following representation holds:

$$f(x) = f(a) + \frac{f'(a)}{1!}(x-a) + \frac{f''(a)}{2!}(x-a)^2 + \cdots + \frac{f^{(n)}(a)}{n!}(x-a)^n + R_n(x), \quad \text{(M6.2.4.1)}$$

where $R_n(x)$ is the *remainder term* in Taylor's formula.

The remainder term can be represented in different forms:

$$R_n(x) = o[(x-a)^n] \qquad \text{(Peano)},$$

$$R_n(x) = \frac{f^{(n+1)}\big(a + k(x-a)\big)}{(n+1)!}(x-a)^{n+1} \qquad \text{(Lagrange)},$$

$$R_n(x) = \frac{f^{(n+1)}\big(a + k(x-a)\big)}{n!}(1-k)^n(x-a)^{n+1} \qquad \text{(Cauchy)},$$

$$R_n(x) = \frac{f^{(n+1)}\big(a + k(x-a)\big)}{n!\,p}(1-k)^{n+1-p}(x-a)^{n+1} \qquad \text{(Schlömilch and Roche)},$$

$$R_n(x) = \frac{1}{n!}\int_a^x f^{(n+1)}(t)(x-t)^n\,dt \qquad \text{(integral form)},$$

where $0 < k < 1$ and $p > 0$; k depends on x, n, and the structure of the remainder term. The remainders in the form of Lagrange and Cauchy can be obtained as special cases of the Schlömilch formula with $p = n + 1$ and $p = 1$, respectively.

For $a = 0$, the Taylor's formula (M6.2.4.1) turns into

$$f(x) = f(0) + \frac{f'(0)}{1!}x + \frac{f''(0)}{2!}x^2 + \cdots + \frac{f^{(n)}(0)}{n!}x^n + R_n(x)$$

and is called the *Maclaurin formula*.

The Maclaurin formula for some functions:

$$e^x = 1 + \frac{x}{1!} + \frac{x^2}{2!} + \frac{x^3}{3!} + \cdots + \frac{x^n}{n!} + R_n(x),$$

$$\sin x = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \cdots + (-1)^n\frac{x^{2n+1}}{(2n+1)!} + R_{2n+1}(x),$$

$$\cos x = 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \cdots + (-1)^n\frac{x^{2n}}{(2n)!} + R_{2n}(x).$$

M6.2.5. Extremal Points. Points of Inflection

► **Maximum and minimum. Points of extremum.** Let $f(x)$ be a differentiable function on the interval (a, b) and $f'(x) > 0$ (resp., $f'(x) < 0$) on (a, b). Then $f(x)$ is an *increasing* (resp., *decreasing*) function on that interval*.

Suppose that there is a neighborhood of a point x_0 such that for all $x \neq x_0$ in that neighborhood we have $f(x) > f(x_0)$ (resp., $f(x) < f(x_0)$). Then x_0 is called a point of *local minimum* (resp., *local maximum*) of the function $f(x)$.

Points of local minimum or maximum are called points of *extremum*.

---

* At some isolated points of the interval, the derivative may vanish.

► **Necessary and sufficient conditions for the existence of extremum.** Suppose that $f(x)$ is continuous in some neighborhood $(x_0-\delta,\ x_0+\delta)$ of a point x_0 and differentiable at all points of the neighborhood except, possibly, x_0.

NECESSARY CONDITION OF EXTREMUM. *A function $f(x)$ can have an extremum only at points in which its derivative either vanishes or does not exist (or is infinite).*

FIRST SUFFICIENT CONDITION OF EXTREMUM. *If $f'(x)>0$ for $x\in(x_0-\delta,\ x_0)$ and $f'(x)<0$ for $x\in(x_0,\ x_0+\delta)$, then x_0 is a point of local maximum of this function. If $f'(x)<0$ for $x\in(x_0-\delta,\ x_0)$ and $f'(x)>0$ for $x\in(x_0,\ x_0+\delta)$, then x_0 is a point of local minimum of this function.*

If $f'(x)$ is of the same sign for all $x\neq x_0$, $x\in(x_0-\delta,\ x_0+\delta)$, then x_0 cannot be a point of extremum.

SECOND SUFFICIENT CONDITION OF EXTREMUM. *Let $f(x)$ be a twice differentiable function in a neighborhood of x_0. Then the following statements hold:*

$$\begin{aligned}&\text{(i)}\quad f'(x_0)=0\ \text{ and }\ f''(x_0)<0 \quad\Longrightarrow\quad f(x)\ \text{has a local maximum at the point}\ x_0;\\&\text{(ii)}\quad f'(x_0)=0\ \text{ and }\ f''(x_0)>0 \quad\Longrightarrow\quad f(x)\ \text{has a local minimum at the point}\ x_0.\end{aligned}$$

THIRD SUFFICIENT CONDITION OF EXTREMUM. *Let $f(x)$ be a function that is n times differentiable in a neighborhood of a point x_0 and $f'(x_0)=f''(x_0)=\cdots=f^{(n-1)}(x_0)=0$, but $f^{(n)}(x_0)\neq 0$. Then the following statements hold:*

$$\begin{aligned}&\textit{(i)}\quad n\ \text{is even and}\ f^{(n)}(x_0)<0 \quad\Longrightarrow\quad f(x)\ \text{has a local maximum at the point}\ x_0;\\&\textit{(ii)}\quad n\ \text{is even and}\ f^{(n)}(x_0)>0 \quad\Longrightarrow\quad f(x)\ \text{has a local minimum at the point}\ x_0.\end{aligned}$$

If n is odd, then x_0 cannot be a point of extremum.

► **Largest and the smallest values of a function.** Let $y=f(x)$ be continuous on the segment $[a,b]$ and differentiable at all points of this segment except, possibly, finitely many points. Then the largest and the smallest values of $f(x)$ on $[a,b]$ belong to the set consisting of $f(a)$, $f(b)$, and the values $f(x_i)$, where $x_i\in(a,b)$ are the points at which $f'(x)$ is either equal to zero or does not exist (is infinite).

► **Direction of the convexity of the graph of a function.** The graph of a differentiable function $y=f(x)$ is said to be *convex upward* (resp., *convex downward*) on the interval (a,b) if for each point of this interval, the graph lies below (resp., above) the tangent line at that point.

If the function $y=f(x)$ is twice differentiable on the interval (a,b) and $f''(x)<0$ (resp., $f''(x)>0$), then its graph is convex upward (resp., downward) on that interval. (At some isolated points of the interval, the second derivative may vanish.)

Thus, in order to find the intervals on which the graph of a twice differentiable function $f(x)$ is convex upward (resp., downward), one should solve the inequality $f''(x)<0$ (resp., $f''(x)>0$).

► **Inflection points.** An *inflection point* on the graph of a function $y=f(x)$ is defined as a point $(x_0,\ f(x_0))$ at which the graph passes from one side of its tangent line to another. At an inflection point, the graph changes the direction of its convexity.

Suppose that the function $y=f(x)$ has a continuous second derivative $f''(x)$ in some neighborhood of a point x_0. If $f''(x_0)=0$ and $f''(x)$ changes sign as x passes through the point x_0, then $(x_0,\ f(x_0))$ is an inflection point.

M6.2.6. Qualitative Analysis of Functions and Construction of Graphs

► **General scheme of analysis of a function and construction of its graph.**

1. Determine the domain in which the function is defined.
2. Determine whether the function is odd or even and whether it is periodic.
3. Find the points at which the graph crosses the coordinate axes.
4. Find the asymptotes of the graph.
5. Find extremal points and intervals of monotonicity.
6. Determine the directions of convexity of the graph and its inflection points.
7. Draw the graph, using the properties 1 to 6.

Example. Let us examine the function $y = \dfrac{\ln x}{x}$ and construct its graph.

We use the above general scheme.

1. This function is defined for all x such that $0 < x < +\infty$.

2. This function is neither odd nor even, since it is defined only for $x > 0$ and the relations $f(-x) = f(x)$ or $f(-x) = -f(x)$ cannot hold. Obviously, this function is nonperiodic.

3. The graph of this function does not cross the y-axis, since for $x = 0$ the function is undefined. Further, $y = 0$ only if $x = 1$, i.e., the graph crosses the x-axis only at the point $(1, 0)$.

4. The straight line $x = 0$ is a vertical asymptote, since $\lim\limits_{x\to+0} \dfrac{\ln x}{x} = -\infty$. We find the oblique asymptotes:

$$k = \lim_{x\to+\infty} \frac{y}{x} = 0, \qquad b = \lim_{x\to+\infty} (y - kx) = 0.$$

Therefore, the line $y = 0$ is a horizontal asymptote of the graph.

5. The derivative $y' = \dfrac{1 - \ln x}{x^2}$ vanishes for $\ln x = 1$. Therefore, the function may have an extremum at $x = e$. For $x \in (0, e)$, we have $y' > 0$, i.e., the function is increasing on this interval. For $x \in (e, +\infty)$, we have $y' < 0$, and therefore the function is decreasing on this interval. At $x = e$ the function attains its maximal value $y_{\max} = \dfrac{1}{e}$.

One should also examine the points at which the derivative does not exist. There is only one such point, $x = 0$, and it corresponds to the vertical asymptote (see Item 4).

6. The second derivative $y'' = \dfrac{2\ln x - 3}{x^3}$ vanishes for $x = e^{3/2}$. On the interval $(0, e^{3/2})$, we have $y'' < 0$, and therefore the graph is convex upward on this interval. For $x \in (e^{3/2}, +\infty)$, we have $y'' > 0$, and therefore the graph is convex downward on this interval. The value $x = e^{3/2}$ corresponds to an inflection point of the graph, with the ordinate $y = \frac{3}{2}e^{-3/2}$.

7. Using the above results, we construct the graph (Fig. M6.5).

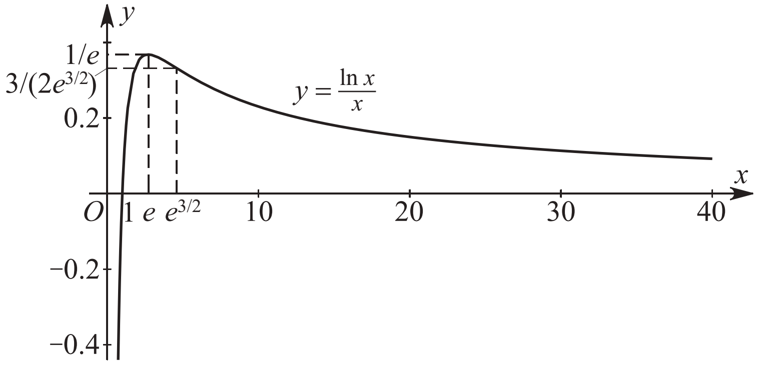

Figure M6.5. Graph of the function $y = \frac{\ln x}{x}$.

► **Transformations of graphs of functions.** Let us describe some methods which in many cases allow us to construct the graph of a function if we have the graph of a simpler function.

1. The graph of the function $y = f(x) + a$ is obtained from that of $y = f(x)$ by shifting the latter along the axis Oy by the distance $|a|$. For $a > 0$ the shift is upward, and for $a < 0$ downward (see Fig. M6.6 a).

Figure M6.6. Transformations of graphs of functions.

2. The graph of the function $y = f(x + a)$ is obtained from that of $y = f(x)$ by shifting the latter along the Ox by the distance $|a|$. For $a > 0$ the shift is to the left, and for $a < 0$ to the right (see Fig. M6.6 b).

3. The graph of the function $y = -f(x)$ is obtained from that of $y = f(x)$ by symmetric reflection with respect to the axis Ox (see Fig. M6.6 *c*).

4. The graph of the function $y = f(-x)$ is obtained from that of $y = f(x)$ by symmetric reflection with respect to the axis Oy (see Fig. M6.6 *d*).

5. The graph of the function $y = f(kx)$ for $k > 1$ is obtained from that of $y = f(x)$ by contracting the latter k times to the axis Oy, and for $0 < k < 1$ by extending the latter $1/k$ times from the axis Oy. The points at which the graph crosses the axis Oy remain unchanged (see Fig. M6.6 *e*).

6. The graph of the function $y = kf(x)$ for $k > 1$ is obtained from that of $y = f(x)$ by extending the latter k times from the axis Ox, and for $0 < k < 1$ by contracting the latter $1/k$ times to the axis Ox. The points at which the graph crosses the axis Ox remain unchanged (see Fig. M6.6*f*).

7. The graph of the function $y = |f(x)|$ is obtained from that of $y = f(x)$ by preserving the parts of the latter for which $f(x) \geq 0$ and symmetric reflection, with respect to the axis Ox, of the parts for which $f(x) < 0$ (see Fig. M6.6 *g*).

8. The graph of the inverse function $y = f^{-1}(x)$ is obtained from that of $y = f(x)$ by symmetric reflection with respect to the straight line $y = x$ (see Fig. M6.6 *h*).

M6.2.7. Approximate Solution of Equations (Root-Finding Algorithms for Continuous Functions)

► **Preliminaries.** For a vast majority of algebraic (transcendental) equations of the form

$$f(x) = 0, \qquad \text{(M6.2.7.1)}$$

where $f(x)$ is a continuous function, there are no exact formulas for the roots.

When solving the equation approximately, the first step is to bracket the roots, i.e., find sufficiently small intervals containing exactly one root each. Such an interval $[a, b]$, where the numbers a and b satisfy the condition $f(a)f(b) < 0$ (which is assumed to hold in what follows), can be found, say, graphically.

The second step is to compute successive approximations $x_n \in [a, b]$ ($n = 1, 2, \dots$) to the desired root $c = \lim\limits_{n\to\infty} x_n$, usually by one of the following methods.

► **Bisection method.** To find the root of equation (M6.2.7.1) on the interval $[a, b]$, we bisect the interval. If $f\left(\frac{a+b}{2}\right) = 0$, then $c = \frac{a+b}{2}$ is the desired root. If $f\left(\frac{a+b}{2}\right) \neq 0$, then of the two intervals $\left[a, \frac{a+b}{2}\right]$ and $\left[\frac{a+b}{2}, b\right]$ we take the one at whose endpoints the function $f(x)$ has opposite signs. Now we bisect the new, smaller interval, etc. As a result, we obtain either an exact root of equation (M6.2.7.1) at some step or an infinite sequence of nested intervals $[a_1, b_1]$, $[a_2, b_2]$, … such that $f(a_n)f(b_n) < 0$. The root is given by the formula $c = \lim\limits_{n\to\infty} a_n = \lim\limits_{n\to\infty} b_n$, and the estimate

$$0 \leq c - a_n \leq \frac{1}{2^n}(b - a)$$

is valid.

The following two methods are more efficient.

► **Regula falsi method (false position method).** Suppose that the derivatives $f'(x)$ and $f''(x)$ exist on the interval $[a, b]$ and the inequalities $f'(x) \neq 0$ and $f''(x) \neq 0$ hold for all $x \in [a, b]$.

If $f'(a)f''(a) > 0$, then we take $x_0 = a$ for the zero approximation; the subsequent approximations are given by the formulas

$$x_{n+1} = x_n - \frac{f(x_n)}{f(b) - f(x_n)}(b - x_n), \qquad n = 0,\ 1,\ \ldots$$

If $f'(a)f''(a) < 0$, then we take $x_0 = b$ for the zero approximation; the subsequent approximations are given by the formulas

$$x_{n+1} = x_n - \frac{f(x_n)}{f(a) - f(x_n)}(a - x_n), \qquad n = 0,\ 1,\ \ldots$$

The regula falsi method has the first order of local convergence as $n \to \infty$, that is,

$$|x_{n+1} - c| \le k|x_n - c|,$$

where k is a constant depending on $f(x)$ and c is the root of equation (M6.2.7.1).

The regula falsi method has a simple geometric interpretation. The straight line (secant) passing through the points $(a, f(a))$ and $(b, f(b))$ of the curve $y = f(x)$ meets the abscissa axis at the point x_1; the value x_{n+1} is the abscissa of the point where the line passing through the points $(x_0, f(x_0))$ and $(x_n, f(x_n))$ meets the x-axis (see Fig. M6.7 *a*).

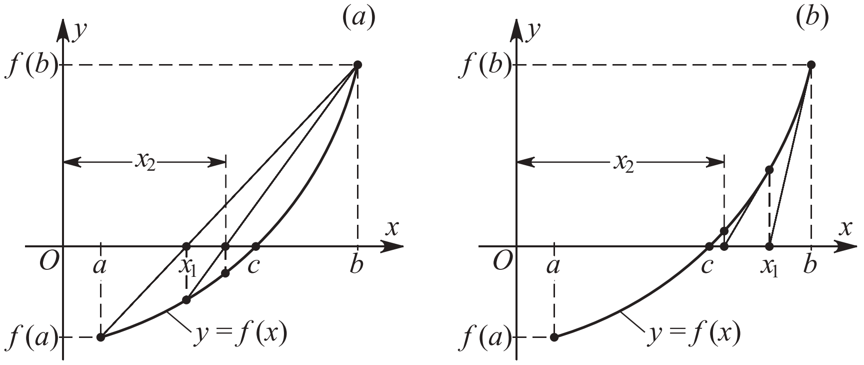

Figure M6.7. Graphical construction of successive approximations to the root of equation (M6.2.7.1) by the regula falsi method (*a*) and the Newton–Raphson method (*b*).

► **Newton–Raphson method.** Suppose that the derivatives $f'(x)$ and $f''(x)$ exist on the interval $[a, b]$ and the inequalities $f'(x) \neq 0$ and $f''(x) \neq 0$ hold for all $x \in [a, b]$.

If $f(a)f''(a) > 0$, then we take $x_0 = a$ for the zero approximation; if $f(b)f''(b) > 0$, then $x_0 = b$. The subsequent approximations are computed by the formulas

$$x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)}, \qquad n = 0,\ 1,\ \ldots$$

If the initial approximation x_0 is sufficiently close to the desired root c, then the Newton–Raphson method exhibits quadratic convergence:

$$|x_{n+1} - c| \le \frac{M}{2m}|x_n - c|^2,$$

where $M = \max\limits_{a \le x \le b} |f''(x)|$ and $m = \min\limits_{a \le x \le b} |f'(x)|$.

The Newton–Raphson method has a simple geometric interpretation. The tangent to the curve $y = f(x)$ through the point $(x_n, f(x_n))$ meets the abscissa axis at the point x_{n+1} (see Fig. M6.7 *b*).

The Newton–Raphson method has a higher order of convergence than the regula falsi method. Hence the former is more often used in practice.

M6.3. Functions of Several Variables. Partial Derivatives

M6.3.1. Point Sets. Functions. Limits and Continuity

► **Sets on the plane and in space.** The distance between two points A and B on the plane and in space can be defined as follows:

$$\rho(A,B)=\sqrt{(x_A-x_B)^2+(y_A-y_B)^2} \qquad \text{(on the plane)},$$

$$\rho(A,B)=\sqrt{(x_A-x_B)^2+(y_A-y_B)^2+(z_A-z_B)^2} \qquad \text{(in three-dimensional space)},$$

$$\rho(A,B)=\sqrt{(x_{1A}-x_{1B})^2+\cdots+(x_{nA}-x_{nB})^2} \qquad \text{(in n-dimensional space)},$$

where x_A, y_A and x_B, y_B, and x_A, y_A, z_A and x_B, y_B, z_B, and x_{1A}, $\ldots$, x_{nA} and x_{1B}, $\ldots$, x_{nB} are Cartesian coordinates of the respective points.

An *ε-neighborhood of a point* M_0 (on the plane or in space) is the set consisting of all points M (resp., on the plane or in space) such that $\rho(M,M_0)<\varepsilon$, where it is assumed that $\varepsilon>0$. An *ε-neighborhood of a set* K (on the plane or in space) is the set consisting of all points M (resp., on the plane or in space) such that $\inf\limits_{M_0\in K}\rho(M,M_0)<\varepsilon$, where it is assumed that $\varepsilon>0$.

An *interior point* of a set D is a point belonging to D, together with some neighborhood of that point. An *open set* is a set containing only interior points. A *boundary point* of a set D is a point such that any of its neighborhoods contains points both inside and outside D. A *closed set* is a set containing all its boundary points. A set D is called a *bounded set* if $\rho(A,B)<C$ for any points $A,B\in D$, where C is a constant independent of A,B. Otherwise (i.e., if there is no such constant), the set D is called *unbounded*.

► **Functions of two or three variables.** A (numerical) *function* on a set D is, by definition, a relation that sets up a correspondence between each point $M\in D$ and a unique numerical value. If D is a plane set, then each point $M\in D$ is determined by two coordinates x, y, and a function $z=f(M)=f(x,y)$ is called a *function of two variables*. If D belongs to a three-dimensional space, then one speaks of a *function of three variables*. The set D on which the function is defined is called the *domain* of the function. For instance, the function $z=\sqrt{1-x^2-y^2}$ is defined on the closed circle $x^2+y^2\le 1$, which is its domain.

The *graph* of a function $z=f(x,y)$ is the surface formed by the points $(x,y,f(x,y))$ in three-dimensional space. For instance, the graph of the function $z=ax+by+c$ is a plane, and the graph of the function $z=\sqrt{1-x^2-y^2}$ is a semisphere.

A *level line* of a function $z=f(x,y)$ is a line on the plane x, y with the following property: the function takes one and the same value $z=c$ at all points of that line. Thus, the equation of a level line has the form $f(x,y)=c$. A *level surface* of a function $u=f(x,y,z)$ is a surface on which the function takes a constant value, $u=c$; the equation of a level surface has the form $f(x,y,z)=c$.

A function $f(M)$ is called *bounded* on a set D if there is a constant C such that $|f(M)|\le C$ for all $M\in D$.

► **Limit of a function at a point and its continuity.** Let M be a point that comes infinitely close to some point M_0, i.e., $\rho=\rho(M_0,M)\to 0$. It is possible that the values $f(M)$ come close to some constant b.

One says that b is the *limit of the function* $f(M)$ at the point M_0 if for any (arbitrarily small) $\varepsilon>0$, there is $\delta>0$ such that for all points M belonging to the domain of the function and satisfying the inequality $0<\rho(M_0,M)<\delta$, we have $|f(M)-b|<\varepsilon$. In this case, one writes $\lim\limits_{\rho(M,M_0)\to 0}f(M)=b$.

A function $f(M)$ is called *continuous* at a point M_0 if $\lim\limits_{\rho(M,M_0)\to 0} f(M) = f(M_0)$. A function is called *continuous on a set* D if it is continuous at each point of D. Any continuous function $f(M)$ on a closed bounded set is bounded on that set and attains its smallest and its largest values on that set.

M6.3.2. Differentiation of Functions of Several Variables

For the sake of brevity, we consider the case of a function of two variables. However, all statements can be easily extended to the case of n variables.

► **Total and partial increments of a function. Partial derivatives.** A *total increment* of a function $z = f(x, y)$ at a point (x, y) is

$$\Delta z = f(x + \Delta x, y + \Delta y) - f(x, y),$$

where Δx, Δy are increments of the independent variables. *Partial increments* in x and in y are, respectively,

$$\Delta_x z = f(x + \Delta x, y) - f(x, y),$$
$$\Delta_y z = f(x, y + \Delta y) - f(x, y).$$

Partial derivatives of a function z with respect to x and to y at a point (x, y) are defined as follows:

$$\frac{\partial z}{\partial x} = \lim_{\Delta x\to 0} \frac{\Delta_x z}{\Delta x}, \qquad \frac{\partial z}{\partial y} = \lim_{\Delta y\to 0} \frac{\Delta_y z}{\Delta y}$$

(provided that these limits exist). Partial derivatives are also denoted by z_x and z_y, $\partial_x z$ and $\partial_y z$, or $f_x(x, y)$ and $f_y(x, y)$.

► **Differentiable functions. Differential.** A function $z = f(x, y)$ is called *differentiable* at a point (x, y) if its increment at that point can be represented in the form

$$\Delta z = A(x, y)\Delta x + B(x, y)\Delta y + o(\rho), \qquad \rho = \sqrt{(\Delta x)^2 + (\Delta y)^2},$$

where $o(\rho)$ is a quantity of a higher order of smallness compared with ρ as $\rho \to 0$ (i.e., $o(\rho)/\rho \to 0$ as $\rho \to 0$). In this case, there exist partial derivatives at the point (x, y), and $z_x = A(x, y)$, $z_y = B(x, y)$.

A function that has continuous partial derivatives at a point (x, y) is differentiable at that point.

The *differential* dz *of a function* $z = f(x, y)$ is defined as follows:

$$dz = f_x(x, y)\Delta x + f_y(x, y)\Delta y.$$

Taking the differentials dx and dy of the independent variables equal to Δx and Δy, respectively, one can also write $dz = f_x(x, y)\,dx + f_y(x, y)\,dy$.

The relation $\Delta z = dz + o(\rho)$ for small Δx and Δy is widely used for approximate calculations, in particular, for finding errors in numerical calculations of values of a function.

Example 1. Suppose that the values of the arguments of the function $z = x^2y^5$ are known with the error $x = 2 \pm 0.01$, $y = 1 \pm 0.01$. Let us calculate the approximate value of the function.

We find the increment of the function z at the point $x = 2$, $y = 1$ for $\Delta x = \Delta y = 0.01$, using the formula $\Delta z \approx dz = 2 \cdot 2 \cdot 1^5 \cdot 0.01 + 5 \cdot 2^2 \cdot 1^4 \cdot 0.01 = 0.24$. Therefore, we can accept the approximation $z = 4 \pm 0.24$.

If a function $z = f(x, y)$ is differentiable at a point (x_0, y_0), then

$$f(x, y) = f(x_0, y_0) + f_x(x_0, y_0)(x - x_0) + f_y(x_0, y_0)(y - y_0) + o(\rho).$$

Hence, for small ρ (i.e., for $x \approx x_0$, $y \approx y_0$), we obtain the approximate formula

$$f(x, y) \approx f(x_0, y_0) + f_x(x_0, y_0)(x - x_0) + f_y(x_0, y_0)(y - y_0).$$

The replacement of a function by this linear expression near a given point is called *linearization*.

► **Composite function.** Consider a function $z = f(x, y)$ and let $x = x(u, v)$, $y = y(u, v)$. Suppose that for $(u, v) \in D$, the functions $x(u, v)$, $y(u, v)$ take values for which the function $z = f(x, y)$ is defined. In this way, one defines a *composite function* on the set D, namely, $z(u, v) = f\bigl(x(u, v), y(u, v)\bigr)$. In this situation, $f(x, y)$ is called the outer function and $x(u, v)$, $y(u, v)$ are called the inner functions.

Partial derivatives of a composite function are expressed by

$$\frac{\partial z}{\partial u} = \frac{\partial f}{\partial x}\frac{\partial x}{\partial u} + \frac{\partial f}{\partial y}\frac{\partial y}{\partial u},$$
$$\frac{\partial z}{\partial v} = \frac{\partial f}{\partial x}\frac{\partial x}{\partial v} + \frac{\partial f}{\partial y}\frac{\partial y}{\partial v}.$$

For $z = z(t, x, y)$, let $x = x(t)$, $y = y(t)$. Thus, z is actually a function of only one variable t. The derivative $\frac{dz}{dt}$ is calculated by

$$\frac{dz}{dt} = \frac{\partial z}{\partial t} + \frac{\partial z}{\partial x}\frac{dx}{dt} + \frac{\partial z}{\partial y}\frac{dy}{dt}.$$

This derivative, in contrast to the partial derivative $\frac{\partial z}{\partial t}$, is called a *total derivative*.

► **Second partial derivatives and second differentials.** The *second partial derivatives* of a function $z = f(x, y)$ are defined as the derivatives of its first partial derivatives and are denoted as follows:

$$\frac{\partial^2 z}{\partial x^2} = z_{xx} \equiv (z_x)_x, \qquad \frac{\partial^2 z}{\partial x\,\partial y} = z_{xy} \equiv (z_x)_y,$$
$$\frac{\partial^2 z}{\partial y\,\partial x} = z_{yx} \equiv (z_y)_x, \qquad \frac{\partial^2 z}{\partial y^2} = z_{yy} \equiv (z_y)_y.$$

The derivatives z_{xy} and z_{yx} are called *mixed derivatives*. If the mixed derivatives are continuous at some point, then they coincide at that point, $z_{xy} = z_{yx}$.

In a similar way, one defines higher-order partial derivatives.

The *second differential* of a function $z = f(x, y)$ is the expression

$$d^2 z = d(dz) = (dz)_x \Delta x + (dz)_y \Delta y = z_{xx}(\Delta x)^2 + 2z_{xy}\Delta x \Delta y + z_{yy}(\Delta y)^2.$$

In a similar way, one defines $d^3 z$, $d^4 z$, etc.

► **Implicit functions and their differentiation.** Consider the equation $F(x, y) = 0$ with a solution (x_0, y_0). Suppose that the derivative $F_y(x, y)$ is continuous in a neighborhood of the point (x_0, y_0) and $F_y(x, y) \neq 0$ in that neighborhood. Then the equation $F(x, y) = 0$ defines a continuous function $y = y(x)$ (called an *implicit function*) of the variable x in a neighborhood of the point x_0. Moreover, if in a neighborhood of (x_0, y_0) there exists a continuous derivative F_x, then the implicit function $y = y(x)$ has a continuous derivative expressed by $\dfrac{dy}{dx} = -\dfrac{F_x}{F_y}$.

Consider the equation $F(x, y, z) = 0$ that establishes a relation between the variables x, y, z. If $F(x_0, y_0, z_0) = 0$ and in a neighborhood of the point (x_0, y_0, z_0) there exist continuous partial derivatives F_x, F_y, F_z such that $F_z(x_0, y_0, z_0) \neq 0$, then equation $F(x, y, z) = 0$, in a neighborhood of (x_0, y_0), has a unique solution $z = \varphi(x, y)$ such that $\varphi(x_0, y_0) = z_0$;

moreover, the function $z = \varphi(x, y)$ is continuous and has continuous partial derivatives expressed by

$$\frac{\partial z}{\partial x} = -\frac{F_x}{F_z}, \qquad \frac{\partial z}{\partial y} = -\frac{F_y}{F_z}.$$

Example 2. For the equation $x \sin y + z + e^z = 0$ we have $F_z = 1 + e^z \neq 0$. Therefore, this equation defines an implicit function $z = \varphi(x, y)$ on the entire plane, and its derivatives have the form $\dfrac{\partial z}{\partial x} = -\dfrac{\sin y}{1 + e^z}$, $\dfrac{\partial z}{\partial y} = -\dfrac{x \cos y}{1 + e^z}$.

► Jacobian. Dependent and independent functions. Invertible transformations.

1°. Two functions $f(x, y)$ and $g(x, y)$ are called *dependent* if there is a function $\Phi(z)$ such that $g(x, y) = \Phi(f(x, y))$; otherwise, the functions $f(x, y)$ and $g(x, y)$ are called *independent*.

The *Jacobian* is the determinant of the matrix whose elements are the first partial derivatives of the functions $f(x, y)$ and $g(x, y)$:

$$\frac{\partial(f, g)}{\partial(x, y)} \equiv \begin{vmatrix} \frac{\partial f}{\partial x} & \frac{\partial f}{\partial y} \\ \frac{\partial g}{\partial x} & \frac{\partial g}{\partial y} \end{vmatrix}. \tag{M6.3.2.1}$$

1) If the Jacobian (M6.3.2.1) in a domain D is identically equal to zero, then the functions $f(x, y)$ and $g(x, y)$ are dependent in D.

2) If the Jacobian (M6.3.2.1) is nonzero in D, then the functions $f(x, y)$ and $g(x, y)$ are independent in D.

2°. Functions $f_k(x_1, x_2, \dots, x_n)$, $k = 1, 2, \dots, n$, are called dependent in a domain D if there is a function $\Phi(z_1, z_2, \dots, z_n)$ such that

$$\Phi\bigl(f_1(x_1, x_2, \dots, x_n), f_2(x_1, x_2, \dots, x_n), \dots, f_n(x_1, x_2, \dots, x_n)\bigr) = 0 \qquad \text{(in } D\text{);}$$

otherwise, these functions are called independent.

The *Jacobian* is the determinant of the matrix whose elements are the first partial derivatives:

$$\frac{\partial(f_1, f_2, \dots, f_n)}{\partial(x_1, x_2, \dots, x_n)} \equiv \det\left(\frac{\partial f_i}{\partial x_j}\right). \tag{M6.3.2.2}$$

The functions $f_k(x_1, x_2, \dots, x_n)$ are dependent in a domain D if the Jacobian (M6.3.2.2) is identically equal to zero in D. The functions $f_k(x_1, x_2, \dots, x_n)$ are independent in D if the Jacobian (M6.3.2.2) does not vanish in D.

3°. Consider the transformation

$$y_k = f_k(x_1, x_2, \dots, x_n), \qquad k = 1, 2, \dots, n. \tag{M6.3.2.3}$$

Suppose that the functions f_k are continuously differentiable and the Jacobian (M6.3.2.2) differs from zero at a point $(x_1^\circ, x_2^\circ, \dots, x_n^\circ)$. Then, in a sufficiently small neighborhood of this point, equations (M6.3.2.3) specify a one-to-one correspondence between the points of that neighborhood and the set of points $(y_1, y_2, \dots, y_n)$ consisting of the values of the functions (M6.3.2.3) in the corresponding neighborhood of the point $(y_1^\circ, y_2^\circ, \dots, y_n^\circ)$. This means that the system (M6.3.2.3) is locally solvable in a neighborhood of the point $(x_1^\circ, x_2^\circ, \dots, x_n^\circ)$, i.e., the following representation holds:

$$x_k = g_k(y_1, y_2, \dots, y_n), \qquad k = 1, 2, \dots, n,$$

where g_k are continuously differentiable functions in the corresponding neighborhood of the point $(y_1^\circ, y_2^\circ, \dots, y_n^\circ)$.

M6.3.3. Directional Derivative. Gradient. Geometrical Applications

► **Directional derivative.** One says that a *scalar field* is defined in a domain D if any point $M(x,y)$ of that domain is associated with a certain value $z = f(M) = f(x,y)$. Thus, a thermal field and a pressure field are examples of scalar fields. A *level line* of a scalar field is a level line of the function that specifies the field (see Subsection M6.3.1). Thus, isothermal and isobaric curves are, respectively, level lines of thermal and pressure fields.

In order to examine the behavior of a field $z = f(x,y)$ at a point $M_0(x_0,y_0)$ in the direction of a vector $\mathbf{a} = \{a_1, a_2\}$, one should construct a straight line passing through M_0 in the direction of the vector **a** (this line can be specified by the parametric equations $x = x_0 + a_1 t$, $y = y_0 + a_2 t$) and study the function $z(t) = f(x_0 + a_1 t,\ y_0 + a_2 t)$. The derivative of the function $z(t)$ at the point M_0 (i.e., for $t = 0$) characterizes the change rate of the field at that point in the direction **a**. Dividing $z'(0)$ by $|\mathbf{a}| = \sqrt{a_1^2 + a_2^2}$, we obtain the so-called *derivative in the direction* **a** of the given field at the given point:

$$\frac{\partial f}{\partial \mathbf{a}} = \frac{1}{|\mathbf{a}|}\bigl[\,a_1 f_x(x_0,y_0) + a_2 f_y(x_0,y_0)\bigr].$$

The *gradient* of the scalar field $z = f(x,y)$ is, by definition, the vector-valued function

$$\operatorname{grad} f = f_x(x,y)\mathbf{i} + f_y(x,y)\mathbf{j},$$

where **i** and **j** are unit vectors along the coordinate axes x and y. At each point, the gradient of a scalar field is orthogonal to the level line passing through that point. The gradient indicates the direction of maximal growth of the field. In terms of the gradient, the directional derivative can be expressed as follows:

$$\frac{\partial f}{\partial \mathbf{a}} = \frac{\mathbf{a}}{|\mathbf{a}|}\operatorname{grad} f.$$

The gradient is also denoted by $\nabla f = \operatorname{grad} f$.

Remark. The above facts for a plane scalar field obviously can be extended to the case of a spatial scalar field.

► **Geometrical applications of the theory of functions of several variables.**

1. The *equation of the tangent plane* to the surface $z = f(x,y)$ at a point (x_0, y_0, z_0), where $z_0 = f(x_0,y_0)$, has the form

$$z = f(x_0,y_0) + f_x(x_0,y_0)(x - x_0) + f_y(x_0,y_0)(y - y_0).$$

The vector of the normal to the surface at that point is

$$\mathbf{n} = \bigl\{-f_x(x_0,y_0),\ -f_y(x_0,y_0),\ 1\bigr\}.$$

2. If a surface is defined by the equation $\Phi(x,y,z) = 0$, then the equation of its tangent plane at the point (x_0,y_0,z_0) has the form

$$\Phi_x(x_0,y_0,z_0)(x - x_0) + \Phi_y(x_0,y_0,z_0)(y - y_0) + \Phi_z(x_0,y_0,z_0)(z - z_0) = 0.$$

A normal vector to the surface at this point is

$$\mathbf{n} = \bigl\{\Phi_x(x_0,y_0,z_0),\ \Phi_y(x_0,y_0,z_0),\ \Phi_z(x_0,y_0,z_0)\bigr\}.$$

3. Consider a surface defined by the parametric equations

$$x = x(u,v), \quad y = y(u,v), \quad z = z(u,v)$$

or, in vector form, $\mathbf{r} = \mathbf{r}(u,v)$, where $\mathbf{r} = \{x,y,z\}$, and let $M_0\bigl(x(u_0,v_0),\ y(u_0,v_0),\ z(u_0,v_0)\bigr)$ be the point of the surface corresponding to the parameter values $u = u_0$, $v = v_0$. Then the vector of the normal to the surface at the point M_0 can be expressed by

$$\mathbf{n}(u,v) = \frac{\partial \mathbf{r}}{\partial u} \times \frac{\partial \mathbf{r}}{\partial v} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ x_u & y_u & z_u \\ x_v & y_v & z_v \end{vmatrix},$$

where all partial derivatives are calculated at the point M_0.

M6.3.4. Extremal Points of Functions of Several Variables

► **Conditions of extremum of a function of two variables.**

1°. *Points of minimum, maximum, or extremum.* A point (x_0, y_0) is called a *point of local minimum* (resp., *maximum*) of a function $z = f(x, y)$ if there is a neighborhood of (x_0, y_0) in which the function is defined and satisfies the inequality $f(x, y) > f(x_0, y_0)$ (resp., $f(x, y) < f(x_0, y_0)$). Points of maximum or minimum are called *points of extremum.*

2°. A *necessary condition of extremum.* If a function has the first partial derivatives at a point of its extremum, these derivatives must vanish at that point. It follows that in order to find points of extremum of such a function $z = f(x, y)$, one should find solutions of the system of equations

$$f_x(x, y) = 0, \quad f_y(x, y) = 0.$$

The points whose coordinates satisfy this system are called *stationary points.* Any point of extremum of a differentiable function is its stationary point, but not every stationary point is a point of its extremum.

3°. *Sufficient conditions of extremum* are used for the identification of points of extremum among stationary points. Some conditions of this type are given below.

Suppose that the function $z = f(x, y)$ has continuous second derivatives at a stationary point. Let us calculate the following quantity at this point:

$$\Delta = f_{xx} f_{yy} - f_{xy}^2.$$

The following statements hold:

1) If $\Delta > 0$, $f_{xx} > 0$, then the stationary point is a point of local minimum;
2) If $\Delta > 0$, $f_{xx} < 0$, then the stationary point is a point of local maximum;
3) If $\Delta < 0$, then the stationary point cannot be a point of extremum.

In the degenerate case, $\Delta = 0$, a more delicate analysis of a stationary point is required. In this case, a stationary point may happen to be a point of extremum and may not.

Remark. In order to find points of extremum, one should check not only stationary points, but also points at which the first derivatives do not exist or are infinite.

4°. *The smallest and the largest values of a function.* Let $f(x, y)$ be a continuous function in a closed bounded domain D. Any such function takes its smallest and its largest values in D.

If the function has partial derivatives in D, except at some points, then the following method can be helpful for determining the coordinates of the points $(x_{\min}, y_{\min})$ and $(x_{\max}, y_{\max})$ at which the function attains its minimum and maximum, respectively. One should find all internal stationary points and all points at which the derivatives are infinite or do not exist. Then one should calculate the values of the function at these points and compare these with its values at the boundary points of the domain, and then choose the largest and the smallest values.

► **Extremal points of functions of three variables.** For functions of three variables, points of extremum are defined in exactly the same way as for functions of two variables. Let us briefly describe the scheme of finding extremal points of a function $u = \Phi(x, y, z)$. Finding solutions of the system of equations

$$\Phi_x(x, y, z) = 0, \quad \Phi_y(x, y, z) = 0, \quad \Phi_z(x, y, z) = 0,$$

we determine stationary points. For each stationary point, we calculate the values of

$$\Delta_1 = \Phi_{xx}, \quad \Delta_2 = \begin{vmatrix} \Phi_{xx} & \Phi_{xy} \\ \Phi_{xy} & \Phi_{yy} \end{vmatrix}, \quad \Delta_3 = \begin{vmatrix} \Phi_{xx} & \Phi_{xy} & \Phi_{xz} \\ \Phi_{xy} & \Phi_{yy} & \Phi_{yz} \\ \Phi_{xz} & \Phi_{yz} & \Phi_{zz} \end{vmatrix}.$$

The following statements hold:

1) If $\Delta_1 > 0$, $\Delta_2 > 0$, $\Delta_3 > 0$, then the stationary point is a point of local minimum;
2) If $\Delta_1 < 0$, $\Delta_2 > 0$, $\Delta_3 < 0$, then the stationary point is a point of local maximum.

► **Conditional extremum of a function of two variables. Lagrange function.** A point (x_0, y_0) is called a *point of conditional or constrained minimum* (resp., *maximum*) of a function

$$z = f(x, y) \qquad \text{(M6.3.4.1)}$$

under the additional condition*

$$\varphi(x, y) = 0 \qquad \text{(M6.3.4.2)}$$

if there is a neighborhood of the point (x_0, y_0) in which $f(x, y) > f(x_0, y_0)$ (resp., $f(x, y) < f(x_0, y_0)$) for all points (x, y) satisfying the condition (M6.3.4.2).

For the determination of points of conditional extremum, it is common to use the *Lagrange function*

$$\Phi(x, y, \lambda) = f(x, y) + \lambda\varphi(x, y),$$

where λ is the so-called *Lagrange multiplier*. Solving the system of three equations (the last equation coincides with the condition (M6.3.4.2))

$$\frac{\partial\Phi}{\partial x} = 0, \quad \frac{\partial\Phi}{\partial y} = 0, \quad \frac{\partial\Phi}{\partial\lambda} = 0,$$

one finds stationary points of the Lagrange function (and also the value of the multiplier λ). The stationary points may happen to be points of extremum. The above system yields only necessary conditions of extremum, but these conditions may be insufficient; it may happen that there is no extremum at some stationary points. However, with the help of other properties of the function under consideration, it is often possible to establish the character of a critical point.

Example 1. Let us find an extremum of the function

$$z = x^n y, \qquad \text{(M6.3.4.3)}$$

under the condition

$$x + y = a \qquad (a > 0,\ n > 0,\ x \ge 0,\ y \ge 0). \qquad \text{(M6.3.4.4)}$$

Taking $\varphi(x, y) = x + y - a$, we construct the Lagrange function

$$\Phi(x, y, \lambda) = x^n y + \lambda(x + y - a).$$

Solving the system of equations

$$\begin{aligned} \Phi_x &\equiv nx^{n-1}y + \lambda = 0, \\ \Phi_y &\equiv x^n + \lambda = 0, \\ \Phi_\lambda &\equiv x + y - a = 0, \end{aligned}$$

we find the coordinates of a unique stationary point,

$$x_\circ = \frac{an}{n+1}, \quad y_\circ = \frac{a}{n+1}, \quad \lambda_\circ = -\left(\frac{an}{n+1}\right)^n,$$

which corresponds to the conditional maximum of the given function, $z_{\max} = \dfrac{a^{n+1}n^n}{(n+1)^{n+1}}$.

---

* This condition is also called a *constraint*.

Remark. In order to find points of conditional extremum of functions of two variables, it is often convenient to express the variable y through x (or vice versa) from the additional equation (M6.3.4.2) and substitute the resulting expression into the right-hand side of (M6.3.4.1). In this way, the original problem is reduced to the problem of extremum for a function of a single variable.

Example 2. Consider again the extremum problem of Example 1 for the function of two variables (M6.3.4.3) with the constraint (M6.3.4.4). After the elimination of the variable y from (M6.3.4.3)–(M6.3.4.4), the original problem is reduced to the extremum problem for the function $z = x^n(a - x)$ of one variable.

► **Conditional extrema of functions of several variables.** Consider a function $u = f(x_1, \dots, x_n)$ of n variables under the condition that x_1, …, x_n satisfy m equations ($m < n$):

$$\begin{cases} \varphi_1(x_1, \dots, x_n) = 0, \\ \varphi_2(x_1, \dots, x_n) = 0, \\ \dots\dots\dots\dots\dots\dots, \\ \varphi_m(x_1, \dots, x_n) = 0. \end{cases}$$

In order to find the values of x_1, …, x_n for which f may have a conditional maximum or minimum, one should construct the Lagrange function

$$\Phi(x_1, \dots, x_n; \lambda_1, \dots, \lambda_m) = f + \lambda_1\varphi_1 + \lambda_2\varphi_2 + \dots + \lambda_m\varphi_m$$

and equate to zero its first partial derivatives with respect to the variables $x_1, \dots, x_n$ and the parameters $\lambda_1, \dots, \lambda_m$. From the resulting $n+m$ equations, one finds $x_1, \dots, x_n$ (and also the values of the unknown Lagrange multipliers $\lambda_1, \dots, \lambda_m$). As in the case of functions of two variables, the question whether the given function has points of conditional extremum can be answered on the basis of additional investigation.

Example 3. Consider the problem of finding the shortest distance from the point (x_0, y_0, z_0) to the plane

$$Ax + By + Cz + D = 0. \qquad \text{(M6.3.4.5)}$$

The squared distance between the points (x_0, y_0, z_0) and (x, y, z) is equal to

$$R^2 = (x - x_0)^2 + (y - y_0)^2 + (z - z_0)^2. \qquad \text{(M6.3.4.6)}$$

In our case, the coordinates (x, y, z) should satisfy equation (M6.3.4.5) (this point should belong to the plane). Thus, our problem is to find the minimum of the expression (M6.3.4.6) under the condition (M6.3.4.5). The Lagrange function has the form

$$\Phi = (x - x_0)^2 + (y - y_0)^2 + (z - z_0)^2 + \lambda(Ax + By + Cz + D).$$

Equating to zero the derivatives of Φ with respect to x, y, z, and λ, we obtain the following system of algebraic equations:

$$2(x - x_0) + A\lambda = 0, \quad 2(y - y_0) + B\lambda = 0, \quad 2(z - z_0) + C\lambda = 0, \quad Ax + By + Cz + D = 0.$$

Its solution has the form

$$x = x_0 - \frac{1}{2}A\lambda, \quad y = y_0 - \frac{1}{2}B\lambda, \quad z = z_0 - \frac{1}{2}C\lambda, \quad \lambda = \frac{2(Ax_0 + By_0 + Cz_0 + D)}{A^2 + B^2 + C^2}. \qquad \text{(M6.3.4.7)}$$

Thus we have a unique answer, and since the distance between a given point and the plane can be realized at a single point (x, y, z), the values obtained should correspond to that distance. Substituting the values (M6.3.4.7) into (M6.3.4.6), we find the squared distance

$$R^2 = \frac{(Ax_0 + By_0 + Cz_0 + D)^2}{A^2 + B^2 + C^2}.$$

M6.3.5. Differential Operators of the Field Theory

► **Hamilton's operator and first-order differential operators.** Hamilton's operator, commonly known as the *nabla vector operator* or the *gradient operator*, is the symbolic vector

$$\nabla = \mathbf{i}\,\frac{\partial}{\partial x} + \mathbf{j}\,\frac{\partial}{\partial y} + \mathbf{k}\,\frac{\partial}{\partial z}.$$

This vector can be used for expressing the following differential operators:

1) gradient of a scalar function $u(x,y,z)$:

$$\operatorname{grad} u = \mathbf{i}\,\frac{\partial u}{\partial x} + \mathbf{j}\,\frac{\partial u}{\partial y} + \mathbf{k}\,\frac{\partial u}{\partial z} = \nabla u;$$

2) divergence of a vector field $\mathbf{a} = P\,\mathbf{i} + Q\,\mathbf{j} + R\,\mathbf{k}$:

$$\operatorname{div} \mathbf{a} = \frac{\partial P}{\partial x} + \frac{\partial Q}{\partial y} + \frac{\partial R}{\partial z} = \nabla \cdot \mathbf{a}$$

(scalar product of the nabla vector and the vector **a**);

3) rotation of a vector field $\mathbf{a} = P\,\mathbf{i} + Q\,\mathbf{j} + R\,\mathbf{k}$:

$$\operatorname{curl} \mathbf{a} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ P & Q & R \end{vmatrix} = \nabla \times \mathbf{a}$$

(vector product of the nabla vector and the vector **a**).

Each scalar field $u(x,y,z)$ generates a vector field $\operatorname{grad} u$. A vector field $\mathbf{a}(x,y,z)$ generates two fields: the scalar field div **a** and the vector field curl **a**.

► **Second-order differential operators.** The following differential identities hold:

$$\begin{aligned} &1)\quad \operatorname{curl}\operatorname{grad} u = \mathbf{0} \quad \text{or} \quad (\nabla \times \nabla)\,u = \mathbf{0},\\ &2)\quad \operatorname{div}\operatorname{curl} \mathbf{a} = 0 \quad \text{or} \quad \nabla \cdot (\nabla \times \mathbf{a}) = 0. \end{aligned}$$

The following differential relations hold:

$$\begin{aligned} &1)\quad \operatorname{div}\operatorname{grad} u = \Delta u = \frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} + \frac{\partial^2 u}{\partial z^2},\\ &2)\quad \operatorname{curl}\operatorname{curl} \mathbf{a} = \operatorname{grad}\operatorname{div} \mathbf{a} - \Delta \mathbf{a}, \end{aligned}$$

where Δ is the *Laplace operator*, $\Delta u = \nabla \cdot (\nabla u) = \nabla^2 u$.

Chapter M7
Integrals

M7.1. Indefinite Integral

M7.1.1. Antiderivative. Indefinite Integral and Its Properties

► **Antiderivative.** An *antiderivative* (or *primitive function*) of a given function $f(x)$ on an interval (a, b) is a differentiable function $F(x)$ such that its derivative is equal to $f(x)$ for all $x \in (a, b)$:

$$F'(x) = f(x).$$

Example 1. Let $f(x) = 2x$. Then the functions $F(x) = x^2$ and $F_1(x) = x^2 - 1$ are antiderivatives of $f(x)$, since $(x^2)' = 2x$ and $(x^2 - 1)' = 2x$.

THEOREM. *Any function $f(x)$ continuous on an interval (a, b) has infinitely many continuous antiderivatives on (a, b). If $F(x)$ is one of them, then any other antiderivative has the form $F(x) + C$, where C is a constant.*

► **Indefinite integral.** The *indefinite integral* of a function $f(x)$ is the set, $F(x) + C$, of all its antiderivatives. This fact is written as

$$\int f(x)\,dx = F(x) + C.$$

Here, $f(x)$ is called the *integrand* (or the *integrand function*). The process of finding an integral is called integration. The differential dx indicates that the integration is carried out with respect to x.

Example 2. $\int 6x^2\,dx = 2x^3 + C$, since $(2x^3)' = 6x^2$.

► **Most important corollaries of the definition of the indefinite integral.** *Differentiation is the inverse of integration*:

$$\frac{d}{dx}\left(\int f(x)\,dx\right) = f(x).$$

Integration is the inverse of differentiation:*

$$\int f'(x)\,dx = f(x) + C.$$

The latter formula serves to make up tables of indefinite integrals. The procedure is often reversed here: an integral is first given in explicit form (i.e., the function $f(x)$ on the right-hand side is prescribed), and then the integrand is obtained by differentiation.

---

* Integration recovers the function from its derivative, to an additive constant.

M7.1.2. Table of Basic Integrals. Properties of the Indefinite Integral. Examples of Integration

► **Table of basic integrals.** Listed below are most common indefinite integrals, which are important for the integration of more complicated expressions:

$$\int x^a\,dx = \frac{x^{a+1}}{a+1} + C \quad (a \neq -1), \qquad \int \frac{dx}{x} = \ln|x| + C,$$

$$\int \frac{dx}{x^2+a^2} = \frac{1}{a}\arctan\frac{x}{a} + C, \qquad \int \frac{dx}{x^2-a^2} = \frac{1}{2a}\ln\left|\frac{x-a}{x+a}\right| + C,$$

$$\int \frac{dx}{\sqrt{a^2-x^2}} = \arcsin\frac{x}{a} + C, \qquad \int \frac{dx}{\sqrt{x^2+a}} = \ln\left|x+\sqrt{x^2+a}\,\right| + C,$$

$$\int e^x\,dx = e^x + C, \qquad \int a^x\,dx = \frac{a^x}{\ln a} + C,$$

$$\int \ln x\,dx = x\ln x - x + C, \qquad \int \ln ax\,dx = x\ln ax - x + C,$$

$$\int \sin x\,dx = -\cos x + C, \qquad \int \cos x\,dx = \sin x + C,$$

$$\int \tan x\,dx = -\ln|\cos x| + C, \qquad \int \cot x\,dx = \ln|\sin x| + C,$$

$$\int \frac{dx}{\sin x} = \ln\left|\tan\frac{x}{2}\right| + C, \qquad \int \frac{dx}{\cos x} = \ln\left|\tan\left(\frac{x}{2}+\frac{\pi}{4}\right)\right| + C,$$

$$\int \frac{dx}{\sin^2 x} = -\cot x + C, \qquad \int \frac{dx}{\cos^2 x} = \tan x + C,$$

$$\int \arcsin x\,dx = x\arcsin x + \sqrt{1-x^2} + C, \qquad \int \arccos x\,dx = x\arccos x - \sqrt{1-x^2} + C,$$

$$\int \arctan x\,dx = x\arctan x - \frac{1}{2}\ln(1+x^2) + C, \qquad \int \operatorname{arccot} x\,dx = x\operatorname{arccot} x + \frac{1}{2}\ln(1+x^2) + C,$$

$$\int \sinh x\,dx = \cosh x + C, \qquad \int \cosh x\,dx = \sinh x + C,$$

$$\int \tanh x\,dx = \ln\cosh x + C, \qquad \int \coth x\,dx = \ln|\sinh x| + C,$$

$$\int \frac{dx}{\sinh x} = \ln\left|\tanh\frac{x}{2}\right| + C, \qquad \int \frac{dx}{\cosh x} = 2\arctan e^x + C,$$

$$\int \frac{dx}{\sinh^2 x} = -\coth x + C, \qquad \int \frac{dx}{\cosh^2 x} = \tanh x + C,$$

$$\int \operatorname{arcsinh} x\,dx = x\operatorname{arcsinh} x - \sqrt{1+x^2} + C, \qquad \int \operatorname{arccosh} x\,dx = x\operatorname{arccosh} x - \sqrt{x^2-1} + C,$$

$$\int \operatorname{arctanh} x\,dx = x\operatorname{arctanh} x + \frac{1}{2}\ln(1-x^2) + C, \qquad \int \operatorname{arccoth} x\,dx = x\operatorname{arccoth} x + \frac{1}{2}\ln(x^2-1) + C,$$

where C is an arbitrary constant.

A more extensive table of indefinite integrals can be found in Section S1.1.

► **Properties of the indefinite integral.**

1. *A constant factor can be taken outside the integral sign*:

$$\int af(x)\,dx = a\int f(x)\,dx \qquad (a = \text{const}).$$

2. *Integral of the sum or difference of functions* (*additivity*):

$$\int [f(x) \pm g(x)]\,dx = \int f(x)\,dx \pm \int g(x)\,dx.$$

3. *Integration by parts*:

$$\int f(x)g'(x)\,dx = f(x)g(x) - \int f'(x)g(x)\,dx.$$

4. *Repeated integration by parts* (generalization of the previous formula):

$$\int f(x)g^{(n+1)}(x)\,dx = f(x)g^{(n)}(x) - f'(x)g^{(n-1)}(x) + \cdots + (-1)^n f^{(n)}(x)g(x) + (-1)^{n+1}\int f^{(n+1)}(x)g(x)\,dx, \qquad n = 0,\ 1,\ \ldots$$

5. *Change of variable* (*integration by substitution*):

$$\int f(x)\,dx = \int f(\varphi(t))\,\varphi'(t)\,dt, \qquad x = \varphi(t).$$

On computing the integral using the change of variable $x = \varphi(t)$, one should rewrite the resulting expression in terms of the original variable x using the inverse substitution $t = \varphi^{-1}(x)$.

► Examples of direct integration of elementary functions.

1°. With simple algebraic manipulation and the properties listed above, the integration may often be reduced to tabulated integrals.

Example 1. $\displaystyle\int \frac{2x-1}{\sqrt{x}}\,dx = \int\left(2\sqrt{x} - \frac{1}{\sqrt{x}}\right)dx = 2\int x^{1/2}\,dx - \int x^{-1/2}\,dx = \frac{4}{3}x^{3/2} - 2x^{1/2} + C.$

2°. Tabulated integrals can also be used where any function $\varphi(x)$ appears in place of x; for example,

$$\int e^x\,dx = e^x + C \quad\Longrightarrow\quad \int e^{\varphi(x)}\,d\varphi(x) = e^{\varphi(x)} + C;$$

$$\int \frac{dx}{x} = \ln|x| + C \quad\Longrightarrow\quad \int \frac{d\sin x}{\sin x} = \ln|\sin x| + C.$$

The reduction of an integral to a tabulated one may often be achieved by taking some function inside the differential sign.

Example 2. $\displaystyle\int \tan x\,dx = \int \frac{\sin x\,dx}{\cos x} = \int \frac{-d\cos x}{\cos x} = -\int \frac{d\cos x}{\cos x} = -\ln|\cos x| + C.$

3°. Integrals of the form $\displaystyle\int \frac{dx}{ax^2+bx+c}, \int \frac{dx}{\sqrt{ax^2+bx+c}}$ can be computed by making a perfect square:

$$ax^2 + bx + c = a\left(x + \frac{b}{2a}\right)^2 - \frac{b^2}{4a} + c.$$

Then one should replace dx with the equal differential $d\bigl(x + \frac{b}{2a}\bigr)$ and use one of the four formulas in the second and third rows in the table of integrals given at the beginning of the current subsection.

Example 3. $\displaystyle\int \frac{dx}{\sqrt{2x-x^2}} = \int \frac{dx}{\sqrt{1-(x-1)^2}} = \int \frac{d(x-1)}{\sqrt{1-(x-1)^2}} = \arcsin(x-1) + C.$

4°. The integration of a polynomial multiplied by an exponential function can be accomplished by using the formula of integration by parts (or repeated integration by parts) given above.

Example 4. Compute the integral $\int (3x+1)\,e^{2x}\,dx$.

Taking $f(x)=3x+1$ and $g'(x)=e^{2x}$, one finds that $f'(x)=3$ and $g(x)=\frac{1}{2}e^{2x}$. On substituting these expressions into the formula of integration by parts, one obtains

$$\int (3x+1)\,e^{2x}\,dx=\frac{1}{2}(3x+1)\,e^{2x}-\frac{3}{2}\int e^{2x}\,dx=\frac{1}{2}(3x+1)\,e^{2x}-\frac{3}{4}e^{2x}+C=\Bigl(\frac{3}{2}x-\frac{1}{4}\Bigr)\,e^{2x}+C.$$

Remark 1. More complex examples of the application of integration by parts or repeated integration by parts can be found in Subsection M7.1.6.

Remark 2. Examples of using a change of variable (see Property 5 above) for the computation of integrals can be found in Subsections M7.1.4 and M7.1.5.

M7.1.3. Integration of Rational Functions

► **Partial fraction decomposition of a rational function.** A *rational function* (also known as a *rational polynomial function*) is a quotient of polynomials:

$$R(x)=\frac{P_n(x)}{Q_m(x)}, \tag{M7.1.3.1}$$

where

$$P_n(x)=a_nx^n+\cdots+a_1x+a_0,$$
$$Q_m(x)=b_mx^m+\cdots+b_1x+b_0.$$

The fraction (M7.1.3.1) is called *proper* if $m>n$ and *improper* if $m\le n$.

Every proper fraction (M7.1.3.1) can be decomposed into a sum of partial fractions. To this end, one should factorize the denominator $Q_m(x)$ into irreducible multipliers of the form

$$(x-\alpha_i)^{p_i}, \qquad i=1,2,\dots,k; \tag{M7.1.3.2a}$$
$$(x^2+\beta_jx+\gamma_j)^{q_j}, \qquad j=1,2,\dots,s, \tag{M7.1.3.2b}$$

where the p_i and q_j are positive integers satisfying the condition $p_1+\cdots+p_k+2(q_1+\cdots+q_s)=m$; $\beta_j^2-4\gamma_j<0$. The rational function (M7.1.3.1) can be represented as a sum of irreducibles and to each irreducible of the form (M7.1.3.2) there correspond as many terms as the power p_i or q_i:

$$\frac{A_{i,1}}{x-\alpha_i}+\frac{A_{i,2}}{(x-\alpha_i)^2}+\cdots+\frac{A_{i,p_i}}{(x-\alpha_i)^{p_i}}; \tag{M7.1.3.3a}$$
$$\frac{B_{j,1}x+D_{j,1}}{x^2+\beta_jx+\gamma_j}+\frac{B_{j,2}x+D_{j,2}}{(x^2+\beta_jx+\gamma_j)^2}+\cdots+\frac{B_{j,q_j}x+D_{j,q_j}}{(x^2+\beta_jx+\gamma_j)^{q_j}}. \tag{M7.1.3.3b}$$

The constants $A_{i,l}$, $B_{j,r}$, $D_{j,r}$ are found by the *method of undetermined coefficients*. To that end, one should equate the original rational fraction (M7.1.3.1) with the sum of the above partial fractions (M7.1.3.3) and reduce both sides of the resulting equation to a common denominator. Then, one collects the coefficients of like powers of x and equates them with zero, thus arriving at a system of linear algebraic equations for the $A_{i,l}$, $B_{j,r}$, and $D_{j,r}$.

Example 1. This is an illustration of how a proper fraction can be decomposed into partial fractions:

$$\frac{b_5x^5+b_4x^4+b_3x^3+b_2x^2+b_1x+b_0}{(x+a)(x+c)^3(x^2+k^2)}=\frac{A_{1,1}}{x+a}+\frac{A_{2,1}}{x+c}+\frac{A_{2,2}}{(x+c)^2}+\frac{A_{2,3}}{(x+c)^3}+\frac{Bx+D}{x^2+k^2}.$$

► Integration of a proper fraction.

1°. To integrate a proper fraction, one should first rewrite the integrand (M7.1.3.1) in the form of a sum of partial fractions. Below are the integrals of most common partial fractions (M7.1.3.3a) and (M7.1.3.3b) (with $q_j=1$):

$$\begin{aligned}&\int\frac{A}{x-\alpha}\,dx=A\ln|x-\alpha|,\qquad \int\frac{A}{(x-\alpha)^p}\,dx=-\frac{A}{(p-1)(x-\alpha)^{p-1}},\\&\int\frac{Bx+D}{x^2+\beta x+\gamma}\,dx=\frac{B}{2}\ln(x^2+\beta x+\gamma)+\frac{2D-B\beta}{\sqrt{4\gamma-\beta^2}}\arctan\frac{2x+\beta}{\sqrt{4\gamma-\beta^2}}.\end{aligned}\tag{M7.1.3.4}$$

The constant of integration C has been omitted here. More complex integrals of partial fractions (M7.1.3.3b) with $q_j>1$ can be computed using the formula

$$\int\frac{Bx+D}{(x^2+\beta x+\gamma)^q}\,dx=\frac{P(x)}{(x^2+\beta x+\gamma)^{q-1}}+\lambda\int\frac{dx}{x^2+\beta x+\gamma},\tag{M7.1.3.5}$$

where $P(x)$ is a polynomial of degree $2q-3$. The coefficients of $P(x)$ and the constant λ can be found by the method of undetermined coefficients by differentiating formula (M7.1.3.5).

Remark. The following recurrence relation may be used in order to compute the integrals on the left-hand side in (M7.1.3.5):

$$\int\frac{Bx+D}{(x^2+\beta x+\gamma)^q}\,dx=\frac{(2D-B\beta)x+D\beta-2B\gamma}{(q-1)(4\gamma-\beta^2)(x^2+\beta x+\gamma)^{q-1}}+\frac{(2q-3)(2D-B\beta)}{(q-1)(4\gamma-\beta^2)}\int\frac{dx}{(x^2+\beta x+\gamma)^{q-1}}.$$

Example 2. Compute the integral $\displaystyle\int\frac{3x^2-x-2}{x^3+8}\,dx$.

Let us factor the denominator of the integrand, $x^3+8=(x+2)(x^2-2x+4)$, and perform the partial fraction decomposition:

$$\frac{3x^2-x-2}{(x+2)(x^2-2x+4)}=\frac{A}{x+2}+\frac{Bx+D}{x^2-2x+4}.$$

Multiplying both sides by the common denominator and collecting the coefficients of like powers of x, we obtain

$$(A+B-3)x^2+(-2A+2B+D+1)x+4A+2D+2=0.$$

Now equating the coefficients of the different powers of x with zero, we arrive at a system of algebraic equations for A, B, and D:

$$A+B-3=0,\quad -2A+2B+D+1=0,\quad 4A+2D+2=0.$$

Its solution is: $A=1$, $B=2$, $D=-3$. Hence, we have

$$\begin{aligned}\int\frac{3x^2-x-2}{x^3+8}\,dx&=\int\frac{1}{x+2}\,dx+\int\frac{2x-3}{x^2-2x+4}\,dx\\&=\ln|x+2|+\ln\bigl(x^2-2x+4\bigr)-\frac{1}{\sqrt3}\arctan\frac{x-1}{\sqrt3}+C.\end{aligned}$$

Here, the last integral of (M7.1.3.4) has been used.

2°. The integrals of proper rational functions defined as the ratio of a polynomial to a power function $(x-\alpha)^m$ are given by the formulas

$$\int \frac{P_n(x)}{(x-\alpha)^m}\,dx = -\sum_{k=0}^{n} \frac{P_n^{(k)}(\alpha)}{k!\,(m-k-1)(x-\alpha)^{m-k-1}} + C, \qquad m > n+1;$$

$$\int \frac{P_n(x)}{(x-\alpha)^{n+1}}\,dx = -\sum_{k=0}^{n-1} \frac{P_n^{(k)}(\alpha)}{k!\,(n-k)(x-\alpha)^{n-k}} + \frac{P_n^{(n)}(\alpha)}{n!}\ln|x-\alpha| + C,$$

where $P_n(x)$ is a polynomial of degree n and $P_n^{(k)}(\alpha)$ is its kth derivative at $x=\alpha$.

3°. Suppose the roots in the factorization of the denominator of the fraction (M7.1.3.1) are all real and distinct:

$$Q_m(x) = b_m x^m + \cdots + b_1 x + b_0 = b_m(x-\alpha_1)(x-\alpha_2)\ldots(x-\alpha_m), \qquad \alpha_i \neq \alpha_j.$$

Then the following formula holds:

$$\int \frac{P_n(x)}{Q_m(x)}\,dx = \sum_{k=1}^{m} \frac{P_n(\alpha_k)}{Q'_m(\alpha_k)}\ln|x-\alpha_k| + C,$$

where $m > n$ and the prime denotes a derivative.

► **Integration of improper fractions.**

1°. In order to integrate an improper fraction, one should first isolate a proper fraction by division with remainder. As a result, the improper fraction is represented as the sum of a polynomial and a proper fraction,

$$\frac{a_n x^n + \cdots + a_1 x + a_0}{b_m x^m + \cdots + b_1 x + b_0} = c_m x^{n-m} + \cdots + c_1 x + c_0 + \frac{s_{m-1}x^{m-1} + \cdots + s_1 x + s_0}{b_m x^m + \cdots + b_1 x + b_0} \qquad (n \geq m),$$

which are then integrated separately.

Example 3. Evaluate the integral $I = \int \frac{x^2}{x-1}\,dx$.

Let us rewrite the integrand (improper fraction) as the sum of a polynomial and a proper fraction: $\frac{x^2}{x-1} = x + 1 + \frac{1}{x-1}$. Hence, $I = \int \left(x + 1 + \frac{1}{x-1}\right)dx = \frac{1}{2}x^2 + x + \ln|x-1| + C$.

2°. The integrals of improper rational functions defined as the ratio of a polynomial to a simple power function $(x-\alpha)^m$ are evaluated by the formula

$$\int \frac{P_n(x)}{(x-\alpha)^m}\,dx = \sum_{k=m}^{n} \frac{P_n^{(k)}(\alpha)}{k!\,(k-m+1)}(x-\alpha)^{k-m+1} + \frac{P_n^{(m-1)}(\alpha)}{(m-1)!}\ln|x-\alpha|$$
$$-\sum_{k=0}^{m-2} \frac{P_n^{(k)}(\alpha)}{k!\,(m-k-1)(x-\alpha)^{m-k-1}} + C,$$

where $n \geq m$.

Remark 1. The indefinite integrals of rational functions are always expressed in terms of elementary functions.

Remark 2. Some of the integrals reducible to integrals of rational functions are considered in Subsections M7.1.5 and M7.1.6.

M7.1.4. Integration of Irrational Functions

The integration of some irrational functions can be reduced to that of rational functions using a suitable change of variables. In what follows, the functions $R(x,y)$ and $R(x_1,\dots,x_k)$ are assumed to be rational functions in each of the arguments.

► **Integration of expressions involving radicals of linear-fractional functions.**

1°. The integrals with roots of linear functions

$$\int R\bigl(x,\ \sqrt[n]{ax+b}\bigr)\,dx$$

are reduced to integrals of rational functions by the change of variable $z=\sqrt[n]{ax+b}$.

Example 1. Evaluate the integral $I=\int x\sqrt{1-x}\,dx$.

With the change of variable $\sqrt{1-x}=z$, we have $x=1-z^2$ and $dx=-2z\,dz$. Substituting these expressions into the integral yields

$$I=-2\int(1-z^2)z^2\,dz=-\frac{2}{3}z^3+\frac{2}{5}z^5+C=-\frac{2}{3}\sqrt{(1-x)^3}+\frac{2}{5}\sqrt{(1-x)^5}+C.$$

2°. The integrals with roots of linear-fractional functions

$$\int R\left(x,\ \sqrt[n]{\frac{ax+b}{cx+d}}\right)dx$$

are reduced to integrals of rational functions by the substitution $z=\sqrt[n]{\dfrac{ax+b}{cx+d}}$.

3°. Integrals containing the product of a polynomial by a simple power function of the form $(x-a)^\beta$ are evaluated by the formula

$$\int P_n(x)(x-a)^\beta\,dx=\sum_{k=0}^{n}\frac{P_n^{(k)}(a)}{k!\,(k+\beta+1)}(x-a)^{k+\beta+1},$$

where $P_n(x)$ is a polynomial of degree n, $P_n^{(k)}(a)$ is its kth derivative at $x=a$, and β is any positive or negative proper fraction (to be more precise, $\beta\neq-1,-2,\dots,-n-1$).

► **Euler substitutions. Trigonometric substitutions.** We will be considering integrals involving the radical of a quadratic trinomial:

$$\int R\bigl(x,\sqrt{ax^2+bx+c}\bigr)\,dx,$$

where $b^2\neq 4ac$. Such integrals are expressible in terms of elementary functions.

1°. *Euler substitutions*. The given integral is reduced to the integral of a rational fraction by one of the following three Euler substitutions:

1) $\sqrt{ax^2+bx+c}=t\mp x\sqrt{a}$ if $a>0$;

2) $\sqrt{ax^2+bx+c}=xt\pm\sqrt{c}$ if $c>0$;

3) $\sqrt{ax^2+bx+c}=t(x-x_1)$ if $4ac-b^2<0$,

where x_1 is a root of the quadratic equation $ax^2+bx+c=0$. In all three cases, the variable x and the radical $\sqrt{ax^2+bx+c}$ are expressible in terms of the new variable t as (the formulas correspond to the upper signs in the substitutions):

$$\begin{aligned}
&1)\;\; x=\frac{t^2-c}{2\sqrt{a}\,t+b}, && \sqrt{ax^2+bx+c}=\frac{\sqrt{a}\,t^2+bt+c\sqrt{a}}{2\sqrt{a}\,t+b}, && dx=2\frac{\sqrt{a}\,t^2+bt+c\sqrt{a}}{(2\sqrt{a}\,t+b)^2}\,dt;\\
&2)\;\; x=\frac{2\sqrt{c}\,t-b}{a-t^2}, && \sqrt{ax^2+bx+c}=\frac{\sqrt{c}\,t^2-bt+c\sqrt{a}}{a-t^2}, && dx=2\frac{\sqrt{c}\,t^2-bt+c\sqrt{a}}{(a-t^2)^2}\,dt;\\
&3)\;\; x=\frac{(t^2+a)x_1+b}{t^2-a}, && \sqrt{ax^2+bx+c}=\frac{(2ax_1+b)t}{t^2-a}, && dx=-2\frac{(2ax_1+b)t}{(t^2-a)^2}\,dt.
\end{aligned}$$

2°. *Trigonometric substitutions*. The function $\sqrt{ax^2+bx+c}$ can be reduced, by making a perfect square in the radicand, to one of the three forms:

$$\begin{aligned}
&1)\;\; \sqrt{a}\sqrt{(x-p)^2+q^2} && \text{if}\quad a>0;\\
&2)\;\; \sqrt{a}\sqrt{(x-p)^2-q^2} && \text{if}\quad a>0;\\
&3)\;\; \sqrt{-a}\sqrt{q^2-(x-p)^2} && \text{if}\quad a<0,
\end{aligned}$$

where $p=-\frac{1}{2}b/a$. Different trigonometric substitutions are further used in each case to evaluate the integral:

$$\begin{aligned}
&1)\;\; x-p=q\tan t, && \sqrt{(x-p)^2+q^2}=\frac{q}{\cos t}, && dx=\frac{q\,dt}{\cos^2 t};\\
&2)\;\; x-p=\frac{q}{\cos t}, && \sqrt{(x-p)^2-q^2}=q\tan t, && dx=\frac{q\sin t\,dt}{\cos^2 t};\\
&3)\;\; x-p=q\sin t, && \sqrt{q^2-(x-p)^2}=q\cos t, && dx=q\cos t\,dt.
\end{aligned}$$

Example 2. Evaluate the integral $\int\sqrt{6+4x-2x^2}\,dx$.

This integral corresponds to case 3 with $a=-2$, $p=1$, and $q=2$. The integrand can be rewritten in the form:

$$\sqrt{6+4x-2x^2}=\sqrt{2}\sqrt{3+2x-x^2}=\sqrt{2}\sqrt{4-(x-1)^2}.$$

Using the trigonometric substitution $x-1=2\sin t$ and the formulas $\sqrt{3+2x-x^2}=2\cos t$ and $dx=2\cos t\,dt$, we obtain

$$\begin{aligned}
\int\sqrt{6+4x-2x^2}\,dx&=4\sqrt{2}\int\cos^2 t\,dt=2\sqrt{2}\int(1+\cos 2t)\,dt\\
&=2\sqrt{2}t+\sqrt{2}\sin 2t+C=2\sqrt{2}\arcsin\frac{x-1}{2}+\sqrt{2}\sin\Bigl(2\arcsin\frac{x-1}{2}\Bigr)+C\\
&=2\sqrt{2}\arcsin\frac{x-1}{2}+\frac{\sqrt{2}}{2}(x-1)\sqrt{4-(x-1)^2}+C.
\end{aligned}$$

► **Integral of a differential binomial.** The *integral of a differential binomial*,

$$\int x^m(a+bx^n)^p\,dx,$$

where a and b are constants, and n, m, p are rational numbers, is expressible in terms of elementary functions in the following three cases only:

1) If p is an integer. For $p \geq 0$, removing the brackets gives the sum of power functions. For $p < 0$, the substitution $x = t^r$, where r is the common denominator of the fractions m and n, leads to the integral of a rational function.

2) If $\frac{m+1}{n}$ is an integer. One uses the substitution $a+bx^n = t^k$, where k is the denominator of the fraction p.

3) If $\frac{m+1}{n} + p$ is an integer. One uses the substitution $ax^{-n} + b = t^k$, where k is the denominator of the fraction p.

Remark. In cases 2 and 3, the substitution $z = x^n$ leads to integrals of the form 3° above.

M7.1.5. Integration of Exponential and Trigonometric Functions

► Integration of exponential and hyperbolic functions.

1. Integrals of the form $\int R(e^{px}, e^{qx})\,dx$, where $R(x, y)$ is a rational function of its arguments and p, q are rational numbers, may be evaluated using the substitution $z^m = e^x$, where m is the common denominator of the fractions p and q. In the special case of integer p and q, we have $m = 1$, and the substitution becomes $z = e^x$.

Example 1. Evaluate the integral $\int \frac{e^{3x}\,dx}{e^x + 2}$.

This integral corresponds to integer p and q: $p = 1$ and $q = 3$. So we use the substitution $z = e^x$. Then $x = \ln z$ and $dx = \frac{dz}{z}$. Therefore,

$$\int \frac{e^{3x}\,dx}{e^x + 2} = \int \frac{z^2\,dz}{z + 2} = \int \Bigl(z - 2 + \frac{4}{z + 2}\Bigr) dz = \frac{1}{2}z^2 - 2z + 4\ln|z + 2| + C = \frac{1}{2}e^{2x} - 2e^x + 4\ln(e^x + 2) + C.$$

2. Integrals of the form $\int R(\sinh ax, \cosh ax)\,dx$ are evaluated by converting the hyperbolic functions to exponentials, using the formulas $\sinh ax = \frac{1}{2}(e^{ax} - e^{-ax})$ and $\cosh ax = \frac{1}{2}(e^{ax} + e^{-ax})$, and performing the substitution $z = e^{ax}$. Then

$$\int R(\sinh ax, \cosh ax)\,dx = \frac{1}{a}\int R\biggl(\frac{z^2 - 1}{2z}, \frac{z^2 + 1}{2z}\biggr)\frac{dz}{z}.$$

Alternatively, the substitution $t = \tanh\Bigl(\frac{ax}{2}\Bigr)$ can also be used to evaluate integrals of the above form. Then

$$\int R(\sinh ax, \cosh ax)\,dx = \frac{2}{a}\int R\biggl(\frac{2t}{1 - t^2}, \frac{1 + t^2}{1 - t^2}\biggr)\frac{dt}{1 - t^2}.$$

► Integration of trigonometric functions.

1. Integrals of the form $\int R(\sin ax, \cos ax)\,dx$ can be converted to integrals of rational functions using the fundamental trigonometric substitution $t = \tan\Bigl(\frac{ax}{2}\Bigr)$:

$$\int R(\sin ax, \cos ax)\,dx = \frac{2}{a}\int R\biggl(\frac{2t}{1 + t^2}, \frac{1 - t^2}{1 + t^2}\biggr)\frac{dt}{1 + t^2}.$$

Example 2. Evaluate the integral $\int \frac{dx}{2+\sin x}$.

Using the fundamental trigonometric substitution $t = \tan\frac{x}{2}$, we have

$$\int \frac{dx}{2+\sin x} = 2\int \frac{dt}{\left(2+\frac{2t}{1+t^2}\right)(1+t^2)} = \int \frac{dt}{t^2+t+1} = 2\int \frac{d(2t+1)}{(2t+1)^2+3}$$
$$= \frac{2}{\sqrt{3}}\arctan\frac{2t+1}{\sqrt{3}} + C = \frac{2}{\sqrt{3}}\arctan\left(\frac{2}{\sqrt{3}}\tan\frac{x}{2} + \frac{1}{\sqrt{3}}\right) + C.$$

2. Integrals of the form $\int R(\sin^2 ax, \cos^2 ax, \tan ax)\,dx$ are converted to integrals of rational functions with the change of variable $z = \tan ax$:

$$\int R(\sin^2 ax, \cos^2 ax, \tan ax)\,dx = \frac{1}{a}\int R\left(\frac{z^2}{1+z^2}, \frac{1}{1+z^2}, z\right)\frac{dz}{1+z^2}.$$

3. Integrals of the form

$$\int \sin ax \cos bx\,dx, \qquad \int \cos ax \cos bx\,dx, \qquad \int \sin ax \sin bx\,dx$$

are evaluated using the formulas

$$\begin{aligned}\sin\alpha\cos\beta &= \tfrac{1}{2}[\sin(\alpha+\beta)+\sin(\alpha-\beta)],\\ \cos\alpha\cos\beta &= \tfrac{1}{2}[\cos(\alpha+\beta)+\cos(\alpha-\beta)],\\ \sin\alpha\sin\beta &= \tfrac{1}{2}[\cos(\alpha-\beta)-\cos(\alpha+\beta)].\end{aligned}$$

4. Integrals of the form $\int \sin^m x\cos^n x\,dx$, where m and n are integers, are evaluated as follows:

(a) if m is odd, one uses the change of variable $\cos x = z$, with $\sin x\,dx = -dz$;
(b) if n is odd, one uses the change of variable $\sin x = z$, with $\cos x\,dx = dz$;
(c) if m and n are both even nonnegative integers, one should use the degree reduction formulas

$$\sin^2 x = \tfrac{1}{2}(1-\cos 2x), \quad \cos^2 x = \tfrac{1}{2}(1+\cos 2x), \quad \sin x\cos x = \tfrac{1}{2}\sin 2x.$$

Example 3. Evaluate the integral $\int \sin^5 x\,dx$.

This integral corresponds to odd m: $m = 5$. With simple rearrangement and the change of variable $\cos x = z$, we have

$$\int \sin^5 x\,dx = \int (\sin^2 x)^2 \sin x\,dx = -\int (1-\cos^2 x)^2\,d\cos x = -\int (1-z^2)^2\,dz$$
$$= \tfrac{2}{3}z^3 - \tfrac{1}{5}z^5 - z + C = \tfrac{2}{3}\cos^3 x - \tfrac{1}{5}\cos^5 x - \cos x + C.$$

Remark. In general, the integrals $\int \sin^p x\cos^q x\,dx$ are reduced to the integral of a differential binomial by the substitution $y = \sin x$.

M7.1.6. Integration of Polynomials Multiplied by Elementary Functions

Throughout this section, $P_n(x)$ designates a polynomial of degree n.

► **Integration of the product of a polynomial by exponential functions.** General formulas:

$$\int P_n(x)e^{ax}\,dx = e^{ax}\left[\frac{P_n(x)}{a} - \frac{P_n'(x)}{a^2} + \cdots + (-1)^n\frac{P_n^{(n)}(x)}{a^{n+1}}\right] + C,$$

$$\int P_n(x)\cosh(ax)\,dx = \sinh(ax)\left[\frac{P_n(x)}{a} + \frac{P_n''(x)}{a^3} + \cdots\right] - \cosh(ax)\left[\frac{P_n'(x)}{a^2} + \frac{P_n'''(x)}{a^4} + \cdots\right] + C,$$

$$\int P_n(x)\sinh(ax)\,dx = \cosh(ax)\left[\frac{P_n(x)}{a} + \frac{P_n''(x)}{a^3} + \cdots\right] - \sinh(ax)\left[\frac{P_n'(x)}{a^2} + \frac{P_n'''(x)}{a^4} + \cdots\right] + C.$$

These formulas are obtained by repeated integration by parts; see Property 4 from Subsection M7.1.2 with $f(x) = P_n(x)$ for $g^{(n+1)}(x) = e^{ax}$, $g^{(n+1)}(x) = \cosh(ax)$, and $g^{(n+1)}(x) = \sinh(ax)$, respectively.

In the special case $P_n(x) = x^n$, the first formula gives

$$\int x^n e^{ax}\,dx = e^{ax}\sum_{k=0}^{n}\frac{(-1)^{n-k}}{a^{n+1-k}}\frac{n!}{k!}x^k + C. \qquad \text{(M7.1.6.1)}$$

► **Integration of the product of a polynomial by a trigonometric function.**

1°. General formulas:

$$\int P_n(x)\cos(ax)\,dx = \sin(ax)\left[\frac{P_n(x)}{a} - \frac{P_n''(x)}{a^3} + \cdots\right] + \cos(ax)\left[\frac{P_n'(x)}{a^2} - \frac{P_n'''(x)}{a^4} + \cdots\right] + C,$$

$$\int P_n(x)\sin(ax)\,dx = \sin(ax)\left[\frac{P_n'(x)}{a^2} - \frac{P_n'''(x)}{a^4} + \cdots\right] - \cos(ax)\left[\frac{P_n(x)}{a} - \frac{P_n''(x)}{a^3} + \cdots\right] + C.$$

These formulas are obtained by repeated integration by parts; see Property 4 from Subsection M7.1.2 with $f(x) = P_n(x)$ for $g^{(n+1)}(x) = \cos(ax)$ and $g^{(n+1)}(x) = \sin(ax)$, respectively.

2°. To evaluate integrals of the form

$$\int P_n(x)\cos^m(ax)\,dx, \qquad \int P_n(x)\sin^m(ax)\,dx,$$

with $m = 2, 3, \ldots$, one should first use the trigonometric formulas

$$\cos^{2k}(ax) = \frac{1}{2^{2k-1}}\sum_{i=0}^{k-1}C_{2k}^{i}\cos[2(k-i)ax] + \frac{1}{2^{2k}}C_{2k}^{k} \qquad (m = 2k),$$

$$\cos^{2k+1}(ax) = \frac{1}{2^{2k}}\sum_{i=0}^{k}C_{2k+1}^{i}\cos[(2k-2i+1)ax] \qquad (m = 2k+1),$$

$$\sin^{2k}(ax) = \frac{1}{2^{2k-1}}\sum_{i=0}^{k-1}(-1)^{k-i}C_{2k}^{i}\cos[2(k-i)ax] + \frac{1}{2^{2k}}C_{2k}^{k} \qquad (m = 2k),$$

$$\sin^{2k+1}(ax) = \frac{1}{2^{2k}}\sum_{i=0}^{k}(-1)^{k-i}C_{2k+1}^{i}\sin[(2k-2i+1)ax] \qquad (m = 2k+1),$$

thus reducing the above integrals to those considered in Item 1°.

3°. Integrals of the form

$$\int P_n(x)\, e^{ax} \sin(bx)\, dx, \qquad \int P_n(x)\, e^{ax} \cos(bx)\, dx$$

can be evaluated by repeated integration by parts.

In particular,

$$\begin{aligned} \int x^n e^{ax} \sin(bx) &= e^{ax} \sum_{k=1}^{n+1} \frac{(-1)^{k+1} n!}{(n-k+1)!\,(a^2+b^2)^{k/2}} x^{n-k+1} \sin(bx+k\theta) + C, \\ \int x^n e^{ax} \cos(bx) &= e^{ax} \sum_{k=1}^{n+1} \frac{(-1)^{k+1} n!}{(n-k+1)!\,(a^2+b^2)^{k/2}} x^{n-k+1} \cos(bx+k\theta) + C, \end{aligned} \qquad (*)$$

where

$$\sin\theta = -\frac{b}{\sqrt{a^2+b^2}}, \qquad \cos\theta = \frac{a}{\sqrt{a^2+b^2}}.$$

▶ Integrals involving power and logarithmic functions.

1°. The formula of integration by parts with $g'(x) = P_n(x)$ is effective in the evaluation of integrals of the form

$$\int P_n(x) \ln(ax)\, dx = Q_{n+1}(x) \ln(ax) - a \int \frac{Q_{n+1}(x)}{x}\, dx,$$

where $Q_{n+1}(x) = \int P_n(x)\, dx$ is a polynomial of degree $n+1$. The integral on the right-hand side is easy to take, since the integrand is the sum of power functions.

Example. Evaluate the integral $\int \ln x\, dx$.

Setting $f(x) = \ln x$ and $g'(x) = 1$, we find $f'(x) = \frac{1}{x}$ and $g(x) = x$. Substituting these expressions into the formula of integration by parts, we obtain $\int \ln x\, dx = x \ln x - \int dx = x \ln x - x + C$.

2°. The easiest way to evaluate integrals of the more general form

$$I = \int \sum_{i=0}^{n} \ln^i(ax) \biggl(\sum_{j=0}^{m} b_{ij} x^{\beta_{ij}} \biggr)\, dx,$$

where the β_{ij} are arbitrary numbers, is to use the substitution $z = \ln(ax)$, so that

$$I = \int \sum_{i=0}^{n} z^i \biggl(\sum_{j=0}^{m} \frac{b_{ij}}{a^{\beta_{ij}+1}} e^{(\beta_{ij}+1)z} \biggr)\, dz.$$

By removing the brackets, one obtains a sum of integrals like $\int x^n e^{ax}\, dx$, which are easy to evaluate by formula (M7.1.6.1).

M7.2. Definite Integral

M7.2.1. Basic Definitions. Classes of Integrable Functions. Geometrical Meaning of the Definite Integral

► **Basic definitions.** Let $y = f(x)$ be a bounded function defined on a finite closed interval $[a, b]$. Let us partition this interval into n elementary subintervals defined by a set of points $\{x_0, x_1, \dots, x_n\}$ such that $a = x_0 < x_1 < \cdots < x_n = b$. Each subinterval $[x_{k-1}, x_k]$ will be characterized by its length $\Delta x_k = x_k - x_{k-1}$ and an arbitrarily chosen point $\xi_k \in [x_{k-1}, x_k]$. Let us make up an *integral sum* (a *Cauchy–Riemann sum*, also known as a *Riemann sum*)

$$s_n = \sum_{k=1}^{n} f(\xi_k)\Delta x_k \qquad (x_{k-1} \le \xi_k \le x_k).$$

If, as $\Delta x_k \to 0$ for all k and, accordingly, $n \to \infty$, there exists a finite limit of the integral sums s_n and it depends on neither the way the interval $[a, b]$ was partitioned, nor the selection of the points ξ_k, then this limit is denoted $\int_a^b f(x)\,dx$ and is called the *definite integral* (also the *Riemann integral*) of the function $y = f(x)$ over the interval $[a, b]$:

$$\int_a^b f(x)\,dx = \lim_{n\to\infty} s_n \qquad \Bigl(\max_{1\le k\le n} \Delta x_k \to 0\Bigr).$$

In this case, the function $f(x)$ is called *integrable* on the interval $[a, b]$.

► **Classes of integrable functions.**

1. If a function $f(x)$ is continuous on an interval $[a, b]$, then it is integrable on this interval.
2. If a bounded function $f(x)$ has finitely many jump discontinuities on $[a, b]$, then it is integrable on $[a, b]$.
3. A monotonic bounded function $f(x)$ on $[a, b]$ is always integrable on $[a, b]$.

► **Geometric meaning of the definite integral.** If $f(x) \ge 0$ on $[a, b]$, then the integral $\int_a^b f(x)\,dx$ is equal to the area of the domain $D = \{a \le x \le b,\ 0 \le y \le f(x)\}$ (the area of the curvilinear trapezoid shown in Fig. M7.1).

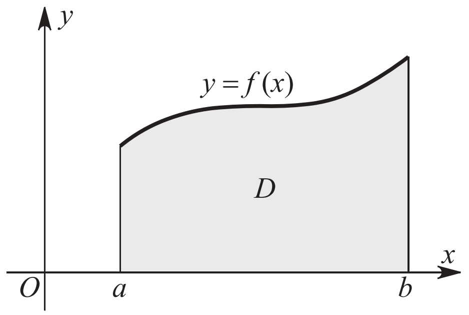

Figure M7.1. The integral of a nonnegative function $f(x)$ on an interval $[a, b]$ is equal to the area of the shaded region.

M7.2.2. Properties of Definite Integrals and Useful Formulas

► Qualitative properties of integrals.

1. If a function $f(x)$ is integrable on $[a,b]$, then the functions $cf(x)$, with $c = \text{const}$, and $|f(x)|$ are also integrable on $[a,b]$.

2. If two functions $f(x)$ and $g(x)$ are integrable on $[a,b]$, then their sum, difference, and product are also integrable on $[a,b]$.

3. If a function $f(x)$ is integrable on $[a,b]$ and its values lie within an interval $[c,d]$, where a function $g(y)$ is defined and continuous, then the composite function $g(f(x))$ is also integrable on $[a,b]$.

4. If a function $f(x)$ is integrable on $[a,b]$, then it is also integrable and on any subinterval $[\alpha,\beta] \subset [a,b]$. Conversely, if an interval $[a,b]$ is partitioned into a number of subintervals and $f(x)$ is integrable on each of the subintervals, then it is integrable on the whole interval $[a,b]$.

5. If the values of a function are changed at finitely many points, this will not affect the integrability of the function and will not change the value of the integral.

► Properties of integrals in terms of identities.

1. *The integral over a zero-length interval is zero*:

$$\int_a^a f(x)\,dx = 0.$$

2. *Antisymmetry under the swap of the integration limits*:

$$\int_a^b f(x)\,dx = -\int_b^a f(x)\,dx.$$

3. *Linearity*. If functions $f(x)$ and $g(x)$ are integrable on an interval $[a,b]$, then

$$\int_a^b \bigl[Af(x) \pm Bg(x)\bigr]\,dx = A\int_a^b f(x)\,dx \pm B\int_a^b g(x)\,dx$$

for any numbers A and B.

4. *Additivity*. If $c \in [a,b]$ and $f(x)$ is integrable on $[a,b]$, then

$$\int_a^b f(x)\,dx = \int_a^c f(x)\,dx + \int_c^b f(x)\,dx.$$

Remark. This property is also valid in the case where $c \notin [a,b]$.

5. *Differentiation with respect to a variable upper limit*. If $f(x)$ is continuous on $[a,b]$, then the function $\Phi(x) = \int_a^x f(t)\,dt$ is differentiable on $[a,b]$, and $\Phi'(x) = f(x)$. This fact can be written as

$$\frac{d}{dx}\left(\int_a^x f(t)\,dt\right) = f(x).$$

6. *Newton–Leibniz formula*:

$$\int_a^b f(x)\,dx = F(x)\Big|_a^b = F(b) - F(a),$$

where $F(x)$ is an antiderivative of $f(x)$ on $[a,b]$.

7. *Integration by parts*. If functions $f(x)$ and $g(x)$ have continuous derivatives on $[a,b]$, then

$$\int_a^b f(x)g'(x)\,dx = \bigl[f(x)g(x)\bigr]\Big|_a^b - \int_a^b f'(x)g(x)\,dx.$$

8. *Repeated integration by parts*:

$$\int_a^b f(x)g^{(n+1)}(x)\,dx = \Bigl[f(x)g^{(n)}(x) - f'(x)g^{(n-1)}(x) + \cdots + (-1)^n f^{(n)}(x)g(x)\Bigr]_a^b$$
$$+ (-1)^{n+1}\int_a^b f^{(n+1)}(x)g(x)\,dx, \qquad n = 0,\ 1,\ \ldots$$

9. *Change of variable (substitution) in a definite integral*. Let $f(x)$ be a continuous function on $[a,b]$ and let $x(t)$ be a continuously differentiable function on $[\alpha,\beta]$. Suppose also that the range of values of $x(t)$ coincides with $[a,b]$, with $x(\alpha) = a$ and $x(\beta) = b$. Then

$$\int_a^b f(x)\,dx = \int_\alpha^\beta f\bigl(x(t)\bigr)\,x'(t)\,dt.$$

Example. Evaluate the integral $\displaystyle\int_0^3 \frac{dx}{(x-8)\sqrt{x+1}}$.

Perform the substitution $x + 1 = t^2$, with $dx = 2t\,dt$. We have $t = 1$ at $x = 0$ and $t = 2$ at $x = 3$. Therefore,

$$\int_0^3 \frac{dx}{(x-8)\sqrt{x+1}} = \int_1^2 \frac{2t\,dt}{(t^2-9)t} = 2\int_1^2 \frac{dt}{t^2-9} = \frac{1}{3}\ln\left|\frac{t-3}{t+3}\right|\Bigg|_1^2 = \frac{1}{3}\ln\frac{2}{5}.$$

M7.2.3. Asymptotic Formulas for the Calculation of Integrals

Below are some general formulas, involving arbitrary functions and parameters, that may be helpful for obtaining asymptotics of integrals.

► **Asymptotic formulas for integrals with weak singularity as $\varepsilon \longrightarrow 0$.** We will consider integrals of the form

$$I(\varepsilon) = \int_0^a \frac{x^{\beta-1}f(x)}{(x+\varepsilon)^\alpha}\,dx,$$

where $0 < a < \infty$, $\beta > 0$, $f(0) \neq 0$, and $\varepsilon > 0$ is a small parameter.

The integral diverges as $\varepsilon \to 0$ for $\alpha \geq \beta$, that is, $\lim\limits_{\varepsilon\to 0} I(\varepsilon) = \infty$. In this case, the leading term of the asymptotic expansion of the integral $I(\varepsilon)$ is given by

$$\begin{aligned} I(\varepsilon) &= \frac{\Gamma(\beta)\Gamma(\alpha-\beta)}{\Gamma(\alpha)} f(0)\varepsilon^{\beta-\alpha} + O(\varepsilon^\sigma) && \text{if} \quad \alpha > \beta, \\ I(\varepsilon) &= -f(0)\ln\varepsilon + O(1) && \text{if} \quad \alpha = \beta, \end{aligned}$$

where $\Gamma(\beta)$ is the gamma function and $\sigma = \min[\beta - \alpha + 1,\ 0]$.

► **Asymptotic formulas for Laplace integrals of special form as $\lambda \longrightarrow +\infty$.** Consider a *Laplace integral of the special form*

$$I(\lambda) = \int_0^a x^{\beta-1}\exp\bigl(-\lambda x^\alpha\bigr)f(x)\,dx,$$

where $0 < a < \infty$, $\alpha > 0$, and $\beta > 0$.

The following formula, called *Watson's asymptotic formula*, holds as $\lambda \to +\infty$:

$$I(\lambda) = \frac{1}{\alpha}\sum_{k=0}^{n}\frac{f^{(k)}(0)}{k!}\Gamma\Bigl(\frac{k+\beta}{\alpha}\Bigr)\lambda^{-(k+\beta)/\alpha} + O\bigl(\lambda^{-(n+\beta+1)/\alpha}\bigr).$$

Remark. Watson's formula also holds for improper integrals with $a = \infty$ if the original integral converges absolutely for some $\lambda_0 > 0$.

► **Asymptotic formulas for Laplace integrals of general form as $\lambda \to +\infty$.** Consider a *Laplace integral of the general form*

$$I(\lambda) = \int_a^b f(x)\exp[\lambda g(x)]\,dx, \qquad \text{(M7.2.3.1)}$$

where $[a, b]$ is a finite interval and $f(x)$, $g(x)$ are continuous functions.

Leading term of the asymptotic expansion of the integral (M7.2.3.1) as $\lambda \to +\infty$. Suppose the function $g(x)$ attains a maximum on $[a, b]$ at only one point $x_0 \in [a, b]$ and is differentiable in a neighborhood of x_0, with $g'(x_0) = 0$, $g''(x_0) \neq 0$, and $f(x_0) \neq 0$. Then the leading term of the asymptotic expansion of the integral (M7.2.3.1), as $\lambda \to +\infty$, is given by

$$\begin{aligned} I(\lambda) &= f(x_0)\sqrt{-\frac{2\pi}{\lambda g''(x_0)}}\exp[\lambda g(x_0)] \quad &&\text{if } a < x_0 < b,\\ I(\lambda) &= \frac{1}{2}f(x_0)\sqrt{-\frac{2\pi}{\lambda g''(x_0)}}\exp[\lambda g(x_0)] \quad &&\text{if } x_0 = a \text{ or } x_0 = b. \end{aligned} \qquad \text{(M7.2.3.2)}$$

Note that the latter formula differs from the former by the factor $1/2$ only.

Under the same conditions, if $g(x)$ attains a maximum at either endpoint, $x_0 = a$ or $x_0 = b$, but $g'(x_0) \neq 0$, then the leading asymptotic term of the integral, as $\lambda \to +\infty$, is

$$I(\lambda) = \frac{f(x_0)}{|g'(x_0)|}\frac{1}{\lambda}\exp[\lambda g(x_0)], \quad \text{where } x_0 = a \text{ or } x_0 = b. \qquad \text{(M7.2.3.3)}$$

For more accurate asymptotic estimates for the Laplace integral (M7.2.3.1), see below.

► **Asymptotic formulas for a power Laplace integral.** Consider the *power Laplace integral*, which is obtained from the exponential Laplace integral (M7.2.3.1) by substituting $\ln g(x)$ for $g(x)$:

$$I(\lambda) = \int_a^b f(x)[g(x)]^\lambda\,dx, \qquad \text{(M7.2.3.6)}$$

where $[a, b]$ is a finite closed interval and $g(x) > 0$. It is assumed that the functions $f(x)$ and $g(x)$ appearing in the integral (M7.2.3.6) are continuous; $g(x)$ is assumed to attain a maximum at only one point $x_0 = [a, b]$ and to be differentiable in a neighborhood of $x = x_0$, with $g'(x_0) = 0$, $g''(x_0) \neq 0$, and $f(x_0) \neq 0$. Then the leading asymptotic term of the integral, as $\lambda \to +\infty$, is expressed as

$$\begin{aligned} I(\lambda) &= f(x_0)\sqrt{-\frac{2\pi}{\lambda g''(x_0)}}\,[g(x_0)]^{\lambda+1/2} \quad &&\text{if } a < x_0 < b,\\ I(\lambda) &= \frac{1}{2}f(x_0)\sqrt{-\frac{2\pi}{\lambda g''(x_0)}}\,[g(x_0)]^{\lambda+1/2} \quad &&\text{if } x_0 = a \text{ or } x_0 = b. \end{aligned}$$

Note that the latter formula differs from the former by the factor $1/2$ only.

Under the same conditions, if $g(x)$ attains a maximum at either endpoint, $x_0 = a$ or $x_0 = b$, but $g'(x_0) \neq 0$, then the leading asymptotic term of the integral, as $\lambda \to +\infty$, is

$$I(\lambda) = \frac{f(x_0)}{|g'(x_0)|}\frac{1}{\lambda}[g(x_0)]^{\lambda+1/2}, \qquad \text{where } x_0 = a \text{ or } x_0 = b.$$

M7.2.4. Mean Value Theorems. Properties of Integrals in Terms of Inequalities

► Mean value theorems.

THEOREM 1. *If $f(x)$ is a continuous function on $[a,b]$, there exists at least one point $c \in (a,b)$ such that*

$$\int_a^b f(x)\,dx = f(c)(b-a).$$

The number $f(c)$ is called the mean value of the function $f(x)$ on $[a,b]$.

THEOREM 2. *If $f(x)$ is a continuous function on $[a,b]$, and $g(x)$ is integrable and of constant sign ($g(x) \geq 0$ or $g(x) \leq 0$) on $[a,b]$, then there exists at least one point $c \in (a,b)$ such that*

$$\int_a^b f(x)g(x)\,dx = f(c)\int_a^b g(x)\,dx.$$

► Properties of integrals in terms of inequalities.

1. *Estimation theorem*. If $m \leq f(x) \leq M$ on $[a,b]$, then

$$m(b-a) \leq \int_a^b f(x)\,dx \leq M(b-a).$$

2. *Inequality integration theorem*. If $\varphi(x) \leq f(x) \leq g(x)$ on $[a,b]$, then

$$\int_a^b \varphi(x)\,dx \leq \int_a^b f(x)\,dx \leq \int_a^b g(x)\,dx.$$

In particular, if $f(x) \geq 0$ on $[a,b]$, then $\int_a^b f(x)\,dx \geq 0$.

Further on, it is assumed that the integrals on the right-hand sides of the inequalities of Items 3–6 exist.

3. *Absolute value theorem* (*integral analogue of the triangle inequality*):

$$\left|\int_a^b f(x)\,dx\right| \leq \int_a^b |f(x)|\,dx.$$

4. *Bunyakovsky's inequality* (*Cauchy–Schwarz–Bunyakovsky inequality*):

$$\left(\int_a^b f(x)g(x)\,dx\right)^2 \leq \int_a^b f^2(x)\,dx \int_a^b g^2(x)\,dx.$$

5. *Cauchy's inequality*:

$$\left(\int_a^b [f(x)+g(x)]^2\,dx\right)^{1/2} \leq \left(\int_a^b f^2(x)\,dx\right)^{1/2} + \left(\int_a^b g^2(x)\,dx\right)^{1/2}.$$

6. *Minkowski's inequality* (generalization of Cauchy's inequality):

$$\left(\int_a^b |f(x)+g(x)|^p\,dx\right)^{\frac{1}{p}} \leq \left(\int_a^b |f(x)|^p\,dx\right)^{\frac{1}{p}} + \left(\int_a^b |g(x)|^p\,dx\right)^{\frac{1}{p}}, \qquad p \geq 1.$$

M7.2.5. Geometric and Physical Applications of the Definite Integral

► **Geometric applications of the definite integral.**

1. The *area of a domain* D bounded by curves $y = f(x)$ and $y = g(x)$ and straight lines $x = a$ and $x = b$ in the xy-plane (see Fig. M7.2 *a*) is calculated by the formula

$$S = \int_a^b \bigl[f(x) - g(x)\bigr]\,dx.$$

If $g(x) \equiv 0$, this formula gives the area of a curvilinear trapezoid bounded by the x-axis, the curve $y = f(x)$, and the straight lines $x = a$ and $x = b$.

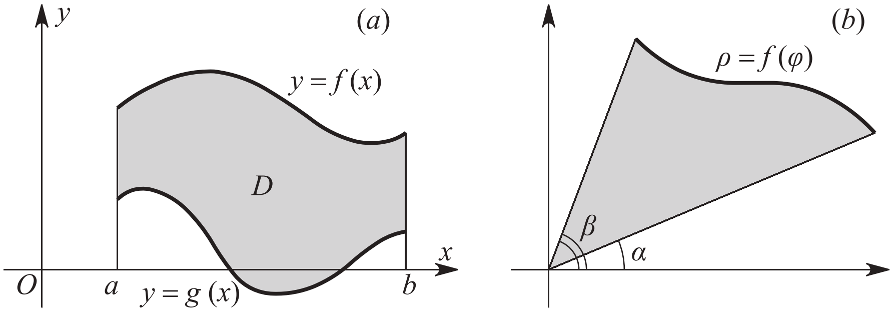

Figure M7.2. (*a*) A domain D bounded by two curves $y = f(x)$ and $y = g(x)$ on an interval $[a, b]$; (*b*) a curvilinear sector.

2. *Area of a domain* D. Let $x = x(t)$ and $y = y(t)$, with $t_1 \le t \le t_2$, be parametric equations of a piecewise-smooth simple closed curve bounding on its left (traced counterclockwise) a domain D with area S. Then

$$S = -\int_{t_1}^{t_2} y(t)x'(t)\,dt = \int_{t_1}^{t_2} x(t)y'(t)\,dt = \frac{1}{2}\int_{t_1}^{t_2} \bigl[x(t)y'(t) - y(t)x'(t)\bigr]\,dt.$$

3. *Area of a curvilinear sector*. Let a curve $\rho = f(\varphi)$, with $\varphi \in [\alpha, \beta]$, be defined in the polar coordinates ρ, φ. Then the area of the curvilinear sector $\{\alpha \le \varphi \le \beta;\ 0 \le \rho \le f(\varphi)\}$ (see Fig. M7.2 *b*) is calculated by the formula

$$S = \frac{1}{2}\int_\alpha^\beta [f(\varphi)]^2\,d\varphi.$$

4. *Area of a surface of revolution*. Let a surface of revolution be generated by rotating a curve $y = f(x) \ge 0$, $x \in [a, b]$, about the x-axis; see Fig. M7.3. The area of this surface is calculated as

$$S = 2\pi \int_a^b f(x)\sqrt{1 + [f'(x)]^2}\,dx.$$

5. *Volume of a body of revolution*. Let a body of revolution be obtained by rotating about the x-axis a curvilinear trapezoid bounded by a curve $y = f(x)$, the x-axis, and straight lines $x = a$ and $x = b$; see Fig. M7.3. Then the volume of this body is calculated as

$$V = \pi \int_a^b [f(x)]^2\,dx.$$

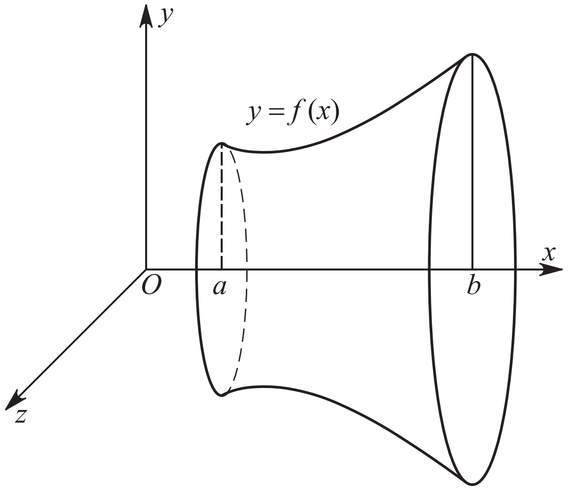

Figure M7.3. A surface of revolution generated by rotating a curve $y = f(x)$.

6. *Arc length of a plane curve defined in different ways.*

(*a*) If a curve is the graph of a continuously differentiable function $y = f(x)$, $x \in [a, b]$, then its length is determined as

$$L = \int_a^b \sqrt{1 + [f'(x)]^2}\, dx.$$

(*b*) If a plane curve is defined parametrically by equations $x = x(t)$ and $y = y(t)$, with $t \in [\alpha, \beta]$ and $x(t)$ and $y(t)$ being continuously differentiable functions, then its length is calculated by

$$L = \int_\alpha^\beta \sqrt{[x'(t)]^2 + [y'(t)]^2}\, dt.$$

(*c*) If a curve is defined in the polar coordinates ρ, φ by an equation $\rho = \rho(\varphi)$, with $\varphi \in [\alpha, \beta]$, then its length is found as

$$L = \int_\alpha^\beta \sqrt{\rho^2(\varphi) + [\rho'(\varphi)]^2}\, d\varphi.$$

7. The *arc length of a spatial curve* defined parametrically by equations $x = x(t)$, $y = y(t)$, and $z = z(t)$, with $t \in [\alpha, \beta]$ and $x(t)$, $y(t)$, and $z(t)$ being continuously differentiable functions, is calculated by

$$L = \int_\alpha^\beta \sqrt{[x'(t)]^2 + [y'(t)]^2 + [z'(t)]^2}\, dt.$$

► Physical applications of the integral.

1. *Work of a variable force*. Suppose a point mass moves along the x-axis from a point $x = a$ to a point $x = b$ under the action of a variable force $F(x)$ directed along the x-axis. The mechanical work of this force is equal to

$$A = \int_a^b F(x)\, dx.$$

2. *Mass of a rectilinear rod of variable density.* Suppose a rod with a constant cross-sectional area S occupies an interval $[0, l]$ on the x-axis and the density of the rod material is a function of x: $\rho = \rho(x)$. The mass of this rod is calculated as

$$m = S\int_0^l \rho(x)\,dx.$$

3. *Mass of a curvilinear rod of variable density.* Let the shape of a plane curvilinear rod with a constant cross-sectional area S be defined by an equation $y = f(x)$, with $a \le x \le b$, and let the density of the material be coordinate dependent: $\rho = \rho(x, y)$. The mass of this rod is calculated as

$$m = S\int_a^b \rho\bigl(x, f(x)\bigr)\sqrt{1 + [y'(x)]^2}\,dx.$$

If the shape of the rod is defined parametrically by $x = x(t)$ and $y = y(t)$, then its mass is found as

$$m = S\int_a^b \rho\bigl(x(t), y(t)\bigr)\sqrt{[x'(t)]^2 + [y'(t)]^2}\,dt.$$

4. The *coordinates of the center of mass of a plane homogeneous material curve* whose shape is defined by an equation $y = f(x)$, with $a \le x \le b$, are calculated by the formulas

$$x_{\rm c} = \frac{1}{L}\int_a^b x\sqrt{1 + [y'(x)]^2}\,dx, \qquad y_{\rm c} = \frac{1}{L}\int_a^b f(x)\sqrt{1 + [y'(x)]^2}\,dx,$$

where L is the length of the curve.

If the shape of a plane homogeneous material curve is defined parametrically by $x = x(t)$ and $y = y(t)$, then the coordinates of its center of mass are obtained as

$$x_{\rm c} = \frac{1}{L}\int_a^b x(t)\sqrt{[x'(t)]^2 + [y'(t)]^2}\,dt, \qquad y_{\rm c} = \frac{1}{L}\int_a^b y(t)\sqrt{[x'(t)]^2 + [y'(t)]^2}\,dt.$$

5. The *coordinates of the center of mass of a homogeneous curvilinear trapezoid* bounded by a curve $y = f(x)$, the x-axis, and the straight lines $x = a$ and $x = b$ (see Fig. M7.1) are given by

$$x_{\rm c} = \frac{1}{S}\int_a^b xf(x)\,dx, \quad y_{\rm c} = \frac{1}{2S}\int_a^b [f(x)]^2\,dx, \qquad S = \int_a^b f(x)\,dx,$$

where S is the area of the trapezoid.

M7.2.6. Improper Integrals with Infinite Integration Limits

An improper integral is an integral with an infinite limit (limits) of integration or an integral of an unbounded function.

► Integrals with infinite limits.

1°. Let $y = f(x)$ be a function defined and continuous on an infinite interval $a \le x < \infty$. If there exists a finite limit $\lim\limits_{b\to\infty}\int_a^b f(x)\,dx$, then it is called a (convergent) *improper integral* of $f(x)$ on the interval $[a, \infty)$ and is denoted

$\int_a^\infty f(x)\,dx$. Thus, by definition

$$\int_a^\infty f(x)\,dx = \lim_{b\to\infty} \int_a^b f(x)\,dx. \qquad \text{(M7.2.6.1)}$$

If the limit is infinite or does not exist, the improper integral is called *divergent*.

The *geometric meaning of an improper integral* is that the integral $\int_a^\infty f(x)\,dx$, with $f(x) \ge 0$, is equal to the area of the unbounded domain between the curve $y = f(x)$, its asymptote $y = 0$, and the straight line $x = a$ on the left.

2°. Suppose an antiderivative $F(x)$ of the integrand function $f(x)$ is known. Then the improper integral (M7.2.6.1) is

(i) *convergent* if there exists a finite limit $\lim_{x\to\infty} F(x) = F(\infty)$;

(ii) *divergent* if the limit is infinite or does not exist.

In case (i), we have

$$\int_a^\infty f(x)\,dx = F(x)\Big|_a^\infty = F(\infty) - F(a).$$

Example 1. Let us investigate the improper integral $I = \int_a^\infty \frac{dx}{x^\lambda}$, $a > 0$.

The integrand $f(x) = x^{-\lambda}$ has an antiderivative $F(x) = \frac{1}{1-\lambda} x^{1-\lambda}$ if $\lambda \ne 1$. Depending on the value of the parameter λ, we have

$$\lim_{x\to\infty} F(x) = \frac{1}{1-\lambda} \lim_{x\to\infty} x^{1-\lambda} = \begin{cases} 0 & \text{if } \lambda > 1, \\ \infty & \text{if } \lambda < 1. \end{cases}$$

Therefore, if $\lambda > 1$, the integral is convergent and is equal to $I = F(\infty) - F(a) = \frac{a^{1-\lambda}}{\lambda - 1}$, and if $\lambda < 1$, the integral is divergent. It is easy to show that the integral is also divergent if $\lambda = 1$.

3°. Improper integrals for other infinite intervals are defined in a similar way:

$$\int_{-\infty}^b f(x)\,dx = \lim_{a\to-\infty} \int_a^b f(x)\,dx,$$
$$\int_{-\infty}^\infty f(x)\,dx = \int_{-\infty}^c f(x)\,dx + \int_c^\infty f(x)\,dx,$$

where c is an arbitrary number. Note that if either improper integral on the right-hand side of the latter relation is convergent, then, by definition, the integral on the left-hand side is also convergent. If at least one of the integrals on the right-hand side is divergent, the integral on the left is called divergent.

4°. Properties 2–4 and 6–9 from Subsection M7.2.2, where a can be equal to $-\infty$ and b can be ∞, apply to improper integrals as well; it is assumed that all quantities on the right-hand sides exist (the integrals are convergent).

► **Sufficient conditions for convergence of improper integrals.** In many problems, it suffices to establish whether a given improper integral is convergent or not and, if yes, evaluate it. The theorems presented below can be useful in doing so.

THEOREM 1 (CAUCHY'S CONVERGENCE CRITERION). *For the integral (M7.2.6.1) to be convergent it is necessary and sufficient that for any* $\varepsilon > 0$ *there exist a number* R *such that the inequality*

$$\left|\int_{\alpha}^{\beta} f(x)\,dx\right| < \varepsilon$$

holds for any $\beta > \alpha > R$.

THEOREM 2. *If* $0 \le f(x) \le g(x)$ *for* $x \ge a$, *then the convergence of the integral* $\int_a^\infty g(x)\,dx$ *implies the convergence of the integral* $\int_a^\infty f(x)\,dx$*; moreover,* $\int_a^\infty f(x)\,dx \le \int_a^\infty g(x)\,dx$. *If the integral* $\int_a^\infty f(x)\,dx$ *is divergent, then the integral* $\int_a^\infty g(x)\,dx$ *is also divergent.*

THEOREM 3. *If the integral* $\int_a^\infty |f(x)|\,dx$ *is convergent, then the integral* $\int_a^\infty f(x)\,dx$ *is also convergent; in this case, the latter integral is called absolutely convergent.*

Example 2. The improper integral $\int_1^\infty \frac{\sin x}{x^2}\,dx$ is absolutely convergent, since $\left|\frac{\sin x}{x^2}\right| \le \frac{1}{x^2}$ and the integral $\int_1^\infty \frac{1}{x^2}\,dx$ is convergent (see Example 1).

THEOREM 4. *Let* $f(x)$ *and* $g(x)$ *be integrable functions on any finite interval* $a \le x \le b$ *and let there exist a limit, finite or infinite,*

$$\lim_{x\to\infty} \frac{f(x)}{g(x)} = K.$$

Then the following assertions hold:

1. If $0 < K < \infty$, *both integrals*

$$\int_a^\infty f(x)\,dx, \qquad \int_a^\infty g(x)\,dx \tag{M7.2.6.2}$$

are convergent or divergent simultaneously.

2. If $0 \le K < \infty$, *the convergence of the latter integral in (M7.2.6.2) implies the convergence of the former integral.*

3. If $0 < K \le \infty$, *the divergence of the latter integral in (M7.2.6.2) implies the divergence of the former integral.*

THEOREM 5 (COROLLARY OF THEOREM 4). *Given a function* $f(x)$, *let its asymptotics for sufficiently large* x *have the form*

$$f(x) = \frac{\varphi(x)}{x^\lambda} \qquad (\lambda > 0).$$

Then: (i) if $\lambda > 1$ *and* $\varphi(x) \le c < \infty$, *then the integral* $\int_a^\infty f(x)\,dx$ *is convergent; (ii) if* $\lambda \le 1$ *and* $\varphi(x) \ge c > 0$, *then the integral is divergent.*

THEOREM 6. *Let* $f(x)$ *be an absolutely integrable function on an interval* $[a, \infty)$ *and let* $g(x)$ *be a bounded function on* $[a, \infty)$. *Then the product* $f(x)g(x)$ *is an absolutely integrable function on* $[a, \infty)$.

THEOREM 7 (ANALOGUE OF ABEL'S TEST FOR CONVERGENCE OF INFINITE SERIES). *Let* $f(x)$ *be an integrable function on an interval* $[a, \infty)$ *such that the integral (M7.2.6.1) is* *convergent (maybe not absolutely) and let $g(x)$ be a monotonic and bounded function on $[a,\infty)$. Then the integral*

$$\int_a^\infty f(x)g(x)\,dx \qquad (M7.2.6.3)$$

is convergent.

THEOREM 8 (ANALOGUE OF DIRICHLET'S TEST FOR CONVERGENCE OF INFINITE SERIES). *Let (i) $f(x)$ be an integrable function on any finite interval $[a,A]$ and*

$$\left|\int_a^A f(x)\,dx\right| \le K < \infty \qquad (a \le A < \infty);$$

(ii) $g(x)$ be a function tending to zero monotonically as $x \to \infty$: $\lim\limits_{x\to\infty} g(x) = 0$. Then the integral (M7.2.6.3) is convergent.

Example 3. Let us show that the improper integral $\displaystyle\int_a^\infty \frac{\sin x}{x^\lambda}\,dx$ is convergent for $a > 0$ and $\lambda > 0$.

Set $f(x) = \sin x$ and $g(x) = x^{-\lambda}$ and verify conditions (i) and (ii) of Theorem 8. We have

(i) $\displaystyle\left|\int_a^A \sin x\,dx\right| = |\cos a - \cos A| \le 2;$

(ii) since $\lambda > 0$, the function $x^{-\lambda}$ is monotonically decreasing and tends to zero as $x \to \infty$.

So both conditions of Theorem 8 are met, and therefore the given improper integral is convergent.

M7.2.7. Improper Integrals of Unbounded Functions

► Basic definitions.

1°. Let a function $f(x)$ be defined and continuous for $a \le x < b$, but $\lim\limits_{x\to b-0} f(x) = \infty$. If there exists a finite limit $\lim\limits_{\lambda\to b-0}\int_a^\lambda f(x)\,dx$, it is called the (convergent) *improper integral of the unbounded function* $f(x)$ over the interval $[a,b]$. Thus, by definition

$$\int_a^b f(x)\,dx = \lim_{\lambda\to b-0}\int_a^\lambda f(x)\,dx. \qquad \text{(M7.2.7.1)}$$

If no finite limit exists, the integral is called *divergent*.

If $\lim\limits_{x\to a+0} f(x) = \infty$, then, by definition, it is assumed that

$$\int_a^b f(x)\,dx = \lim_{\gamma\to a+0}\int_\gamma^b f(x)\,dx.$$

Finally, if $f(x)$ is unbounded near a point $c \in (a,b)$ and both integrals $\int_a^c f(x)\,dx$ and $\int_c^b f(x)\,dx$ are convergent, then, by definition,

$$\int_a^b f(x)\,dx = \int_a^c f(x)\,dx + \int_c^b f(x)\,dx.$$

If at least one of the integrals on the right-hand side is divergent, the integral on the left-hand side is called divergent.

2°. The geometric meaning of an improper integral of an unbounded function and also sufficient conditions for convergence of such integrals are similar to those for improper integrals with infinite limit(s).

► **Convergence tests for improper integrals of unbounded functions.** Presented below are theorems for the case where the only singular point of the integrand function is the right endpoint of the interval $[a, b]$.

THEOREM 1 (CAUCHY'S CONVERGENCE CRITERION). *For the integral (M7.2.7.1) to be convergent it is necessary and sufficient that for any* $\varepsilon > 0$ *there exist a number* $\delta > 0$ *such that for any* δ_1 *and* δ_2 *satisfying* $0 < \delta_1 < \delta$ *and* $0 < \delta_2 < \delta$ *the following inequality holds:*

$$\left|\int_{b-\delta_1}^{b-\delta_2} f(x)\,dx\right| < \varepsilon.$$

THEOREM 2. *If* $0 \le f(x) \le g(x)$ *for* $a \le x < b$, *then the convergence of the integral* $\int_a^b g(x)\,dx$ *implies the convergence of the integral* $\int_a^b f(x)\,dx$, *with* $\int_a^b f(x)\,dx \le \int_a^b g(x)\,dx$. *If the integral* $\int_a^b f(x)\,dx$ *is divergent, then the integral* $\int_a^b g(x)\,dx$ *is also divergent.*

Example. For any continuous function $\varphi(x)$ such that $\varphi(1) = 0$, the improper integral $\int_0^1 \frac{dx}{\varphi^2(x) + \sqrt{1-x}}$ is convergent and does not exceed 2, since $\frac{1}{\varphi^2(x) + \sqrt{1-x}} < \frac{1}{\sqrt{1-x}}$, while the integral $\int_0^1 \frac{dx}{\sqrt{1-x}}$ is convergent and is equal to 2.

THEOREM 3. *Let* $f(x)$ *and* $g(x)$ *be continuous functions on* $[a, b)$ *and let the following limit exist:*

$$\lim_{x\to b} \frac{f(x)}{g(x)} = K \qquad (0 < K < \infty).$$

Then both integrals

$$\int_a^b f(x)\,dx, \qquad \int_a^b g(x)\,dx$$

are either convergent or divergent simultaneously.

THEOREM 4. *Let a function* $f(x)$ *be representable in the form*

$$f(x) = \frac{\varphi(x)}{(b-x)^\lambda} \qquad (\lambda > 0),$$

where $\varphi(x)$ *is continuous on* $[a, b]$ *and the condition* $\varphi(b) \ne 0$ *holds.*

Then: (i) if $\lambda < 1$ *and* $\varphi(x) \le c < \infty$, *then the integral* $\int_a^b f(x)\,dx$ *is convergent; (ii) if* $\lambda \ge 1$ *and* $\varphi(x) \ge c > 0$, *then this integral is divergent.*

M7.2.8. Approximate (Numerical) Methods for Computation of Definite Integrals

For approximate computation of an integral like $\int_a^b f(x)\,dx$, let us break up the interval $[a, b]$ into n equal subintervals with length $h = \frac{b-a}{n}$. Introduce the notation: $x_0 = a$, x_1, $\ldots$, $x_n = b$ (the partition points), $y_i = f(x_i)$, $i = 0, 1, \ldots, n$.

1°. *Rectangle rules*:

$$\int_a^b f(x)\,dx \approx h(y_0 + y_1 + \cdots + y_{n-1}),$$

$$\int_a^b f(x)\,dx \approx h(y_1 + y_2 + \cdots + y_n).$$

The error of these formulas, R_n, is proportional to h and is estimated using the inequality

$$|R_n| \le \tfrac{1}{2}h(b-a)M_1, \qquad M_1 = \max_{a\le x\le b}\bigl|f'(x)\bigr|.$$

2°. *Trapezoidal rule*:

$$\int_a^b f(x)\,dx \approx h\Bigl(\frac{y_0 + y_n}{2} + y_1 + y_2 + \cdots + y_{n-1}\Bigr).$$

The error of this formula is proportional to h^2 and is estimated as

$$|R_n| \le \tfrac{1}{12}h^2(b-a)M_2, \qquad M_2 = \max_{a\le x\le b}\bigl|f''(x)\bigr|.$$

3°. *Simpson's rule*:

$$\int_a^b f(x)\,dx \approx \tfrac{1}{3}h[y_0 + y_n + 4(y_1 + y_3 + \cdots + y_{n-1}) + 2(y_2 + y_4 + \cdots + y_{n-2})],$$

where n is even. The error of approximation by Simpson's rule is proportional to h^4:

$$|R_n| \le \tfrac{1}{180}h^4(b-a)M_4, \qquad M_4 = \max_{a\le x\le b}\bigl|f^{(4)}(x)\bigr|.$$

Simpson's rule yields exact results for the case where the integrand function is a polynomial of degree two or three.

M7.3. Double and Triple Integrals

M7.3.1. Definition and Properties of the Double Integral

► **Definition and properties of the double integral.** Suppose there is a bounded set of points defined on the plane, so that it can be placed in a minimal enclosing circle. The diameter of this circle is called the *diameter of the set*. Consider a domain D in the xy-plane. Let us partition D into n nonintersecting subdomains (cells). The largest of the cell diameters is called the *partition diameter* and is denoted $\lambda = \lambda(\mathcal{D}_n)$, where $\mathcal{D}_n$ stands for the partition of the domain D into cells. Let a function $z = f(x, y)$ be defined in D. Select an arbitrary point in each cell (x_i, y_i), $i = 1, 2, \dots, n$, and make up an *integral sum*,

$$s_n = \sum_{i=1}^{n} f(x_i, y_i)\,\Delta S_i,$$

where ΔS_i is the area of the ith subdomain.

If there exists a finite limit, $\mathcal{J}$, of the sums s_n as $\lambda \to 0$ and it depends on neither the partition $\mathcal{D}_n$ nor the selection of the points (x_i, y_i), this limit is denoted $\iint_D f(x, y)\,dx\,dy$ and is called the double integral of the function $f(x, y)$ over the domain D:

$$\iint_D f(x, y)\,dx\,dy = \lim_{\lambda\to 0} s_n.$$

This means that for any $\varepsilon > 0$ there exists a $\delta > 0$ such that for all partitions $\mathcal{D}_n$ such that $\lambda(\mathcal{D}_n) < \delta$ and for any selection of the points (x_i, y_i), the inequality $|s_n - \mathcal{J}| < \varepsilon$ holds. In this case, the function $f(x, y)$ is called integrable over the domain D.

► **Classes of integrable functions.** Further on, it is assumed that D is a closed bounded domain.

1. If $f(x,y)$ is continuous in D, then the double integral $\iint_D f(x,y)\,dx\,dy$ exists.

2. If $f(x,y)$ is bounded and the set of points of discontinuity of $f(x,y)$ has a zero area (e.g., the points of discontinuity lie on finitely many continuous curves in the xy-plane), then the double integral of $f(x,y)$ over the domain D exists.

► **Properties of the double integral.**

1. *Linearity*. If functions $f(x,y)$ and $g(x,y)$ are integrable in D, then

$$\iint_D \bigl[af(x,y) \pm bg(x,y)\bigr]\,dx\,dy = a\iint_D f(x,y)\,dx\,dy \pm b\iint_D g(x,y)\,dx\,dy,$$

where a and b are any numbers.

2. *Additivity*. If the domain D is split into two subdomains D_1 and D_2 that do not have common internal points and if the function $f(x,y)$ is integrable in either subdomain, then

$$\iint_D f(x,y)\,dx\,dy = \iint_{D_1} f(x,y)\,dx\,dy + \iint_{D_2} f(x,y)\,dx\,dy.$$

3. *Estimation theorem*. If $m \le f(x,y) \le M$ in D, then

$$mS \le \iint_D f(x,y)\,dx\,dy \le MS,$$

where S is the area of the domain D.

4. *Mean value theorem*. If $f(x,y)$ is continuous in D, then there exists at least one internal point $(\bar{x},\bar{y}) \in D$ such that

$$\iint_D f(x,y)\,dx\,dy = f(\bar{x},\bar{y})\,S.$$

The number $f(\bar{x},\bar{y})$ is called the *mean value of the function* $f(x,y)$ in D.

5. *Integration of inequalities*. If $\varphi(x,y) \le f(x,y) \le g(x,y)$ in D, then

$$\iint_D \varphi(x,y)\,dx\,dy \le \iint_D f(x,y)\,dx\,dy \le \iint_D g(x,y)\,dx\,dy.$$

In particular, if $f(x,y) \ge 0$ in D, then $\iint_D f(x,y)\,dx\,dy \ge 0$.

6. *Absolute value theorem*

$$\left|\iint_D f(x,y)\,dx\,dy\right| \le \iint_D \bigl|f(x,y)\bigr|\,dx\,dy.$$

► **Geometric meaning of the double integral.** Let a function $f(x,y)$ be nonnegative in D. Then the double integral $\iint_D f(x,y)\,dx\,dy$ is equal to the volume of a cylindrical body with base D in the plane $z=0$ and bounded from above by the surface $z=f(x,y)$; see Fig. M7.4.

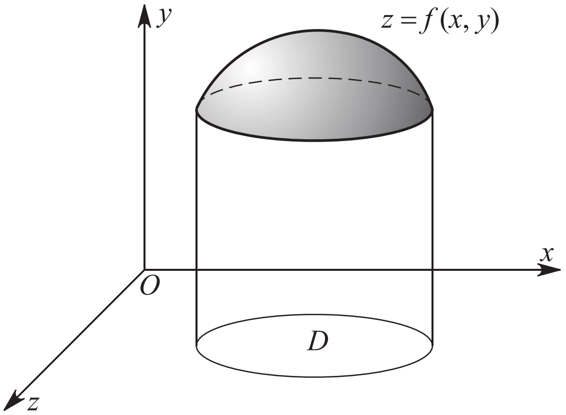

Figure M7.4. A double integral of a nonnegative function $f(x,y)$ over a domain D is equal to the volume of a cylindrical body with base D in the plane $z = 0$ and bounded from above by the surface $z = f(x,y)$.

M7.3.2. Computation of the Double Integral

► Use of iterated integrals.

1°. If a domain D is defined in the xy-plane by the inequalities $a \le x \le b$ and $y_1(x) \le y \le y_2(x)$ (see Fig. M7.5 a), then*

$$\iint_D f(x,y)\,dx\,dy = \int_a^b dx \int_{y_1(x)}^{y_2(x)} f(x,y)\,dy. \qquad \text{(M7.3.2.1)}$$

The expression on the right-hand side is called an *iterated integral*. Note that the variable x in the inner integral is considered constant when integrating.

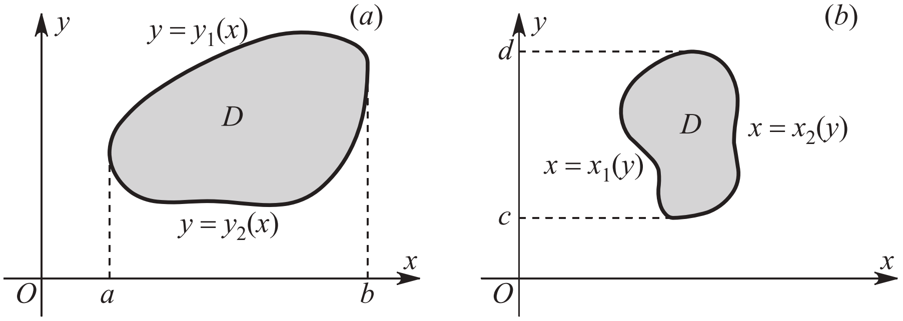

Figure M7.5. Computation of a double integral using iterated integrals: (a) illustration to formula (M7.3.2.1), (b) illustration to formula (M7.3.2.2).

2°. If $D = \{c \le y \le d,\ x_1(y) \le x \le x_2(y)\}$ (see Fig. M7.5 b), then

$$\iint_D f(x,y)\,dx\,dy = \int_c^d dy \int_{x_1(y)}^{x_2(y)} f(x,y)\,dx. \qquad \text{(M7.3.2.2)}$$

Example 1. Compute the integral

$$I = \iint_D \frac{dx\,dy}{(ax+by)^2},$$

where $D = \{0 \le x \le 1,\ 1 \le y \le 3\}$ is a rectangle, $a > 0$, and $b > 0$.

---

* It is assumed that in (M7.3.2.1) and (M7.3.2.2) the double integral on the left-hand side and the inner integral on the right-hand side exist.

Using formula (M7.3.2.2), we get

$$\iint_D \frac{dx\,dy}{(ax+by)^2} = \int_1^3 dy \int_0^1 \frac{dx}{(ax+by)^2}.$$

Compute the inner integral:

$$\int_0^1 \frac{dx}{(ax+by)^2} = -\frac{1}{a(ax+by)}\bigg|_{x=0}^{x=1} = \frac{1}{a}\left(\frac{1}{by} - \frac{1}{by+a}\right).$$

It follows that

$$I = \frac{1}{a}\int_1^3 \left(\frac{1}{by} - \frac{1}{by+a}\right) dy = \frac{1}{ab} \ln \frac{3(a+b)}{a+3b}.$$

3°. Consider a domain D inscribed in a rectangle $\{a \le x \le b,\ c \le y \le d\}$. Let the boundary of D, within the rectangle, be intersected by straight lines parallel to the coordinate axes at two points only, as shown in Fig. M7.6 *a*. Then, by comparing formulas (M7.3.2.1) and (M7.3.2.2), we arrive at the relation

$$\int_a^b dx \int_{y_1(x)}^{y_2(x)} f(x,y)\,dy = \int_c^d dy \int_{x_1(y)}^{x_2(y)} f(x,y)\,dx,$$

which shows how the order of integration can be changed.

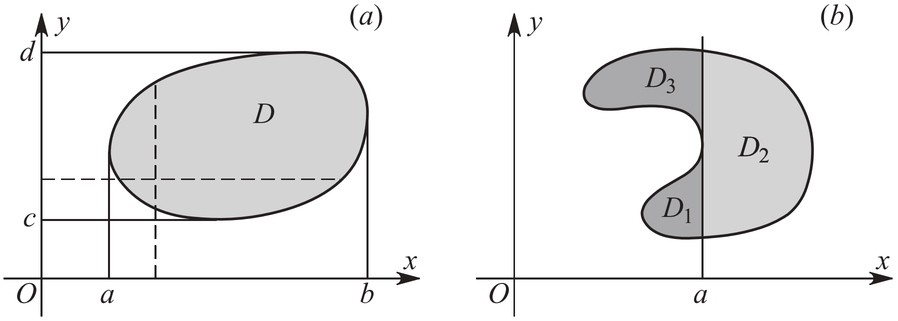

Figure M7.6. Illustrations to the computation of a double integral in a simple (*a*) and a complex (*b*) domain.

4°. In the general case, the domain D is first split into subdomains considered in Items 1° and 2°, and then the property of additivity of the double integral is used. For example, the domain D shown in Fig. M7.6 *b* is divided by the straight line $x = a$ into three subdomains D_1, D_2, and D_3. Then the integral over D is represented as the sum of three integrals over the resulting subdomains.

► Change of variables in the double integral.

1°. Let $x = x(u,v)$ and $y = y(u,v)$ be continuously differentiable functions that map one-to-one a domain D_1 in the uv-plane onto a domain D in the xy-plane, and let $f(x,y)$ be a continuous function in D. Then

$$\iint_D f(x,y)\,dx\,dy = \iint_{D_1} f\bigl(x(u,v),\ y(u,v)\bigr)\,|J(u,v)|\,du\,dv,$$

where $J(u,v)$ is the *Jacobian* (or *Jacobian determinant*) of the mapping of D_1 onto D:

$$J(u,v) = \frac{\partial(x,y)}{\partial(u,v)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \frac{\partial x}{\partial u}\frac{\partial y}{\partial v} - \frac{\partial x}{\partial v}\frac{\partial y}{\partial u}.$$

The fraction before the determinant is a common notation for a Jacobian.

The absolute value of the Jacobian characterizes the extension (contraction) of an infinitesimal area element when passing from x, y to u, v.

2°. The Jacobian of the mapping defining the change from the Cartesian coordinates x, y to the polar coordinates ρ, φ,

$$x = \rho\cos\varphi, \qquad y = \rho\sin\varphi, \tag{M7.3.2.3}$$

is equal to

$$J(\rho,\varphi) = \rho. \tag{M7.3.2.4}$$

Example 2. Given a sphere of radius R and a right circular cylinder of radius $a < R$ whose axis passes through the sphere center, find the volume of the figure the cylinder cuts out of the sphere.

The volume of this figure is calculated as

$$V = 2\iint_{x^2+y^2\le a^2} \sqrt{R^2 - x^2 - y^2}\, dx\, dy.$$

Passing in the integral from x, y to the polar coordinates (M7.3.2.3) and taking into account (M7.3.2.4), we obtain

$$V = 2\int_0^{2\pi}\int_0^a \sqrt{R^2-\rho^2}\,\rho\, d\rho\, d\varphi = \frac{4\pi}{3}\bigl[R^3 - (R^2-a^2)^{3/2}\bigr].$$

M7.3.3. Geometric and Physical Applications of the Double Integral

► Geometric applications of the double integral.

1. *Area of a domain D in the xy-plane*:

$$S = \iint_D dx\, dy.$$

2. *Area of a surface defined by an equation $z = f(x,y)$* with $(x,y) \in D$ (the surface is projected onto a domain D in the xy-plane):

$$S = \iint_D \sqrt{\left(\frac{\partial f}{\partial x}\right)^2 + \left(\frac{\partial f}{\partial y}\right)^2 + 1}\; dx\, dy.$$

3. *Calculation of volumes*. If a domain U of the three-dimensional space is defined by $\bigl\{(x,y) \in D,\ f(x,y) \le z \le g(x,y)\bigr\}$, where D is a domain in the xy-plane, the volume of U is calculated as

$$V = \iint_D \bigl[g(x,y) - f(x,y)\bigr]\, dx\, dy.$$

The three-dimensional domain U is a cylinder with base D bounded by the surface $z = f(x,y)$ from below and the surface $z = g(x,y)$ from above. The lateral surface of this body consists of segments of straight lines parallel to the z-axis.

4. *Area of a surface defined parametrically by equations $x = x(u,v)$, $y = y(u,v)$, $z = z(u,v)$*, with $(u,v) \in D_1$:

$$S = \iint_{D_1} \sqrt{EG - F^2}\, du\, dv.$$

Notation used:

$$E = \left(\frac{\partial x}{\partial u}\right)^2 + \left(\frac{\partial y}{\partial u}\right)^2 + \left(\frac{\partial z}{\partial u}\right)^2,$$

$$G = \left(\frac{\partial x}{\partial v}\right)^2 + \left(\frac{\partial y}{\partial v}\right)^2 + \left(\frac{\partial z}{\partial v}\right)^2,$$

$$F = \frac{\partial x}{\partial u}\frac{\partial x}{\partial v} + \frac{\partial y}{\partial u}\frac{\partial y}{\partial v} + \frac{\partial z}{\partial u}\frac{\partial z}{\partial v}.$$

5. *Area of a surface defined by a vector equation* $\mathbf{r} = \mathbf{r}(u, v) = x(u, v)\,\mathbf{i} + y(u, v)\,\mathbf{j} + z(u, v)\,\mathbf{k}$, with $(u, v) \in D_1$:

$$S = \iint_{D_1} |\mathbf{n}(u, v)|\,du\,dv,$$

where $\mathbf{n}(u, v) = \mathbf{r}_u \times \mathbf{r}_v$ is a normal vector to the surface; the subscripts u and v denote the respective partial derivatives.

Remark. The formulas from Items 4 and 5 are equivalent—they define one and the same surface in two forms, scalar and vector, respectively.

► **Physical applications of the double integral.** Consider a flat plate that occupies a domain D in the xy-plane. Let $\gamma(x, y)$ be the surface density of the plate material (the case $\gamma = \text{const}$ corresponds to a homogeneous plate).

1. *Mass of a flat plate*:

$$m = \iint_D \gamma(x, y)\,dx\,dy.$$

2. *Coordinates of the center of mass of a flat plate*:

$$x_{\rm c} = \frac{1}{m} \iint_D x\gamma(x, y)\,dx\,dy, \qquad y_{\rm c} = \frac{1}{m} \iint_D y\gamma(x, y)\,dx\,dy,$$

where m is the mass of the plate.

3. *Moments of inertia of a flat plate* about the coordinate axes:

$$I_x = \iint_D y^2\gamma(x, y)\,dx\,dy, \qquad I_y = \iint_D x^2\gamma(x, y)\,dx\,dy.$$

The moment of inertia of the plate about the origin of coordinates is calculated as $I_0 = I_x + I_y$.

M7.3.4. Definition and Properties of the Triple Integral

► **Definition of the triple integral.** Let a function $f(x, y, z)$ be defined in a domain U of the three-dimensional space. Let us break up U into n subdomains (cells) that do not have common internal points. Denote by $\lambda = \lambda(\mathcal{U}_n)$ the *diameter* of the resulting partition $\mathcal{U}_n$, i.e., the maximum of the cell diameters (the diameter of a domain in space is the diameter of the minimal sphere enclosing the domain). Select an arbitrary point, (x_i, y_i, z_i), $i = 1,\ 2,\ \dots,\ n$, in each cell and make up an *integral sum*

$$s_n = \sum_{i=1}^{n} f(x_i, y_i, z_i)\,\Delta V_i,$$

where ΔV_i is the volume of the ith cell. If there exists a finite limit of the sums s_n as $\lambda(\mathcal{U}_n) \to 0$ that depends on neither the partition $\mathcal{U}_n$ nor the selection of the points (x_i, y_i, z_i), then it is called the triple integral of the function $f(x, y, z)$ over the domain U and is denoted

$$\iiint_U f(x, y, z)\,dx\,dy\,dz = \lim_{\lambda \to 0} s_n.$$

► **Properties of the triple integral.** The properties of triple integrals are similar to those of double integrals.

1. *Linearity*. If functions $f(x,y,z)$ and $g(x,y,z)$ are integrable in a domain U, then

$$\iiint_U \bigl[af(x,y,z) \pm bg(x,y,z)\bigr]\,dx\,dy\,dz = a\iiint_U f(x,y,z)\,dx\,dy\,dz \pm b\iiint_U g(x,y,z)\,dx\,dy\,dz,$$

where a and b are any numbers.

2. *Additivity*. If a domain U is split into two subdomains, U_1 and U_2, that do not have common internal points and if a function $f(x,y,z)$ is integrable in either subdomain, then

$$\iiint_U f(x,y,z)\,dx\,dy\,dz = \iiint_{U_1} f(x,y,z)\,dx\,dy\,dz + \iiint_{U_2} f(x,y,z)\,dx\,dy\,dz.$$

3. *Estimation theorem*. If $m \le f(x,y,z) \le M$ in a domain U, then

$$mV \le \iiint_U f(x,y,z)\,dx\,dy\,dz \le MV,$$

where V is the volume of U.

4. *Mean value theorem*. If $f(x,y,z)$ is continuous in U, then there exists at least one internal point $(\bar{x},\bar{y},\bar{z}) \in U$ such that

$$\iiint_U f(x,y,z)\,dx\,dy\,dz = f(\bar{x},\bar{y},\bar{z})\,V.$$

The number $f(\bar{x},\bar{y},\bar{z})$ is called the *mean value of the function* f in the domain U.

5. *Integration of inequalities*. If $\varphi(x,y,z) \le f(x,y,z) \le g(x,y,z)$ in a domain U, then

$$\iiint_U \varphi(x,y,z)\,dx\,dy\,dz \le \iiint_U f(x,y,z)\,dx\,dy\,dz \le \iiint_U g(x,y,z)\,dx\,dy\,dz.$$

6. *Absolute value theorem*:

$$\left|\iiint_U f(x,y,z)\,dx\,dy\,dz\right| \le \iiint_U \bigl|f(x,y,z)\bigr|\,dx\,dy\,dz.$$

M7.3.5. Computation of the Triple Integral. Some Applications. Iterated Integrals and Asymptotic Formulas

► **Use of iterated integrals.**

1°. Consider a three-dimensional body U bounded by a surface $z = g(x,y)$ from above and a surface $z = h(x,y)$ from below, with a domain D being the projection of the body onto the xy-plane. In other words, the domain U is defined as $\{(x,y) \in D : h(x,y) \le z \le g(x,y)\}$. Then

$$\iiint_U f(x,y,z)\,dx\,dy\,dz = \iint_D dx\,dy \int_{h(x,y)}^{g(x,y)} f(x,y,z)\,dz.$$

2°. If, under the same conditions as in Item 1°, the domain D of the xy-plane is defined as $\{a \le x \le b,\ y_1(x) \le y \le y_2(x)\}$, then

$$\iiint_U f(x,y,z)\,dx\,dy\,dz = \int_a^b dx \int_{y_1(x)}^{y_2(x)} dy \int_{h(x,y)}^{g(x,y)} f(x,y,z)\,dz.$$

► Change of variables in the triple integral.

1°. Let $x = x(u, v, w)$, $y = y(u, v, w)$, and $z = z(u, v, w)$ be continuously differentiable functions that map, one to one, a domain Ω of the u, v, w space onto a domain U of the x, y, z space, and let a function $f(x, y, z)$ be continuous in U. Then

$$\iiint_U f(x,y,z)\,dx\,dy\,dz = \iiint_\Omega f\bigl(x(u,v,w),\ y(u,v,w),\ z(u,v,w)\bigr)\,|J(u,v,w)|\,du\,dv\,dw,$$

where $J(u, v, w)$ is the *Jacobian* of the mapping of Ω onto U:

$$J(u,v,w) = \frac{\partial(x,y,z)}{\partial(u,v,w)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} & \frac{\partial x}{\partial w} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} & \frac{\partial y}{\partial w} \\ \frac{\partial z}{\partial u} & \frac{\partial z}{\partial v} & \frac{\partial z}{\partial w} \end{vmatrix}.$$

The expression in the middle is a common notation for a Jacobian.

The absolute value of the Jacobian characterizes the expansion (or contraction) of an infinitesimal volume element when passing from x, y, z to u, v, w.

2°. The Jacobians of some common transformations in space are listed in Table M7.2.

TABLE M7.2
Some curvilinear coordinates in space and the respective Jacobians.

Name of coordinates	Transformation	Jacobian, J
Cylindrical coordinates ρ, φ, z	$x = \rho\cos\varphi,\ \ y = \rho\sin\varphi,\ \ z = z$	ρ
Generalized cylindrical coordinates ρ, φ, z	$x = a\rho\cos\varphi,\ \ y = b\rho\sin\varphi,\ \ z = z$	$ab\rho$
Spherical coordinates r, φ, θ	$x = r\cos\varphi\,\sin\theta,\ y = r\sin\varphi\,\sin\theta, z = r\cos\theta$	$r^2\sin\theta$
Generalized spherical coordinates r, φ, θ	$x = ar\cos\varphi\,\sin\theta,\ y = br\sin\varphi\,\sin\theta,$ $z = cr\cos\theta$	$abcr^2\sin\theta$
Parabolic cylinder coordinates σ, τ, z	$x = \sigma\tau,\ \ y = \frac{1}{2}(\tau^2 - \sigma^2),\ \ z = z$	$\sigma^2 + \tau^2$

► Some geometric and physical applications of the triple integral.

1. *Volume of a domain* U:

$$V = \iiint_U dx\,dy\,dz.$$

2. *Mass of a body of variable density* $\gamma = \gamma(x, y, z)$ occupying a domain U:

$$m = \iiint_U \gamma\,dx\,dy\,dz.$$

3. *Coordinates of the center of mass*:

$$x_{\rm c} = \frac{1}{m}\iiint_U x\gamma\,dx\,dy\,dz, \quad y_{\rm c} = \frac{1}{m}\iiint_U y\gamma\,dx\,dy\,dz, \quad z_{\rm c} = \frac{1}{m}\iiint_U z\gamma\,dx\,dy\,dz.$$

4. *Moments of inertia* about the coordinate axes:

$$I_x = \iiint_U \rho_{yz}^2\gamma\,dx\,dy\,dz, \quad I_y = \iiint_U \rho_{xz}^2\gamma\,dx\,dy\,dz, \quad I_z = \iiint_U \rho_{xy}^2\gamma\,dx\,dy\,dz,$$

where $\rho_{yz}^2 = y^2 + z^2$, $\rho_{xz}^2 = x^2 + z^2$, and $\rho_{xy}^2 = x^2 + y^2$.

If the body is homogeneous, then $\gamma = \text{const}$.

Example. Given a bounded homogeneous elliptic cylinder,

$$\frac{x^2}{a^2}+\frac{y^2}{b^2}=1,\qquad 0\le z\le h,$$

find its moment of inertia about the z-axis.

Using the generalized cylindrical coordinates (see the second row in Table M7.2), we obtain

$$\begin{aligned}I_x&=\gamma\iiint_U(x^2+y^2)\,dx\,dy\,dz=\gamma\int_0^h\int_0^{2\pi}\int_0^1\rho^2(a^2\cos^2\varphi+b^2\sin^2\varphi)ab\rho\,d\rho\,d\varphi\,dz\\&=\frac{1}{4}ab\gamma\int_0^h\int_0^{2\pi}(a^2\cos^2\varphi+b^2\sin^2\varphi)\,d\varphi\,dz=\frac{1}{4}ab\gamma\int_0^{2\pi}\int_0^h(a^2\cos^2\varphi+b^2\sin^2\varphi)\,dz\,d\varphi\\&=\frac{1}{4}abh\gamma\int_0^{2\pi}(a^2\cos^2\varphi+b^2\sin^2\varphi)\,d\varphi=\frac{1}{4}\pi ab(a^2+b^2)h\gamma.\end{aligned}$$

5. *Potential of the gravitational field* of a body U at a point (x,y,z):

$$\Phi(x,y,z)=\iiint_U\gamma(\xi,\eta,\zeta)\frac{d\xi\,d\eta\,d\zeta}{r},\qquad r=\sqrt{(x-\xi)^2+(y-\eta)^2+(z-\zeta)^2},$$

where $\gamma=\gamma(\xi,\eta,\zeta)$ is the body density. A material point of mass m is pulled by the gravitating body U with a force **F**. The projections of **F** onto the x-, y-, and z-axes are given, respectively, by

$$\begin{aligned}F_x&=km\frac{\partial\Phi}{\partial x}=km\iiint_U\gamma(\xi,\eta,\zeta)\frac{\xi-x}{r^3}\,d\xi\,d\eta\,d\zeta,\\F_y&=km\frac{\partial\Phi}{\partial y}=km\iiint_U\gamma(\xi,\eta,\zeta)\frac{\eta-y}{r^3}\,d\xi\,d\eta\,d\zeta,\\F_z&=km\frac{\partial\Phi}{\partial z}=km\iiint_U\gamma(\xi,\eta,\zeta)\frac{\zeta-z}{r^3}\,d\xi\,d\eta\,d\zeta,\end{aligned}$$

where k is the gravitational constant.

M7.4. Line and Surface Integrals

M7.4.1. Line Integral of the First Kind

► **Definition of the line integral of the first kind.** Let a function $f(x,y,z)$ be defined on a piecewise smooth curve $\overset{\smile}{AB}$ in the three-dimensional space $\mathbb{R}^3$. Let the curve $\overset{\smile}{AB}$ be divided into n subcurves by points $A=M_0$, M_1, M_2, …, $M_n=B$, thus defining a partition $\mathcal{L}_n$. The longest of the chords M_0M_1, M_1M_2, …, $M_{n-1}M_n$ is called the *diameter of the partition* $\mathcal{L}_n$ and is denoted $\lambda=\lambda(\mathcal{L}_n)$. Let us select on each arc $\overset{\smile}{M_{i-1}M_i}$ an arbitrary point (x_i,y_i,z_i), $i=1$, 2, …, n, and make up an *integral sum*

$$s_n=\sum_{i=1}^{n}f(x_i,y_i,z_i)\,\Delta l_i,$$

where Δl_i is the length of $\overset{\smile}{M_{i-1}M_i}$.

If there exists a finite limit of the sums s_n as $\lambda(\mathcal{L}_n)\to 0$ that depends on neither the partition $\mathcal{L}_n$ nor the selection of the points (x_i,y_i,z_i), then it is called the *line integral of the first kind* of the function $f(x,y,z)$ over the curve $\overset{\smile}{AB}$ and is denoted

$$\int_{AB}f(x,y,z)\,dl=\lim_{\lambda\to 0}s_n.$$

A line integral is also called a *curvilinear integral* or a *path integral*.

If the function $f(x,y,z)$ is continuous, then the line integral exists. The line integral of the first kind does not depend of the direction the path $\overset{\smile}{AB}$ is traced; its properties are similar to those of the definite integral.

► Computation of the line integral of the first kind.

1. If a plane curve is defined in the form $y = y(x)$, with $x \in [a, b]$, then

$$\int_{AB} f(x,y)\,dl = \int_a^b f\bigl(x, y(x)\bigr)\sqrt{1 + (y'_x)^2}\,dx.$$

2. If a curve $\overset{\smile}{AB}$ is defined in parametric form by equations $x = x(t)$, $y = y(t)$, and $z = z(t)$, with $t \in [\alpha, \beta]$, then

$$\int_{AB} f(x,y,z)\,dl = \int_\alpha^\beta f\bigl(x(t), y(t), z(t)\bigr)\sqrt{(x'_t)^2 + (y'_t)^2 + (z'_t)^2}\,dt. \qquad \text{(M7.4.1.1)}$$

If a function $f(x,y)$ is defined on a plane curve $x = x(t)$, $y = y(t)$, with $t \in [\alpha, \beta]$, one should set $z'_t = 0$ in (M7.4.1.1).

Example. Evaluate the integral $\displaystyle\int_{AB} xy\,dl$, where $\overset{\smile}{AB}$ is a quarter of an ellipse with semiaxes a and b.

Let us write out the equations of the ellipse for the first quadrant in parametric form:

$$x = a\cos t, \qquad y = b\sin t \qquad (0 \le t \le \pi/2).$$

We have $\sqrt{(x'_t)^2 + (y'_t)^2} = \sqrt{a^2\sin^2 t + b^2\cos^2 t}$. To evaluate the integral, we use formula (M7.4.1.1) with $z'_t = 0$:

$$\begin{aligned}\int_{AB} xy\,dl &= \int_0^{\pi/2} (a\cos t)\,(b\sin t)\sqrt{a^2\sin^2 t + b^2\cos^2 t}\,dt\\ &= \frac{ab}{2}\int_0^{\pi/2}\sin 2t\sqrt{\frac{a^2}{2}(1-\cos 2t) + \frac{b^2}{2}(1+\cos 2t)}\,dt = \frac{ab}{4}\int_{-1}^1\sqrt{\frac{a^2+b^2}{2} + \frac{b^2-a^2}{2}u}\,du\\ &= \frac{ab}{4}\,\frac{2}{b^2-a^2}\,\frac{2}{3}\left(\frac{a^2+b^2}{2} + \frac{b^2-a^2}{2}u\right)^{3/2}\Bigg|_{-1}^{1} = \frac{ab}{3}\,\frac{a^2+ab+b^2}{a+b}.\end{aligned}$$

► Applications of the line integral of the first kind.

1. *Length of a curve* $\overset{\smile}{AB}$:

$$L = \int_{AB} dl.$$

2. *Mass of a material curve* $\overset{\smile}{AB}$ with a given line density $\gamma = \gamma(x,y,z)$:

$$m = \int_{AB} \gamma\,dl.$$

3. *Coordinates of the center of mass* of a material curve $\overset{\smile}{AB}$:

$$x_{\rm c} = \frac{1}{m}\int_{AB} x\gamma\,dl, \quad y_{\rm c} = \frac{1}{m}\int_{AB} y\gamma\,dl, \quad z_{\rm c} = \frac{1}{m}\int_{AB} z\gamma\,dl.$$

To a material line with uniform density there corresponds $\gamma = \text{const}$.

M7.4.2. Line Integral of the Second Kind

► **Definition of the line integral of the second kind.** Let a vector field

$$\mathbf{a}(x,y,z) = P(x,y,z)\,\mathbf{i} + Q(x,y,z)\,\mathbf{j} + R(x,y,z)\,\mathbf{k}$$

and a piecewise smooth curve $\smile{AB}$ be defined in some domain in $\mathbb{R}^3$. By dividing the curve by points $A = M_0$, M_1, M_2, $\ldots$, $M_n = B$ into n subcurves, we obtain a partition $\mathcal{L}_n$. Let us select on each arc $\overset{\smile}{M_{i-1}M_i}$ an arbitrary point (x_i, y_i, z_i), $i = 1, 2, \ldots, n$, and make up a sum of dot products

$$s_n = \sum_{i=1}^{n} \mathbf{a}(x_i, y_i, z_i) \cdot \overrightarrow{M_{i-1}M_i},$$

called an *integral sum*.

If there exists a finite limit of the sums s_n as $\lambda(\mathcal{L}_n) \to 0$ (λ is the diameter of the partition; see Subsection M7.4.1) that depends on neither the partition $\mathcal{L}_n$ nor the selection of the points (x_i, y_i, z_i), then it is called the *line integral of the second kind* of the vector field $\mathbf{a}(x,y,z)$ along the curve $\overset{\smile}{AB}$ and is denoted

$$\int_{AB} \mathbf{a}\cdot d\mathbf{r}, \quad \text{or} \quad \int_{AB} P\,dx + Q\,dy + R\,dz.$$

The line integral of the second kind depends on the direction the path is traced, so that

$$\int_{AB} \mathbf{a}\cdot d\mathbf{r} = -\int_{BA} \mathbf{a}\cdot d\mathbf{r}.$$

A line integral over a closed contour $\mathcal{C}$ is called a *closed path integral* (or a *circulation*) of a vector field $\mathbf{a}$ around $\mathcal{C}$ and is denoted

$$\oint_{\mathcal{C}} \mathbf{a}\cdot d\mathbf{r}.$$

Physical meaning of the line integral of the second kind: $\int_{AB} \mathbf{a}\cdot d\mathbf{r}$ determines the work done by the vector field $\mathbf{a}(x,y,z)$ on a particle of unit mass when it travels along the arc $\overset{\smile}{AB}$.

► **Computation of the line integral of the second kind.**

1°. For a plane curve $\overset{\smile}{AB}$ defined as $y = y(x)$, with $x \in [a, b]$, and a plane vector field $\mathbf{a}$, we have

$$\int_{AB} \mathbf{a}\cdot d\mathbf{r} = \int_a^b \bigl[P\bigl(x, y(x)\bigr) + Q\bigl(x, y(x)\bigr)y'_x(x)\bigr]\,dx.$$

2°. Let $\overset{\smile}{AB}$ be defined by a vector equation $\mathbf{r} = \mathbf{r}(t) = x(t)\mathbf{i} + y(t)\mathbf{j} + z(t)\mathbf{k}$, with $t \in [\alpha, \beta]$. Then

$$\begin{aligned}\int_{AB} \mathbf{a}\cdot d\mathbf{r} &= \int_{AB} P\,dx + Q\,dy + R\,dz\\ &= \int_\alpha^\beta \bigl[P\bigl(x(t), y(t), z(t)\bigr)x'_t(t) + Q\bigl(x(t), y(t), z(t)\bigr)y'_t(t) + R\bigl(x(t), y(t), z(t)\bigr)z'_t(t)\bigr]\,dt. \qquad \text{(M7.4.2.1)}\end{aligned}$$

For a plane curve $\overset{\smile}{AB}$ and a plane vector field $\mathbf{a}$, one should set $z'(t) = 0$ in (M7.4.2.1).

► **Potential and curl of a vector field.**

1°. A vector field $\mathbf{a} = \mathbf{a}(x, y, z)$ is called *potential* if there exists a function $\Phi(x, y, z)$ such that

$$\mathbf{a} = \operatorname{grad}\Phi, \quad \text{or} \quad \mathbf{a} = \frac{\partial\Phi}{\partial x}\mathbf{i} + \frac{\partial\Phi}{\partial y}\mathbf{j} + \frac{\partial\Phi}{\partial z}\mathbf{k}.$$

The function $\Phi(x, y, z)$ is called a *potential* of the vector field $\mathbf{a}$. The line integral of the second kind of a potential vector field along a path $\breve{AB}$ is equal to the increment of the potential along the path:

$$\int_{AB} \mathbf{a}\cdot d\mathbf{r} = \Phi\big|_B - \Phi\big|_A.$$

2°. The *curl* of a vector field $\mathbf{a}(x, y, z) = P\mathbf{i} + Q\mathbf{j} + R\mathbf{k}$ is the vector defined as

$$\operatorname{curl}\mathbf{a} = \left(\frac{\partial R}{\partial y} - \frac{\partial Q}{\partial z}\right)\mathbf{i} + \left(\frac{\partial P}{\partial z} - \frac{\partial R}{\partial x}\right)\mathbf{j} + \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y}\right)\mathbf{k} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ P & Q & R \end{vmatrix}.$$

The vector $\operatorname{curl}\mathbf{a}$ characterizes the rate of rotation of $\mathbf{a}$ and can also be described as the circulation density of $\mathbf{a}$. Alternative notations: $\operatorname{curl}\mathbf{a} \equiv \nabla\times\mathbf{a} \equiv \operatorname{curl}\mathbf{a}$.

► **Necessary and sufficient conditions for a vector field to be potential.** Let U be a simply connected domain in $\mathbb{R}^3$ (i.e., a domain in which any closed contour can be deformed to a point without leaving U) and let $\mathbf{a}(x, y, z)$ be a vector field in U. Then the following four assertions are equivalent to each other:

(1) the vector field $\mathbf{a}$ is potential;

(2) $\operatorname{curl}\mathbf{a} \equiv \mathbf{0}$;

(3) the circulation of $\mathbf{a}$ around any closed contour $\mathcal{C} \in U$ is zero, or, equivalently, $\oint_{\mathcal{C}} \mathbf{a}\cdot d\mathbf{r} = 0$;

(4) the integral $\int_{AB} \mathbf{a}\cdot d\mathbf{r}$ is independent of the shape of $\breve{AB} \in U$ (it depends only on the initial and final points).

M7.4.3. Surface Integral of the First Kind

► **Definition of the surface integral of the first kind.** Let a function $f(x, y, z)$ be defined on a smooth surface D. Let us break up this surface into n elements (cells) that do not have common internal points and let us denote this partition by $\mathcal{D}_n$. The *diameter*, $\lambda(\mathcal{D}_n)$, of a partition $\mathcal{D}_n$ is the largest of the diameters of the cells (see Paragraph M7.3.4-1). Let us select in each cell an arbitrary point (x_i, y_i, z_i), $i = 1, 2, \ldots, n$, and make up an *integral sum*

$$s_n = \sum_{i=1}^{n} f(x_i, y_i, z_i)\,\Delta S_i,$$

where ΔS_i is the area of the ith element.

If there exists a finite limit of the sums s_n as $\lambda(\mathcal{D}_n) \to 0$ that depends on neither the partition $\mathcal{D}_n$ nor the selection of the points (x_i, y_i, z_i), then it is called the *surface integral of the first kind* of the function $f(x, y, z)$ and is denoted $\iint_D f(x, y, z)\,dS$.

► **Computation of the surface integral of the first kind.**

1°. If a surface D is defined by an equation $z = z(x, y)$, with $(x, y) \in D_1$, then

$$\iint_D f(x, y, z)\, dS = \iint_{D_1} f\bigl(x, y, z(x, y)\bigr) \sqrt{1 + (z'_x)^2 + (z'_y)^2}\, dx\, dy.$$

2°. If a surface D is defined by a vector equation $\mathbf{r} = \mathbf{r}(x, y, z) = x(u, v)\, \mathbf{i} + y(u, v)\, \mathbf{j} + z(u, v)\, \mathbf{k}$, where $(u, v) \in D_2$, then

$$\iint_D f(x, y, z)\, dS = \iint_{D_2} f\bigl(x(u, v), y(u, v), z(u, v)\bigr)\, |\mathbf{n}(u, v)|\, du\, dv,$$

where $\mathbf{n}(u, v) = \mathbf{r}_u \times \mathbf{r}_v$ is a normal to the surface D; the subscripts u and v denote the respective partial derivatives.

► **Applications of the surface integral of the first kind.**

1°. Area of a surface D:

$$S_D = \iint_D dS.$$

2°. Mass of a material surface D with a surface density $\gamma = \gamma(x, y, z)$:

$$m = \iint_D \gamma(x, y, z)\, dS.$$

3°. Coordinates of the center of mass of a material surface D:

$$x_{\rm c} = \frac{1}{m} \iint_D x\gamma\, dS, \quad y_{\rm c} = \frac{1}{m} \iint_D y\gamma\, dS, \quad z_{\rm c} = \frac{1}{m} \iint_D z\gamma\, dS.$$

To the uniform surface density there corresponds $\gamma = \text{const}$.

M7.4.4. Surface Integral of the Second Kind

► **Definition of the surface integral of the second kind.** Let a vector field $\mathbf{a}(x, y, z) = P\, \mathbf{i} + Q\, \mathbf{j} + R\, \mathbf{k}$ be defined on a smooth oriented surface D. Let us perform a partition, $\mathcal{D}_n$, of the surface D into n elements (cells) that do not have common internal points. Also select an arbitrary point $M_i(x_i, y_i, z_i)$, $i = 1, 2, \ldots, n$, for each cell and make up an *integral sum* $s_n = \sum\limits_{i=1}^{n} \mathbf{a}(x_i, y_i, z_i) \cdot \mathbf{n}_i^\circ\, \Delta S_i$, where ΔS_i is area of the ith cell and $\mathbf{n}_i^\circ$ is the unit normal to the surface at the point M_i, the orientation of which coincides with that of the surface.

If there exists a finite limit of the sums s_n as $\lambda(\mathcal{D}_n) \to 0$ (λ is the diameter of the partition, see Subsection M7.4.3) that depends on neither the partition $\mathcal{D}_n$ nor the selection of the points $M_i(x_i, y_i, z_i)$, then it is called the *surface integral of the second kind* (or the *flux of the vector field* **a** *across the oriented surface* D) and is denoted

$$\iint_D \mathbf{a}(x, y, z) \cdot \overrightarrow{dS}, \quad \text{or} \quad \iint_D P\, dy\, dz + Q\, dx\, dz + R\, dx\, dy.$$

Note that the surface integral of the second kind changes its sign when the orientation of the surface is reversed.

► **Computation of the surface integral of the second kind.**

1°. If a surface D is defined by an equation $z = z(x, y)$, with $(x, y) \in D_2$, then the normal $\mathbf{n}(x, y) = \mathbf{r}_x \times \mathbf{r}_y = -z_x\mathbf{i} - z_y\mathbf{j} + \mathbf{k}$ orients the surface D "upward," in the positive direction of the z-axis; the subscripts x and y denote the respective partial derivatives. Then

$$\iint_D \mathbf{a} \cdot \overrightarrow{dS} = \pm \iint_{D_2} \bigl(-z_x P - z_y Q + R\bigr)\, dx\, dy,$$

where $P = P\bigl(x, y, z(x, y)\bigr)$, $Q = Q\bigl(x, y, z(x, y)\bigr)$, and $R = R\bigl(x, y, z(x, y)\bigr)$. The plus sign is taken if the surface has the "upward" orientation, and the minus sign is chosen in the opposite case.

M7.4.5. Integral Formulas of Vector Calculus

► **Ostrogradsky–Gauss theorem (divergence theorem).** Let a vector field $\mathbf{a}(x, y, z) = P(x, y, z)\,\mathbf{i} + Q(x, y, z)\,\mathbf{j} + R(x, y, z)\,\mathbf{k}$ be continuously differentiable in a finite simply connected domain $V \subset \mathbb{R}^3$ and let S denote the surface of V oriented by an outward normal. Then the *Ostrogradsky–Gauss theorem* (or the *divergence theorem*) holds:

$$\iint_S \mathbf{a} \cdot \overrightarrow{dS} = \iiint_V \operatorname{div} \mathbf{a}\; dx\, dy\, dz,$$

where div **a** is the *divergence* of the vector **a**, which is defined as follows:

$$\operatorname{div} \mathbf{a} = \frac{\partial P}{\partial x} + \frac{\partial Q}{\partial y} + \frac{\partial R}{\partial z}.$$

Thus, the flux of a vector field across a closed surface in the outward direction is equal to the triple integral of the divergence of the vector field over the volume bounded by the surface. In coordinate form, the Ostrogradsky–Gauss theorem reads

$$\iint_S P\, dy\, dz + Q\, dx\, dz + R\, dx\, dy = \iiint_V \left(\frac{\partial P}{\partial x} + \frac{\partial Q}{\partial y} + \frac{\partial R}{\partial z}\right) dx\, dy\, dz.$$

► **Stokes's theorem (curl theorem).**

1°. Let a vector field $\mathbf{a}(x, y, z)$ be continuously differentiable in a domain of the three-dimensional space $\mathbb{R}^3$ that contains an oriented surface D. The orientation of a surface uniquely defines the direction in which the boundary of the surface is traced; specifically, the boundary is traced counterclockwise when looked at from the direction of the normal to the surface. Then the circulation of the vector field around the boundary $\mathcal{C}$ of the surface D is equal to the flux of the vector curl **a** across D:

$$\oint_{\mathcal{C}} \mathbf{a} \cdot d\mathbf{r} = \iint_D \operatorname{curl} \mathbf{a} \cdot \overrightarrow{dS}.$$

In coordinate notation, *Stokes's theorem* reads

$$\oint_{\mathcal{C}} P\, dx + Q\, dy + R\, dz = \iint_D \left(\frac{\partial R}{\partial y} - \frac{\partial Q}{\partial z}\right) dy\, dz + \left(\frac{\partial P}{\partial z} - \frac{\partial R}{\partial x}\right) dx\, dz + \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y}\right) dx\, dy.$$

2°. For a plane vector field $\mathbf{a}(x, y) = P(x, y)\,\mathbf{i} + Q(x, y)\,\mathbf{j}$, Stokes's theorem reduces to *Green's theorem*:

$$\oint_{\mathcal{C}} P\, dx + Q\, dy = \iint_D \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y}\right) dx\, dy,$$

where the contour $\mathcal{C}$ of the domain D on the xy-plane is traced counterclockwise.

Chapter M8

Series

M8.1. Numerical Series and Infinite Products

M8.1.1. Convergent Numerical Series and Their Properties. Cauchy's Criterion

► **Basic definitions.** Let $\{a_n\}$ be a numerical sequence. The expression

$$a_1 + a_2 + \cdots + a_n + \cdots = \sum_{n=1}^{\infty} a_n$$

is called a *numerical series* (*infinite sum*, *infinite numerical series*), a_n is the *generic term of the series*, and

$$s_n = a_1 + a_2 + \cdots + a_n = \sum_{k=1}^{n} a_k$$

is the *nth partial sum of the series*. If there exists a finite limit $\lim\limits_{n\to\infty} s_n = S$, the series is called *convergent*, and S is called the *sum of the series*. In this case, one writes $\sum\limits_{n=1}^{\infty} a_n = S$. If $\lim\limits_{n\to\infty} s_n$ does not exist (or is infinite), the series is called *divergent*. The series $a_{n+1} + a_{n+2} + a_{n+3} + \cdots$ is called the *nth remainder of the series*.

Example 1. Consider the series $\sum\limits_{n=1}^{\infty} aq^{n-1} = a + aq + aq^2 + \cdots$ whose terms form a *geometric progression* with ratio q. This series is convergent for $|q| < 1$ (its sum has the form $S = \frac{a}{1-q}$) and is divergent for $|q| \ge 1$.

► **Necessary condition for a series to be convergent. Cauchy's criterion.**

1. *A necessary condition for a series to be convergent.* For a convergent series $\sum\limits_{n=1}^{\infty} a_n$, the generic term must tend to zero, $\lim\limits_{n\to\infty} a_n = 0$. If $\lim\limits_{n\to\infty} a_n \ne 0$, then the series is divergent.

Example 2. The series $\sum\limits_{n=1}^{\infty} \cos\dfrac{1}{n}$ is divergent, since its generic term $a_n = \cos\dfrac{1}{n}$ does not tend to zero as $n \to \infty$.

The above necessary condition is insufficient for the convergence of a series.

Example 3. Consider the series $\sum\limits_{n=1}^{\infty} \dfrac{1}{\sqrt{n}}$. Its generic term tends to zero, $\lim\limits_{n\to\infty} \dfrac{1}{\sqrt{n}} = 0$, but the series $\sum\limits_{n=1}^{\infty} \dfrac{1}{\sqrt{n}}$ is divergent because its partial sums are unbounded,

$$s_n = \frac{1}{\sqrt{1}} + \frac{1}{\sqrt{2}} + \cdots + \frac{1}{\sqrt{n}} > n\frac{1}{\sqrt{n}} = \sqrt{n} \to \infty \quad \text{as} \quad n \to \infty.$$

2. *Cauchy's criterion of convergence of a series.* A series $\sum\limits_{n=1}^{\infty} a_n$ is convergent if and only if for any $\varepsilon > 0$ there exists an $N = N(\varepsilon)$ such that for all $n > N$ and any positive integer k, the following inequality holds: $|a_{n+1} + \cdots + a_{n+k}| < \varepsilon$.

► **Properties of convergent series.**

1. If a series is convergent, then any of its remainders is convergent. Removal or addition of finitely many terms does not affect the convergence of a series.

2. If all terms of a series are multiplied by a nonzero constant, the resulting series preserves the property of convergence or divergence (its sum is multiplied by that constant).

3. If the series $\sum\limits_{n=1}^{\infty} a_n$ and $\sum\limits_{n=1}^{\infty} b_n$ are convergent and their sums are equal to S_1 and S_2, respectively, then the series $\sum\limits_{n=1}^{\infty}(a_n \pm b_n)$ are convergent and their sums are equal to $S_1 \pm S_2$.

4. Terms of a convergent series can be grouped in successive order; the resulting series has the same sum. In other words, one can insert brackets inside a series in an arbitrary order. The inverse operation of opening brackets is not always admissible. Thus, the series $(1-1)+(1-1)+\cdots$ is convergent (its sum is equal to zero), but, after removing the brackets, we obtain the divergent series $1-1+1-1+\cdots$ (its generic term does not tend to zero).

M8.1.2. Convergence Criteria for Series with Positive (Nonnegative) Terms

► **Basic convergence (divergence) criteria for series with positive terms.**

1. *The first comparison criterion.* If $0 \le a_n \le b_n$ (starting from some n), then the convergence of the series $\sum\limits_{n=1}^{\infty} b_n$ implies the convergence of $\sum\limits_{n=1}^{\infty} a_n$; and the divergence of the series $\sum\limits_{n=1}^{\infty} a_n$ implies the divergence of $\sum\limits_{n=1}^{\infty} b_n$.

2. *The second convergence criterion.* Suppose that there exists a finite limit

$$\lim_{n\to\infty} \frac{a_n}{b_n} = \sigma,$$

where $0 < \sigma < \infty$. Then $\sum\limits_{n=1}^{\infty} a_n$ is convergent (resp., divergent) if and only if $\sum\limits_{n=1}^{\infty} b_n$ is convergent (resp., divergent).

Corollary. Suppose that $a_{n+1}/a_n \le b_{n+1}/b_n$ starting from some N (i.e., for $n > N$). Then convergence of the series $\sum\limits_{n=1}^{\infty} b_n$ implies convergence of $\sum\limits_{n=1}^{\infty} a_n$, and divergence of $\sum\limits_{n=1}^{\infty} a_n$ implies divergence of $\sum\limits_{n=1}^{\infty} b_n$.

3. *D'Alembert criterion.* Suppose that there exists the limit (finite or infinite)

$$\lim_{n\to\infty} \frac{a_{n+1}}{a_n} = D.$$

If $D < 1$, then the series $\sum\limits_{n=1}^{\infty} a_n$ is convergent. If $D > 1$, then the series is divergent. For $D = 1$, the d'Alembert criterion cannot be used for deciding whether the series is convergent or divergent.

Example 1. Let us examine the convergence of the series $\sum\limits_{n=1}^{\infty} n^k x^n$ with $x > 0$, using the d'Alembert criterion. Taking $a_n = n^k x^n$, we get

$$\frac{a_{n+1}}{a_n} = \left(1 + \frac{1}{n}\right)^k x \to x \quad \text{as} \quad n \to \infty.$$

Therefore, $D = x$. It follows that the series is convergent for $x < 1$ and divergent for $x > 1$. The series is divergent for $x = 1$, since a_n does not tend to zero as $n \to \infty$.

4. *Cauchy criterion.* Suppose that there exists the limit (finite or infinite)

$$\lim_{n\to\infty} \sqrt[n]{a_n} = K.$$

For $K < 1$, the series $\sum\limits_{n=1}^{\infty} a_n$ is convergent; for $K > 1$, the series is divergent. For $K = 1$, the Cauchy criterion cannot be used to establish convergence of a series.

Remark. The Cauchy criterion is stronger than the d'Alembert criterion, but the latter is, in many cases, simpler than the former.

5. *Gauss's criterion.* Suppose that the ratio of two consecutive terms of a series can be represented in the form

$$\frac{a_n}{a_{n+1}} = \lambda + \frac{\mu}{n} + o\left(\frac{1}{n}\right) \quad \text{as} \quad n \to \infty.$$

The series $\sum\limits_{n=1}^{\infty} a_n$ is convergent if $\lambda > 1$ or if $\lambda = 1$ and $\mu > 1$. The series is divergent if $\lambda < 1$ or if $\lambda = 1$ and $\mu \le 1$.

6. *Maclaurin–Cauchy integral criterion.* Let $f(x)$ be a nonnegative nonincreasing continuous function on the interval $1 \le x < \infty$. Let $f(1) = a_1$, $f(2) = a_2$, $\dots$, $f(n) = a_n$, $\dots$ Then the series $\sum\limits_{n=1}^{\infty} a_n$ is convergent if and only if the improper integral $\int_1^{\infty} f(x)\,dx$ is convergent.

Example 2. The *harmonic series* $\sum\limits_{n=1}^{\infty} \frac{1}{n} = 1 + \frac{1}{2} + \frac{1}{3} + \cdots$ is divergent, since the integral $\int_1^{\infty} \frac{1}{x}\,dx$ is divergent. In a similar way, one finds that the series $\sum\limits_{n=1}^{\infty} \frac{1}{n^{\alpha}}$ is convergent for $\alpha > 1$ and divergent for $\alpha \le 1$.

M8.1.3. Convergence Criteria for Arbitrary Numerical Series. Absolute and Conditional Convergence

▶ Arbitrary series. Leibniz, Abel, and Dirichlet convergence criteria.

1. *Leibniz criterion.* Suppose that the terms a_n of a series $\sum\limits_{n=1}^{\infty} a_n$ have alternating signs, their absolute values form a nonincreasing sequence, and $a_n \to 0$ as $n \to \infty$. Then this "alternating" series is convergent. If S is the sum of the series and s_n is its nth partial sum, then the following inequality holds for the error $|S - s_n| \le |a_{n+1}|$.

Example 1. The series $1 - \frac{1}{2^2} + \frac{1}{3^3} - \frac{1}{4^4} + \frac{1}{5^5} - \cdots$ is convergent by the Leibniz criterion. Taking $S \approx s_4 = 1 - \frac{1}{2^2} + \frac{1}{3^3} - \frac{1}{4^4}$, we obtain the error less than $a_5 = \frac{1}{5^5} = 0.00032$.

2. *Abel criterion.* Consider the series

$$\sum_{n=1}^{\infty} a_n b_n = a_1 b_1 + a_2 b_2 + \cdots + a_n b_n + \cdots, \qquad \text{(M8.1.3.1)}$$

where a_n and b_n are two sequences or real numbers.

Series (M8.1.3.1) is convergent if the series

$$\sum_{n=1}^{\infty} b_n = b_1 + b_2 + \cdots + b_n + \cdots \qquad \text{(M8.1.3.2)}$$

is convergent and the a_n form a bounded monotone sequence ($|a_n| < K$).

3. *Dirichlet criterion.* Series (M8.1.3.1) is convergent if partial sums of series (M8.1.3.2) are bounded uniformly in n,

$$\left|\sum_{k=1}^{n} b_k\right| \le M \qquad (n = 1,\, 2,\, \dots),$$

and the sequence $a_n \to 0$ is monotone.

Example 2. Consider the series $\sum\limits_{n=1}^{\infty} a_n \sin(nx)$, where $a_n \to 0$ is a monotonically decreasing sequence. Taking $b_n = \sin(nx)$ and using a well-known identity, we find the partial sum

$$s_n = \sum_{k=1}^{n} \sin(kx) = \frac{\cos\left(\frac{1}{2}x\right) - \cos\left[\left(n + \frac{1}{2}\right)x\right]}{2\sin\left(\frac{1}{2}x\right)} \qquad (x \ne 2m\pi;\ \ m = 0, \pm1, \pm2, \dots).$$

This sum is bounded for $x \ne 2m\pi$:

$$|s_n| \le \frac{1}{\left|\sin\left(\frac{1}{2}x\right)\right|}.$$

Therefore, by the Dirichlet criterion, the series $\sum\limits_{n=1}^{\infty} a_n \sin(nx)$ is convergent for any $x \ne 2m\pi$. Direct verification shows that this series is also convergent for $x = 2m\pi$ (since all its terms at these points are equal to zero).

Remark. The Leibniz and the Abel criteria can be deduced from the Dirichlet criterion.

► Absolute and conditional convergence.

1. *Absolutely convergent series.* A series $\sum\limits_{n=1}^{\infty} a_n$ (with terms of arbitrary sign) is called *absolutely convergent* if the series $\sum\limits_{n=1}^{\infty} |a_n|$ is convergent.

Any absolutely convergent series is convergent. In order to establish absolute convergence of a series, one can use all convergence criteria for series with nonnegative terms given in Subsection M8.1.2 (in these criteria, a_n should be replaced by $|a_n|$).

Example 3. The series $1 + \frac{1}{2^2} - \frac{1}{3^2} - \frac{1}{4^2} + \frac{1}{5^2} + \frac{1}{6^2} - \cdots$ is absolutely convergent, since the series with the absolute values of its terms, $\sum\limits_{n=1}^{\infty} \frac{1}{n^2}$, is convergent (see the second series in Example 2 of Subsection M8.1.2 for $\alpha = 2$).

2. *Conditionally convergent series.* A convergent series $\sum\limits_{n=1}^{\infty} a_n$ is called *conditionally convergent* if the series $\sum\limits_{n=1}^{\infty} |a_n|$ is divergent.

Example 4. The series $1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + \cdots$ is conditionally convergent, since it is convergent (by the Leibniz criterion), but the series with absolute values of its terms is divergent (it is a harmonic series; see Example 2 in Subsection M8.1.2).

Any rearrangement of the terms of an absolutely convergent series (in particular, a convergent series with nonnegative terms) neither violates its absolute convergence nor changes its sum. Conditionally convergent series do not possess this property: the terms of a conditionally convergent series can be rearranged in such order that the sum of the new series becomes equal to any given value; its terms can also be rearranged so as to result in a divergent series.

M8.1.4. Multiplication of Series. Some Inequalities

► **Multiplication of series. Cauchy, Mertens, and Abel theorems.** A product of two infinite series $\sum\limits_{n=0}^{\infty} a_n$ and $\sum\limits_{n=0}^{\infty} b_n$ is understood as a series whose terms have the form $a_n b_m$ (n, $m = 0, 1, \ldots$). The products $a_n b_m$ can be ordered to form a series in many different ways. The following theorems allow us to decide whether it is possible to multiply series.

CAUCHY THEOREM. *Suppose that the series* $\sum\limits_{n=0}^{\infty} a_n$ *and* $\sum\limits_{n=0}^{\infty} b_n$ *are absolutely convergent and their sums are equal to* A *and* B*, respectively. Then any product of these series is an absolutely convergent series and its sum is equal to* AB*. The following Cauchy multiplication formula holds*:

$$\left(\sum_{n=0}^{\infty} a_n\right)\left(\sum_{n=0}^{\infty} b_n\right) = \sum_{n=0}^{\infty}\left(\sum_{m=0}^{n} a_m b_{n-m}\right). \qquad \text{(M8.1.4.1)}$$

MERTENS THEOREM. *The Cauchy multiplication formula (M8.1.4.1) is also valid if one of the series,* $\sum\limits_{n=0}^{\infty} a_n$ *or* $\sum\limits_{n=0}^{\infty} b_n$*, is absolutely convergent and the other is (conditionally) convergent. In this case, the product is a convergent series, possibly, not absolutely convergent.*

ABEL THEOREM. *Consider two convergent series with sums* A *and* B*. Suppose that the product of these series in the form of Cauchy (M8.1.4.1) is a convergent series with sum* C*. Then* $C = AB$*.*

► **Inequalities.**

1. *Generalized triangle inequality*:

$$\left|\sum_{n=1}^{\infty} a_n\right| \le \sum_{n=1}^{\infty} |a_n|.$$

2. *Cauchy inequality* (*Cauchy–Schwarz–Bunyakovsky inequality*):

$$\left(\sum_{n=1}^{\infty} a_n b_n\right)^2 \le \left(\sum_{n=1}^{\infty} a_n^2\right)\left(\sum_{n=1}^{\infty} b_n^2\right).$$

3. *Minkowski inequality*:

$$\left(\sum_{n=1}^{\infty} |a_n + b_n|^p\right)^{\frac{1}{p}} \le \left(\sum_{n=1}^{\infty} |a_n|^p\right)^{\frac{1}{p}} + \left(\sum_{n=1}^{\infty} |b_n|^p\right)^{\frac{1}{p}}, \qquad p \ge 1.$$

In all these inequalities it is assumed that the series on the right-hand sides are convergent.

M8.2. Function Series

M8.2.1. Pointwise and Uniform Convergence of Function Series

► **Convergence of a function series at a point. Convergence domain.** A *function series* is a series of the form

$$u_1(x) + u_2(x) + \cdots + u_n(x) + \cdots = \sum_{n=1}^{\infty} u_n(x),$$

where $u_n(x)$ are functions defined on a set $X \subset \mathbb{R}$. The series $\sum\limits_{n=1}^{\infty} u_n(x)$ is called *convergent at a point* $x_0 \in X$ if the numerical series $\sum\limits_{n=1}^{\infty} u_n(x_0)$ is convergent. The set of all $x \in X$ for which the function series is convergent is called its *convergence domain*. The sum of the series is a function of x defined on its convergence domain.

In order to find the convergence domain for a function series, one can use the convergence criteria for numerical series described in Subsections M8.1.2 and M8.1.3 (with the variable x regarded as a parameter).

A series $\sum\limits_{n=1}^{\infty} u_n(x)$ is called *absolutely convergent on a set* X if the series $\sum\limits_{n=1}^{\infty} |u_n(x)|$ is convergent on this set.

Example. The function series

$$1 + x + x^2 + x^3 + \cdots$$

is convergent for $-1 < x < 1$ (see Example 1 in Subsection M8.1.1). Its sum is defined on this interval, $S = \dfrac{1}{1-x}$.

The series $\sum\limits_{k=n+1}^{\infty} u_k(x)$ is called the *remainder of a function series* $\sum\limits_{n=1}^{\infty} u_n(x)$. For a series convergent on a set X, the relation $S(x) = s_n(x) + r_n(x)$, where $s_n(x)$ is the partial sum of the series and $r_n(x)$ is the sum of its remainder, implies that $\lim\limits_{n\to\infty} r_n(x) = 0$ for $x \in X$.

► **Uniformly convergent series. Condition of uniform convergence.** A function series is called *uniformly convergent* on a set X if for any $\varepsilon > 0$ there exists an N (dependent on ε but not on x) such that for all $n > N$, the inequality

$$\left|\sum_{k=n+1}^{\infty} u_k(x)\right| < \varepsilon$$

holds for all $x \in X$.

A *necessary and sufficient condition of uniform convergence of a series.* A series $\sum\limits_{n=1}^{\infty} u_n(x)$ is uniformly convergent on a set X if and only if for any $\varepsilon > 0$ there exists an N (independent of x) such that for all $n > N$ and all $m = 1, 2, \ldots$, the inequality

$$\left|\sum_{k=n+1}^{n+m} u_k(x)\right| < \varepsilon$$

holds for all $x \in X$.

M8.2.2. Basic Criteria of Uniform Convergence. Properties of Uniformly Convergent Series

► **Criteria of uniform convergence of series.**

1. *Weierstrass criterion of uniform convergence.* A function series $\sum\limits_{n=1}^{\infty} u_n(x)$ is uniformly convergent on a set $X \subset \mathbb{R}$ if there is a convergent number series $\sum\limits_{n=1}^{\infty} a_n$ with

nonnegative terms such that $|u_n(x)| \le a_n$ for all sufficiently large n and all $x \in X$. The series $\sum\limits_{n=1}^{\infty} a_n$ is called a *majorant series* for $\sum\limits_{n=1}^{\infty} u_n(x)$.

Example. The series $\sum\limits_{n=1}^{\infty}(-1)^n \dfrac{\sin nx}{n^2}$ is uniformly convergent for $-\infty < x < \infty$, since $\left|(-1)^n \dfrac{\sin nx}{n^2}\right| \le \dfrac{1}{n^2}$, and the numerical series $\sum\limits_{n=1}^{\infty} \dfrac{1}{n^2}$ is convergent (see the second series in Example 2 in Subsection M8.1.2).

2. *Abel criterion of uniform convergence of function series.* Consider a function series

$$\sum_{n=1}^{\infty} u_n(x)v_n(x) = u_1(x)v_1(x) + u_2(x)v_2(x) + \cdots + u_n(x)v_n(x) + \cdots, \qquad \text{(M8.2.2.1)}$$

where $u_n(x)$ and $v_n(x)$ are sequences of functions of the real variable $x \in [a, b]$.

Series (M8.2.2.1) is uniformly convergent on the interval $[a, b]$ if the series

$$\sum_{n=1}^{\infty} v_n(x) = v_1(x) + v_2(x) + \cdots + v_n(x) + \cdots \qquad \text{(M8.2.2.2)}$$

is uniformly convergent on $[a, b]$ and the functions $u_n(x)$ form a monotone sequence for each x and are uniformly bounded (i.e., $|u_n(x)| \le K$ with a constant K independent of n, x).

3. *Dirichlet criterion of uniform convergence of function series.* Series (M8.2.2.1) is uniformly convergent on the interval $[a, b]$ if the partial sums of the series (M8.2.2.2) are uniformly bounded, i.e.,

$$\left|\sum_{k=1}^{n} v_k(x)\right| \le M = \text{const} \qquad (x \in [a, b], \quad n = 1,\ 2,\ \dots),$$

and the functions $u_n(x)$ form a monotone sequence (for each x) that uniformly converges to zero on $[a, b]$ as $n \to \infty$.

▶ **Properties of uniformly convergent series.** Let $\sum\limits_{n=1}^{\infty} u_n(x)$ be a function series that is uniformly convergent on a segment $[a, b]$, and let $S(x)$ be its sum. Then the following statements hold.

THEOREM 1. *If all terms $u_n(x)$ of the series are continuous at a point $x_0 \in [a, b]$, then the sum $S(x)$ is continuous at that point.*

THEOREM 2. *If the terms $u_n(x)$ are continuous on $[a, b]$, then the series admits term-by-term integration:*

$$\int_a^b S(x)\,dx = \int_a^b \left(\sum_{n=1}^{\infty} u_n(x)\right) dx = \sum_{n=1}^{\infty} \int_a^b u_n(x)\,dx.$$

Remark. The condition of continuity of the functions $u_n(x)$ on $[a, b]$ can be replaced by a weaker condition of their integrability on $[a, b]$.

THEOREM 3. *If all terms of the series have continuous derivatives and the function series $\sum\limits_{n=1}^{\infty} u_n'(x)$ is uniformly convergent on $[a, b]$, then the sum $S(x)$ is continuously differentiable on $[a, b]$ and*

$$S'(x) = \left(\sum_{n=1}^{\infty} u_n(x)\right)' = \sum_{n=1}^{\infty} u_n'(x)$$

(i.e., the series admits term-by-term differentiation).

M8.3. Power Series

M8.3.1. Radius of Convergence of Power Series. Properties of Power Series

► **Abel theorem. Convergence radius of a power series.** A *power series* is a function series of the form

$$\sum_{n=0}^{\infty} a_n x^n = a_0 + a_1 x + a_2 x^2 + a_3 x^3 + \cdots \qquad \text{(M8.3.1.1)}$$

(the constants $a_0, a_1, \dots$ are called the *coefficients* of the power series), and also a series of a more general form

$$\sum_{n=0}^{\infty} a_n (x-x_0)^n = a_0 + a_1(x-x_0) + a_2(x-x_0)^2 + a_3(x-x_0)^3 + \cdots ,$$

where x_0 is a fixed point. Below, we consider power series of the first form, since the second series can be transformed into the first by the replacement $\bar{x} = x - x_0$.

ABEL THEOREM. *A power series $\sum_{n=0}^{\infty} a_n x^n$ that is convergent for some $x = x_1$ is absolutely convergent for all x such that $|x| < |x_1|$. A power series that is divergent for some $x = x_2$ is divergent for all x such that $|x| > |x_2|$.*

Remark. There exist series convergent for all x, for instance, $\sum_{n=1}^{\infty} \frac{x^n}{n!}$. There are series convergent only for $x = 0$, for instance, $\sum_{n=1}^{\infty} n!\, x^n$.

For a given power series (M8.3.1.1), let R be the least upper bound of all $|x|$ such that the series (M8.3.1.1) is convergent at point x. Thus, by the Abel theorem, the series is (absolutely) convergent for all $|x| < R$, and the series is divergent for all $|x| > R$. The constant R is called the *radius of convergence* of the power series, and the interval $(-R, R)$ is called its *interval of convergence*. The problem of convergence of a power series at the endpoints of its convergence interval has to be studied separately in each specific case. If a series is convergent only for $x = 0$, the convergence interval degenerates into a point (and $R = 0$); if a series is convergent for all x, then, obviously, $R = \infty$.

► **Formulas for the radius of convergence of power series.**

1°. The radius of convergence of a power series (M8.3.1.1) with finitely many zero terms can be calculated by the formulas

$$R = \lim_{n\to\infty} \left| \frac{a_n}{a_{n+1}} \right| \quad \text{(obtained from the d'Alembert criterion for numerical series),}$$

$$R = \lim_{n\to\infty} \frac{1}{\sqrt[n]{|a_n|}} \quad \text{(obtained from the Cauchy criterion for numerical series).}$$

Example 1. For the power series $\sum_{n=1}^{\infty} \frac{3^n}{n} x^n$, using the first formula for the radius of convergence, we get

$$R = \lim_{n\to\infty} \left| \frac{a_n}{a_{n+1}} \right| = \lim_{n\to\infty} \left| \frac{n+1}{3n} \right| = \frac{1}{3}.$$

Therefore, the series is absolutely convergent on the interval $-\frac{1}{3} < x < \frac{1}{3}$ and is divergent outside that interval. At the left endpoint of the interval, for $x = -\frac{1}{3}$, we have the conditionally convergent series $\sum_{n=1}^{\infty} \frac{(-1)^n}{n}$, and at the right endpoint, for $x = \frac{1}{3}$, we have the divergent numerical series $\sum\limits_{n=1}^{\infty} \frac{1}{n}$. Thus, the series under consideration is convergent on the semi-open interval $\left[-\frac{1}{3}, \frac{1}{3}\right)$.

If the number of zero coefficients in a power series is infinite, the above formulas for R are inapplicable. In such cases, one can directly apply the d'Alembert or Cauchy criteria to the series.

Example 2. For the power series $\displaystyle\sum_{n=1}^{\infty} \frac{4^n}{n} x^{2n}$, the d'Alembert criterion gives

$$\lim_{n\to\infty} \left| \frac{a_{n+1} x^{2(n+1)}}{a_n x^{2n}} \right| = \lim_{n\to\infty} \left| \frac{4nx^2}{n+1} \right| = 4x^2.$$

Then the given series is absolutely convergent if $4x^2 < 1$, or on the interval $-\frac{1}{2} < x < \frac{1}{2}$, and hence $R = \frac{1}{2}$. (It is easily seen that the original series diverges at both endpoints of the interval of convergence.)

2°. Suppose that a power series (M8.3.1.1) is convergent at a boundary point of its convergence interval, say, for $x = R$. Then its sum is left-continuous at that point,

$$\lim_{x\to R-0} \sum_{n=0}^{\infty} a_n x^n = \sum_{n=0}^{\infty} a_n R^n.$$

Example 3. Having the expansion

$$\ln(1+x) = x - \frac{x^2}{2} + \frac{x^3}{3} - \cdots + (-1)^{n+1} \frac{x^n}{n} + \cdots \qquad (R = 1)$$

in the domain $-1 < x < 1$ and knowing that the series

$$1 - \frac{1}{2} + \frac{1}{3} - \cdots + (-1)^{n+1} \frac{1}{n} + \cdots$$

is convergent (by the Leibniz criterion for series with terms of alternating sign), we conclude that the sum of the last series is equal to ln 2.

► **Properties of power series.** On any closed segment belonging to the (open) convergence interval of a power series, the series is uniformly convergent. Therefore, on any such segment, the series has all the properties of uniformly convergent series described in Subsection M8.2.2. Therefore, the following statements hold:

1. A power series (M8.3.1.1) admits term-by-term integration on any segment $[0, x]$ for $|x| < R$,

$$\int_0^x \left(\sum_{n=0}^{\infty} a_n x^n \right) dx = \sum_{n=0}^{\infty} \frac{a_n}{n+1} x^{n+1}$$
$$= a_0 x + \frac{a_1}{2} x^2 + \frac{a_2}{3} x^3 + \cdots + \frac{a_n}{n+1} x^{n+1} + \cdots .$$

Remark 1. The value of x in this formula may coincide with an endpoint of the convergence interval ($x = -R$ and/or $x = R$), provided that series (M8.3.1.1) is convergent at that point.

Remark 2. The convergence radii of the original series and the series obtained by its term-by-term integration on the segment $[0, x]$ coincide.

2. Inside the convergence interval (for $|x| < R$), the series admits term-by-term differentiation of any order, in particular,

$$\frac{d}{dx} \left(\sum_{n=0}^{\infty} a_n x^n \right) = \sum_{n=1}^{\infty} n a_n x^{n-1}$$
$$= a_1 + 2a_2 x + 3a_3 x^2 + \cdots + n a_n x^{n-1} + \cdots .$$

Remark 1. The sum of a power series is a function that has derivatives of any order inside the interval of convergence.

Remark 2. The convergence radii of the original series and the series obtained by its term-by-term differentiation coincide.

M8.3.2. Taylor and Maclaurin Power Series

► **Basic definitions.** Let $f(x)$ be an infinitely differentiable function at a point x_0. The *Taylor series* for this function is the power series

$$\sum_{n=0}^{\infty} \frac{1}{n!} f^{(n)}(x_0)(x-x_0)^n = f(x_0) + f'(x_0)(x-x_0) + \frac{1}{2} f''(x_0)(x-x_0)^2 + \cdots,$$

where $0! = 1$ and $f^{(0)}(x_0) = f(x_0)$.

A special case of the Taylor series (for $x_0 = 0$) is the *Maclaurin series*:

$$\sum_{n=0}^{\infty} \frac{1}{n!} f^{(n)}(0)x^n = f(0) + f'(0)x + \frac{1}{2} f''(0)x^2 + \cdots.$$

A formal Taylor series (Maclaurin series) for a function $f(x)$ may be:

1) divergent for $x \neq x_0$,
2) convergent in a neighborhood of x_0 to a function different from $f(x)$,
3) convergent in a neighborhood of x_0 to the function $f(x)$.

In the last case, one says that $f(x)$ is *expandable in a Taylor series* in the said neighborhood, and one writes

$$f(x) = \sum_{n=0}^{\infty} \frac{1}{n!} f^{(n)}(x_0)(x-x_0)^n.$$

► **Conditions of expansion in Taylor series.** A *necessary and sufficient condition for a function $f(x)$ to be represented by its Taylor series* in a neighborhood of a point x_0 is that the remainder term in the Taylor formula* should tend to zero as $n \to \infty$ in this neighborhood of x_0.

In order that $f(x)$ could be represented by its Taylor series in a neighborhood of x_0, it suffices that all its derivatives in that neighborhood be bounded by the same constant, $|f^{(n)}(x)| \le M$ for all n.

Uniqueness of the Taylor series expansion. If a function $f(x)$ is representable by the sum of a power series, the coefficients of this series are determined uniquely (since this series is the Taylor series of $f(x)$ and its coefficients have the form $\dfrac{f^{(n)}(x_0)}{n!}$, where $n = 0, 1, 2, \ldots$). Therefore, in problems of representing a function by a power series, the answer does not depend on the method adopted for this purpose.

► **Representation of some functions by the Maclaurin series.** The following representations of elementary functions by Maclaurin series are often used in applications:

$$e^x = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \cdots + \frac{x^n}{n!} + \cdots;$$

$$\sin x = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \cdots + (-1)^{n-1} \frac{x^{2n-1}}{(2n-1)!} + \cdots;$$

---

* Different representations of the remainder in the Taylor formula are given in Subsection M6.2.4.

$$\cos x = 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \cdots + (-1)^n \frac{x^{2n}}{(2n)!} + \cdots ;$$
$$\sinh x = x + \frac{x^3}{3!} + \frac{x^5}{5!} + \cdots + \frac{x^{2n-1}}{(2n-1)!} + \cdots ;$$
$$\cosh x = 1 + \frac{x^2}{2!} + \frac{x^4}{4!} + \cdots + \frac{x^{2n}}{(2n)!} + \cdots ;$$
$$(1+x)^\alpha = 1 + \alpha x + \frac{\alpha(\alpha-1)}{2!}x^2 + \cdots + \frac{\alpha(\alpha-1)\ldots(\alpha-n+1)}{n!}x^n + \cdots ;$$
$$\ln(1+x) = x - \frac{x^2}{2} + \frac{x^3}{3} - \cdots + (-1)^{n+1}\frac{x^n}{n} + \cdots ;$$
$$\arctan x = x - \frac{x^3}{3} + \frac{x^5}{5} - \cdots + (-1)^{n+1}\frac{x^{2n-1}}{2n-1} + \cdots .$$

The first five series are convergent for $-\infty < x < \infty$ ($R = \infty$), and the other series have unit radius of convergence, $R = 1$.

M8.3.3. Operations with Power Series. Summation Formulas for Power Series

► **Addition, subtraction, multiplication, and division of power series.**

1. *Addition and subtraction of power series*. Two series $\sum_{n=0}^{\infty} a_n x^n$ and $\sum_{n=0}^{\infty} b_n x^n$ with convergence radii R_a and R_b, respectively, admit term-by-term addition and subtraction on the intersection of their convergence intervals:

$$\sum_{n=0}^{\infty} a_n x^n \pm \sum_{n=0}^{\infty} b_n x^n = \sum_{n=0}^{\infty} c_n x^n, \qquad c_n = a_n \pm b_n.$$

The radius of convergence of the resulting series satisfies the inequality $R_c \ge \min[R_a, R_b]$.

2. *Multiplication of power series*. Two series $\sum_{n=0}^{\infty} a_n x^n$ and $\sum_{n=0}^{\infty} b_n x^n$, with the respective convergence radii R_a and R_b, can be multiplied on the intersection of their convergence intervals, and their product has the form

$$\biggl(\sum_{n=0}^{\infty} a_n x^n\biggr)\biggl(\sum_{n=0}^{\infty} b_n x^n\biggr) = \sum_{n=0}^{\infty} c_n x^n, \qquad c_n = \sum_{k=0}^{n} a_k b_{n-k}.$$

The convergence radius of the product satisfies the inequality $R_c \ge \min[R_a, R_b]$.

3. *Division of power series*. The ratio of two power series $\sum_{n=0}^{\infty} a_n x^n$ and $\sum_{n=0}^{\infty} b_n x^n$, $b_0 \neq 0$, with convergence radii R_a and R_b can be represented as a power series

$$\frac{\sum_{n=0}^{\infty} a_n x^n}{\sum_{n=0}^{\infty} b_n x^n} = c_0 + c_1 x + c_2 x^2 + \cdots = \sum_{n=0}^{\infty} c_n x^n, \qquad \text{(M8.3.3.1)}$$

whose coefficients can be found, by the method of indefinite coefficients, from the relation

$$(a_0 + a_1x + a_2x^2 + \cdots) = (b_0 + b_1x + b_2x^2 + \cdots)(c_0 + c_1x + c_2x^2 + \cdots).$$

Thus, for the unknown c_n, we obtain a triangular system of linear algebraic equations

$$a_n = \sum_{k=0}^{n} b_k c_{n-k}, \qquad n = 0,\ 1,\ \dots\ ,$$

which is solved consecutively, starting from the first equation:

$$c_0 = \frac{a_0}{b_0}, \quad c_1 = \frac{a_1b_0 - a_0b_1}{b_0^2}, \quad c_n = \frac{a_n}{b_0} - \frac{1}{b_0}\sum_{k=1}^{n} b_k c_{n-k}, \quad n = 2,\ 3,\ \dots$$

The convergence radius of the series (M8.3.3.1) is determined by the formula

$$R_1 = \min\Bigl[R_a, \frac{\rho}{M+1}\Bigr],$$

where ρ is any constant such that $0 < \rho < R_b$; ρ can be chosen arbitrarily close to R_b; and M is the least upper bound of the quantities $|b_m/b_0|\rho^m$ ($m = 1,\ 2,\ \dots$), so that $|b_m/b_0|\rho^m \le M$ for all m.

► **Composition of functions representable by power series.** Consider a power series

$$z = f(y) = a_0 + a_1y + a_2y^2 + \cdots = \sum_{n=0}^{\infty} a_n y^n \tag{M8.3.3.2}$$

with convergence radius R. Let the variable y be a function of x that can be represented by a power series

$$y = \varphi(x) = b_0 + b_1x + a_2x^2 + \cdots = \sum_{n=0}^{\infty} b_n x^n \tag{M8.3.3.3}$$

with convergence radius r. It is required to represent z as a power series of x and find the convergence radius of this series.

Formal substitution of (M8.3.3.3) into (M8.3.3.2) yields

$$z = f\bigl(\varphi(x)\bigr) = \sum_{n=0}^{\infty} a_n\Bigl(\sum_{k=0}^{\infty} b_k x^k\Bigr)^n = A_0 + A_1x + A_2x^2 + \cdots = \sum_{n=0}^{\infty} A_n x^n, \tag{M8.3.3.4}$$

where

$$\begin{aligned}
A_0 &= a_0 + a_1b_0 + a_2b_0^2 + \cdots\ ,\\
A_1 &= a_1b_1 + 2a_2b_0b_1 + 3a_3b_0^2b_1 + \cdots\ ,\\
A_2 &= a_1b_2 + a_2(b_1^2 + 2b_0b_2) + 3a_3(b_0b_1^2 + b_0^2b_2) + \cdots\ ,\\
&\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots .
\end{aligned}$$

THEOREM ON CONVERGENCE OF SERIES (M8.3.3.4).

(i) If series (M8.3.3.2) is convergent for all y (i.e., $R = \infty$), then the convergence radius of series (M8.3.3.4) coincides with the convergence radius r of series (M8.3.3.3).

(ii) If $0 \le |b_0| < R$, then series (M8.3.3.4) is convergent on the interval $(-R_1, R_1)$, where

$$R_1 = \frac{(R - |b_0|)\rho}{M + R - |b_0|},$$

and ρ is an arbitrary constant such that $0 < \rho < r$; ρ can be chosen arbitrarily close to r; and M is the least upper bound of the quantities $|b_m|\rho^m$ ($m = 1,\ 2,\ \dots$), so that $|b_m|\rho^m \le M$ for all m.

(iii) If $|b_0| > R$, then series (M8.3.3.4) is divergent.

Remark. Case (i) is realized if, for instance, (M8.3.3.2) has finitely many terms.

▶ **Simplest summation formulas for power series.** Suppose that the sum of a power series is known,

$$\sum_{k=0}^{\infty} a_k x^k = S(x). \tag{M8.3.3.6}$$

Then, using term-by-term integration (on the convergence interval), one can find the following sums:

$$\begin{aligned}
&\sum_{k=0}^{\infty} a_k k^m x^k = \left(x\frac{d}{dx}\right)^m S(x);\\
&\sum_{k=0}^{\infty} a_k (nk+m) x^{nk+m-1} = \frac{d}{dx}\bigl[x^m S(x^n)\bigr];\\
&\sum_{k=0}^{\infty} \frac{a_k}{nk+m} x^{nk+m} = \int_0^x x^{m-1} S(x^n)\,dx, \qquad n>0,\ \ m>0;\\
&\sum_{k=0}^{\infty} a_k \frac{nk+s}{nk+m} x^{nk+s} = x\frac{d}{dx}\left[x^{s-m}\int_0^x x^{m-1} S(x^n)\,dx\right], \qquad n>0,\ \ m>0;\\
&\sum_{k=0}^{\infty} a_k \frac{nk+m}{nk+s} x^{nk+s} = \int_0^x x^{s-m}\frac{d}{dx}\Bigl[x^m S(x^n)\Bigr]\,dx, \qquad n>0,\ \ s>0.
\end{aligned} \tag{M8.3.3.7}$$

Example 2. Let us find the sum of the series $\sum\limits_{k=0}^{\infty} kx^{k-1}$.

We start with the well-known formula for the sum of an infinite geometrical progression:

$$\sum_{k=0}^{\infty} x^k = \frac{1}{1-x} \qquad (|x|<1).$$

This series is a special case of (M8.3.3.6) with $a_k = 1$, $S(x) = 1/(1-x)$. The series $\sum\limits_{k=0}^{\infty} kx^{k-1}$ can be obtained from the left-hand side of the second formula in (M8.3.3.7) for $m = 0$ and $n = 1$. Substituting $S(x) = 1/(1-x)$ into the right-hand side of that formula, we get

$$\sum_{k=0}^{\infty} kx^{k-1} = \frac{d}{dx}\frac{1}{1-x} = \frac{1}{(1-x)^2} \qquad (|x|<1).$$

M8.4. Fourier Series

M8.4.1. Representation of 2π-Periodic Functions by Fourier Series. Main Results

▶ **Dirichlet theorem on representation of a function by Fourier series.** A function $f(x)$ is said to satisfy the *Dirichlet conditions* on an interval (a, b) if:

1) this interval can be divided into finitely many intervals on which $f(x)$ is monotone and continuous;

2) at any discontinuity point x_0 of the function, there exist finite one-sided limits $f(x_0+0)$ and $f(x_0-0)$.

DIRICHLET THEOREM. *Any 2π-periodic function that satisfies the Dirichlet conditions on the interval $(-\pi,\pi)$ can be represented by its Fourier series*

$$f(x)=\frac{a_0}{2}+\sum_{n=1}^{\infty}\bigl(a_n\cos nx+b_n\sin nx\bigr) \qquad \text{(M8.4.1.1)}$$

whose coefficients are defined by the Euler–Fourier formulas

$$\begin{aligned} a_n&=\frac{1}{\pi}\int_{-\pi}^{\pi}f(x)\cos nx\,dx, && n=0,\ 1,\ 2,\dots,\\ b_n&=\frac{1}{\pi}\int_{-\pi}^{\pi}f(x)\sin nx\,dx, && n=1,\ 2,\ 3,\dots \end{aligned} \qquad \text{(M8.4.1.2)}$$

At the points of continuity of $f(x)$, the Fourier series converges to $f(x)$, and at any discontinuity point x_0, the series converges to $\frac{1}{2}[f(x_0+0)+f(x_0-0)]$.

The coefficients a_n and b_n of the series (M8.4.1.1) are called the *Fourier coefficients*.

Remark. Instead of the integration limits $-\pi$ and π in (M8.4.1.2), one can take c and $c+2\pi$, where c is an arbitrary constant.

▶ **Lipschitz and Dirichlet–Jordan convergence criteria for Fourier series.** LIPSCHITZ CRITERION. *Suppose that $f(x)$ is continuous at a point x_0 and for sufficiently small $\varepsilon>0$ satisfies the inequality $|f(x_0\pm\varepsilon)-f(x_0)|\le L\varepsilon^{\sigma}$, where L and σ are constants, $0<\sigma\le 1$. Then the representation (M8.4.1.1)–(M8.4.1.2) holds at $x=x_0$.*

In particular, the conditions of the Lipschitz criterion hold for continuous piecewise differentiable functions.

Remark. The Fourier series of a continuous periodic function with no additional conditions (for instance, of its regularity) may happen to be divergent at infinitely many (even uncountably many) points.

DIRICHLET–JORDAN CRITERION. *Suppose that $f(x)$ is a function of bounded variation on some interval $(x_0-h,x_0+h)\in(-\pi,\pi)$ (i.e., $f(x)$ can be represented as a difference of two monotonically increasing functions). Then the Fourier series (M8.4.1.1)–(M8.4.1.2) of the function $f(x)$ at the point x_0 converges to the value $\frac{1}{2}[f(x_0+0)+f(x_0-0)]$.*

▶ **Asymptotic properties of Fourier coefficients.**

1°. Fourier coefficients of an absolutely integrable function tend to zero as n goes to infinity: $a_n\to 0$ and $b_n\to 0$ as $n\to\infty$.

2°. Fourier coefficients of a continuous 2π-periodic function have the following limit properties:

$$\lim_{n\to\infty}(na_n)=0,\qquad \lim_{n\to\infty}(nb_n)=0,$$

i.e., $a_n=o(1/n)$ and $b_n=o(1/n)$.

3°. If a continuous periodic function is continuously differentiable up to the order $m-1$ inclusively, then its Fourier coefficients have the following limit properties:

$$\lim_{n\to\infty}(n^m a_n)=0,\qquad \lim_{n\to\infty}(n^m b_n)=0,$$

i.e., $a_n=o\bigl(n^{-m}\bigr)$ and $b_n=o\bigl(n^{-m}\bigr)$.

M8.4.2. Fourier Expansions of Periodic, Nonperiodic, Even, and Odd Functions

► **Expansion of 2l-periodic and nonperiodic functions in Fourier series.**

1°. The case of $2l$-periodic functions can be easily reduced to that of 2π-periodic functions by changing the variable x to $z = \dfrac{\pi x}{l}$. In this way, all the results described above for 2π-periodic functions can be easily extended to $2l$-periodic functions.

The Fourier expansion of a $2l$-periodic function $f(x)$ has the form

$$f(x) = \frac{a_0}{2} + \sum_{n=1}^{\infty} \Bigl(a_n \cos\frac{n\pi x}{l} + b_n \sin\frac{n\pi x}{l}\Bigr), \qquad \text{(M8.4.2.1)}$$

where

$$a_n = \frac{1}{l}\int_{-l}^{l} f(x)\cos\frac{n\pi x}{l}\,dx, \qquad b_n = \frac{1}{l}\int_{-l}^{l} f(x)\sin\frac{n\pi x}{l}\,dx. \qquad \text{(M8.4.2.2)}$$

2°. A nonperiodic (aperiodic) function $f(x)$ defined on the interval $(-l, l)$ can also be represented by a Fourier series (M8.4.2.1)–(M8.4.2.2); however, outside that interval, the sum of that series $S(x)$ may differ from $f(x)$*.

► **Fourier expansion of even and odd functions.**

1°. Let $f(x)$ be an even function, i.e., $f(-x) = f(x)$. Then the Fourier expansion of $f(x)$ on the interval $(-l, l)$ has the form of the *cosine Fourier series*:

$$f(x) = \frac{a_0}{2} + \sum_{n=1}^{\infty} a_n \cos\frac{n\pi x}{l},$$

where the Fourier coefficients have the form

$$a_n = \frac{2}{l}\int_0^l f(x)\cos\frac{n\pi x}{l}\,dx \qquad (b_n = 0).$$

2°. Let $f(x)$ be an odd function, i.e., $f(-x) = -f(x)$. Then the Fourier expansion of $f(x)$ on the interval $(-l, l)$ has the form of the *sine Fourier series*:

$$f(x) = \sum_{n=1}^{\infty} b_n \sin\frac{n\pi x}{l},$$

where the Fourier coefficients have the form

$$b_n = \frac{2}{l}\int_0^l f(x)\sin\frac{n\pi x}{l}\,dx \qquad (a_n = 0).$$

---

* The sum $S(x)$ is a $2l$-periodic function defined for all x, but $f(x)$ may happen to be nonperiodic or even undefined outside the interval $(-l, l)$.

Example. Let us find the Fourier expansion of the function $f(x) = x$ on the interval $(-\pi, \pi)$.

Taking $l = \pi$ and $f(x) = x$ in the formula for the Fourier coefficients and integrating by parts, we obtain

$$b_n = \frac{2}{\pi}\int_0^\pi x\sin(nx)\,dx = \frac{2}{\pi}\left(-\frac{1}{n}x\cos(nx)\Big|_0^\pi + \frac{1}{n}\int_0^\pi \cos(nx)\,dx\right) = -\frac{2}{n}\cos(n\pi) = (-1)^{n+1}\frac{2}{n}.$$

Therefore, the Fourier expansion of $f(x) = x$ has the form

$$f(x) = 2\sum_{n=1}^{\infty}(-1)^{n+1}\frac{\sin(nx)}{n} \qquad (-\pi < x < \pi).$$

3°. If $f(x)$ is defined on the interval $(0, l)$ and satisfies the Dirichlet conditions, it can be represented by the cosine Fourier series, as well as the sine Fourier series (with the help of the above formulas). The cosine Fourier expansion of $f(x)$ on the interval $(0, l)$ corresponds to the extension of $f(x)$ to the interval $(-l, 0)$ as an even function: $f(-x) = f(x)$. The sine Fourier expansion of $f(x)$ on $(0, l)$ corresponds to the extension of $f(x)$ to the interval $(-l, 0)$ as an odd function: $f(-x) = -f(x)$. Both series on the interval $(0, l)$ give the values of $f(x)$ at points of its continuity and the value $\frac{1}{2}[f(x_0+0) + f(x_0-0)]$ at points of its discontinuity; outside the interval $(0, l)$, these two series represent different functions.

► **Fourier series in complex form.** The complex Fourier expansion of a function $f(x)$ on an interval $(-l, l)$ has the form

$$f(x) = \sum_{n=-\infty}^{\infty} c_n e^{i\omega_n x},$$

where

$$\omega_n = \frac{n\pi}{l}, \quad c_n = \frac{1}{2l}\int_{-l}^{l} f(x)e^{-i\omega_n x}\,dx; \quad n = 0,\ \pm1,\ \pm2,\ \ldots$$

The expressions $e^{i\omega_n x}$ are called *complex harmonics*, the coefficients c_n are *complex amplitudes*, ω_n are *wave numbers* of the function $f(x)$, and the set of all wave numbers $\{\omega_n\}$ is called the *discrete spectrum* of the function.

M8.4.3. Criteria of Uniform and Mean-Square Convergence of Fourier Series

► **Criteria of uniform convergence of Fourier series.**

LIPSCHITZ CRITERION. *The Fourier series of a function $f(x)$ converges uniformly to that function on an interval $[-l, l]$ if on a wider interval $[-L, L]$ $(-L < -l < l < L)$ the following inequality holds:*

$$|f(x_1) - f(x_2)| \le K|x_1 - x_2|^\sigma \quad \text{for all} \quad x_1, x_2 \in [-L, L],$$

where K and σ are constants, $0 < \sigma \le 1$.

Corollary. The Fourier series of a continuous function $f(x)$ converges uniformly to that function on an interval $[-l, l]$ if on a wider interval the function $f(x)$ has a bounded derivative $f'(x)$.

For any continuously differentiable $2l$-periodic function $f(x)$, its Fourier series [defined by formulas (M8.4.2.1)–(M8.4.2.2)] is uniformly convergent to $f(x)$.

► Fourier series of square-integrable functions. Parseval identity.

1°. For a continuous 2π-periodic function $f(x)$, its Fourier series (M8.4.1.1)–(M8.4.1.2) converges to $f(x)$ in mean square, i.e.,

$$\int_{-\pi}^{\pi}[f(x)-f_n(x)]^2\,dx\to 0\quad\text{as}\quad n\to\infty,$$

where $f_n(x)=\frac{1}{2}a_0+\sum\limits_{k=1}^{n}(a_k\cos kx+b_k\sin kx)$ is a partial sum of the Fourier series.

2°. If $f(x)$ is integrable on the segment $[-\pi,\pi]$ and the integral $\int_{-\pi}^{\pi}f^2(x)\,dx$ exists as an improper integral with finitely many singularities, then the Fourier series (M8.4.1.1)–(M8.4.1.2) is mean-square convergent to $f(x)$.

3°. Let $f(x)\in L^2[-\pi,\pi]$ be a square-integrable function on the segment $[-\pi,\pi]$. Then its Fourier series (M8.4.1.1)–(M8.4.1.2) is mean-square convergent to $f(x)$, and the *Parseval identity* holds:

$$\frac{a_0^2}{2}+\sum_{n=1}^{\infty}(a_n^2+b_n^2)=\frac{1}{\pi}\int_{-\pi}^{\pi}f^2(x)\,dx,$$

where a_n, b_n are defined by (M8.4.1.2). Note that the functions considered in Items 1° and 2° belong to $L^2[-\pi,\pi]$.

Chapter M9

Functions of Complex Variable

M9.1. Complex Numbers

M9.1.1. Definition of a Complex Number. Arithmetic Operations with Complex Numbers

► **Definition of a complex number. Geometric interpretation.** The set of complex numbers is an extension of the set of real numbers. An expression of the form $z = x + iy$, where x and y are real numbers, is called a *complex number*, and the symbol i is called the *imaginary unit*, which possesses the property $i^2 = -1$. The numbers x and y are called, respectively, the *real* and *imaginary parts* of z and denoted by

$$x = \operatorname{Re} z \quad \text{and} \quad y = \operatorname{Im} z.$$

The complex number $x + i0$ is identified with real number x, and the number $0 + iy$ is denoted by iy and is said to be *pure imaginary*. Two complex numbers $z_1 = x_1 + iy_1$ and $z_2 = x_2 + iy_2$ are *equal* if $x_1 = x_2$ and $y_1 = y_2$.

The complex number $\bar{z} = x - iy$ is said to be *conjugate* to the number z.

A complex number $z = x + iy$ can be conveniently represented as a point (x, y) in a two-dimensional Cartesian coordinate system (see Fig. M9.1). The axes OX and OY are called the *real* and *imaginary* axis, respectively, and the plane OXY is called the *complex plane*. The notions of a complex number and a point on the complex plane are identical.

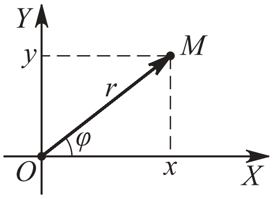

Figure M9.1. Geometric interpretation of a complex number.

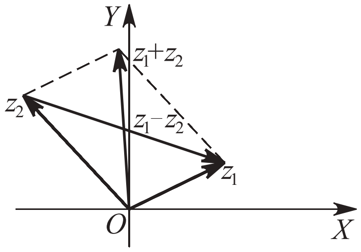

Figure M9.2. The sum and difference of complex numbers.

► **Addition, subtraction, multiplication, and division of complex numbers.** The *sum or difference* of complex numbers $z_1 = x_1 + iy_1$ and $z_2 = x_2 + iy_2$ is defined as the number

$$z_1 \pm z_2 = x_1 \pm x_2 + i(y_1 \pm y_2).$$

The *geometric meaning of the operations of addition and subtraction of complex numbers* is as follows: the sum and the difference of complex numbers z_1 and z_2 are the vectors equal to the directed diagonals of the parallelogram spanned by the vectors z_1 and z_2 (Fig. M9.2). The following inequalities hold (Fig. M9.2):

$$|z_1 + z_2| \le |z_1| + |z_2|, \quad |z_1 - z_2| \ge \big||z_1| - |z_2|\big|. \tag{M9.1.2.1}$$

Inequalities (M9.1.2.1) become equalities if and only if the arguments of the complex numbers z_1 and z_2 coincide (i.e., $\arg z_1 = \arg z_2$; see Subsection M9.1.2) or one of the numbers is zero.

The *product* z_1z_2 of complex numbers $z_1 = x_1 + iy_1$ and $z_2 = x_2 + iy_2$ is defined to be the number

$$z_1z_2 = (x_1x_2 - y_1y_2) + i(x_1y_2 + x_2y_1).$$

The product of a complex number $z = x + iy$ by its conjugate is always nonnegative:

$$z\bar{z} = x^2 + y^2.$$

If $z_2 \neq 0$, then the *quotient* of z_1 and z_2 is defined as

$$\frac{z_1}{z_2} = \frac{x_1x_2 + y_1y_2}{x_2^2 + y_2^2} + i\frac{x_2y_1 - x_1y_2}{x_2^2 + y_2^2}. \qquad \text{(M9.1.1.1)}$$

Relation (M9.1.1.1) can be obtained by multiplying the numerator and the denominator of the fraction z_1/z_2 by $\bar{z}_2$.

M9.1.2. Trigonometric Form of Complex Numbers. Powers and Radicals

► **Modulus and argument of a complex number.** There is a one-to-one correspondence between complex numbers $z = x + iy$ and points M with coordinates (x, y) on the plane with a Cartesian rectangular coordinate system OXY or with vectors $\overrightarrow{OM}$ connecting the origin O with M (Fig. M9.1). The length r of the vector $\overrightarrow{OM}$ is called the *modulus* (also *magnitude* and *absolute value*) of the number z and is denoted by $r = |z|$, and the angle φ formed by the vector $\overrightarrow{OM}$ and the positive direction of the OX-axis is called the *argument* (also *phase*) of the number z and is denoted by $\varphi = \operatorname{Arg} z$.

The modulus of a complex number is determined by the formula

$$|z| = \sqrt{x^2 + y^2}.$$

The argument $\operatorname{Arg} z$ is determined up to a multiple of 2π, $\operatorname{Arg} z = \arg z + 2k\pi$, where k is an arbitrary integer and $\arg z$ is the *principal value* of $\operatorname{Arg} z$ determined by the condition $-\pi < \arg z \leq \pi$. The principal value $\arg z$ is given by the formula

$$\arg z = \begin{cases} \arctan(y/x) & \text{for } x > 0, \\ \pi + \arctan(y/x) & \text{for } x < 0,\ y \geq 0, \\ -\pi + \arctan(y/x) & \text{for } x < 0,\ y < 0, \\ \pi/2 & \text{for } x = 0,\ y > 0, \\ -\pi/2 & \text{for } x = 0,\ y < 0. \end{cases}$$

For $z = 0$, $\operatorname{Arg} z$ is undefined.

► **Trigonometric form of complex numbers.** Since $x = r\cos\varphi$ and $y = r\sin\varphi$, it follows that the complex number can be written in the *trigonometric* (or *polar*) *form*

$$z = x + iy = r(\cos\varphi + i\sin\varphi).$$

For two complex numbers written in trigonometric form, $z_1 = r_1(\cos\varphi_1 + i\sin\varphi_1)$ and $z_2 = r_2(\cos\varphi_2 + i\sin\varphi_2)$, the following arithmetic rules are valid:

$$z_1z_2 = r_1r_2\big[\cos(\varphi_1 + \varphi_2) + i\sin(\varphi_1 + \varphi_2)\big], \quad \frac{z_1}{z_2} = \frac{r_1}{r_2}\big[\cos(\varphi_1 - \varphi_2) + i\sin(\varphi_1 - \varphi_2)\big].$$

In the latter formula, it is assumed that $z_2 \neq 0$.

► **Powers and radicals.** For any positive integer n, the nth power of z is calculated by *de Moivre's formula*

$$z^n = r^n(\cos n\varphi + i\sin n\varphi),$$

For $z \neq 0$ and positive integer n, there are exactly n distinct values of the nth root of $z = r(\cos\varphi + i\sin\varphi)$, which are determined by

$$\sqrt[n]{z} = z^{1/n} = \sqrt[n]{r}\Big(\cos\frac{\varphi + 2k\pi}{n} + i\sin\frac{\varphi + 2k\pi}{n}\Big) \quad (k = 0, 1, 2, \dots, n-1).$$

Example. Let us find all values of $\sqrt[3]{i}$.

Let us represent the complex number $z = i$ in trigonometric form. We have $r = |z| = 1$ and $\varphi = \arg z = \frac{\pi}{2}$. The distinct values of the cube root are calculated by the formula

$$\omega_k = \sqrt[3]{1}\left(\cos\frac{\frac{\pi}{2} + 2\pi k}{3} + i\sin\frac{\frac{\pi}{2} + 2\pi k}{3}\right) \quad (k = 0, 1, 2),$$

so that

$$\omega_0 = \cos\frac{\pi}{6} + i\sin\frac{\pi}{6} = \frac{\sqrt{3}}{2} + i\frac{1}{2},$$
$$\omega_1 = \cos\frac{5\pi}{6} + i\sin\frac{5\pi}{6} = -\frac{\sqrt{3}}{2} + i\frac{1}{2},$$
$$\omega_2 = \cos\frac{3\pi}{2} + i\sin\frac{3\pi}{2} = -i.$$

The roots are shown in Fig. M9.3.

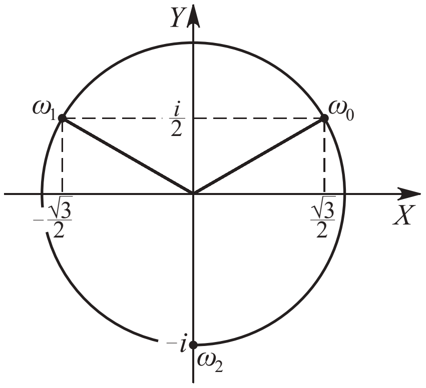

Figure M9.3. The roots of $\sqrt[3]{i}$.

M9.2. Functions of Complex Variables

M9.2.1. Basic Concepts. Differentiation of a Function of a Complex Variable

► **Some concepts and definitions.** A subset D of the complex plane such that each point of D has a neighborhood contained in D (i.e., D is open) and two arbitrary points of D can be connected by a broken line lying in D (i.e., D is connected) is called a *domain* in the complex plane. Each point of D is its *interior point*. A point that does not lie in D but whose arbitrary neighborhood contains points of D is called a *boundary point* of D. The set of all boundary points of D is called the *boundary* of D. The union of a domain D with its boundary is called a *closed domain* and denoted by $\overline{D}$. The boundary of a domain can consist of finitely many closed curves, segments, and points; the curves and cuts are assumed to be piecewise smooth.

The simplest examples of domains are neighborhoods of points on the complex plane. A *neighborhood* of a point a on the complex plane is understood as the set of points z such that $|z-a| < R$, i.e., the interior of the disk of radius $R > 0$ centered at the point a. The *extended complex plane* is obtained by augmenting the complex plane with the fictitious *point at infinity*. A *neighborhood of the point at infinity* is understood as the set of points z such that $|z| > R$ (including the point at infinity itself).

If to each point z of a domain D there corresponds a single point w (resp., a number of points w), then one says that there is a *single-valued* (resp., *multi-valued*) *function* $w = f(z)$ defined on the domain D. If we set $z = x + iy$ and $w = u + iv$, then defining a function $w = f(z)$ of the complex variable z is equivalent to defining two functions $\operatorname{Re} f = u = u(x, y)$ and $\operatorname{Im} f = v = v(x, y)$ of two real variables. If the function $w = f(z)$ is single-valued on D and the images of distinct points of D are distinct, then the mapping determined by this function is said to be *schlicht*. The notions of boundedness, limit, and continuity for single-valued functions of a complex variable do not differ from the corresponding notions for real functions of two real variables.

► **Differentiability. The Cauchy–Riemann conditions.** Let a single-valued function $w = f(z)$ be defined in a neighborhood of a point z. If there exists a limit

$$\lim_{h\to 0} \frac{f(z+h)-f(z)}{h} = f'_z(z),$$

then the function $w = f(z)$ is said to be *differentiable* at the point z and $f'_z(z)$ is called its *derivative* at the point z.

Cauchy–Riemann conditions. If the functions $u(x, y) = \operatorname{Re} f(z)$ and $v(x, y) = \operatorname{Im} f(z)$ are differentiable at a point (x, y), then the *Cauchy–Riemann conditions*

$$\frac{\partial u}{\partial x} = \frac{\partial v}{\partial y}, \qquad \frac{\partial u}{\partial y} = -\frac{\partial v}{\partial x} \tag{M9.2.1.1}$$

are necessary and sufficient for the function $w = f(z)$ to be differentiable at the point $z = x + iy$.

If the function $w = f(z)$ is differentiable, then

$$w'_z = u_x + iv_x = v_y - iu_y = u_x - iu_y = v_y + iv_x,$$

where the subscripts x and y indicate the corresponding partial derivatives.

Remark. The Cauchy–Riemann conditions are sometimes also called the d'Alembert–Euler conditions.

The rules for arithmetic operations on the derivatives and those for taking the derivative of a composite function and the inverse function (if it exists) have exactly the same form as in the case of functions of a real variable:

1. $\bigl[\alpha f_1(z) \pm \beta f_2(z)\bigr]'_z = \alpha[f_1(z)]'_z \pm \beta[f_2(z)]'_z$, where α and β are arbitrary complex constants.
2. $\bigl[f_1(z) f_2(z)\bigr]'_z = [f_1(z)]'_z f_2(z) + f_1(z)[f_2(z)]'_z$.
3. $\left[\dfrac{f_1(z)}{f_2(z)}\right]'_z = \dfrac{[f_1(z)]'_z f_2(z) - f_1(z)[f_2(z)]'_z}{f_2^2(z)} \qquad (f_2(z) \neq 0).$
4. If a function $w = f(z)$ is differentiable at a point z and a function $W = F(w)$ is differentiable at the point $w = f(z)$, then the composite function $W = F(f(z))$ is differentiable at the point z and $W'_z = [F(f(z))]'_z = F'_f(f) f'_z(z)$.

5. If a function $w = f(z)$ is differentiable at a point z and the inverse $z = g(w) \equiv f^{-1}(w)$ exists and is differentiable at the point w, then

$$[f^{-1}(w)]'_w = \frac{1}{f'_z(z)\big|_{z=f^{-1}(w)}} \qquad (f'_z(z) \neq 0).$$

► **Analyticity. The maximum modulus principle. The Liouville's theorem.** A single-valued function differentiable in some neighborhood of a point z_0 is said to be *analytic* (*regular*, *holomorphic*) at this point.

A function $w = f(z)$ is analytic at a point z_0 if and only if it can be represented by a power series

$$f(z) = \sum_{k=0}^{\infty} c_k (z - z_0)^k$$

converging in some neighborhood of z_0.

A function analytic at each point of the domain D is said to be *analytic* in D.

A function $w = f(z)$ is said to be *analytic at the point at infinity* if the function $F(z) = f(1/z)$ is analytic at the point $z = 0$.

A function $w = f(z)$ is analytic at the point at infinity if and only if this function can be represented by a power series

$$f(z) = \sum_{k=0}^{\infty} b_k z^{-k}$$

converging for sufficiently large $|z|$.

If a function $w = f(z)$ is analytic at a point z_0 and $f'_z(z_0) \neq 0$, then $f(z)$ has an analytic inverse function $z(w)$ defined in a neighborhood of the point $w_0 = f(z_0)$. If a function $w = f(z)$ is analytic at a point z_0 and the function $W = F(w)$ is analytic at the point $w_0 = f(z_0)$, then the composite function $W = F[f(z)]$ is analytic at the point z_0. If a function is analytic in a domain D and continuous in $\overline{D}$, then its value at any interior point of the domain is uniquely determined by its values on the boundary of the domain. The analyticity of a function at a point implies the existence and analyticity of its derivatives of arbitrary order at this point.

Single-valued functions, as well as single-valued branches of multi-valued functions, are analytic everywhere on the domains where they are defined. It follows from (M9.2.1.1) that the real and imaginary parts $u(x, y)$ and $v(x, y)$ of a function analytic in a domain are *harmonic* in this domain, i.e., satisfy the Laplace equation

$$\Delta f = f_{xx} + f_{yy} = 0$$

in this domain.

Remark. If $u(x, y)$ and $v(x, y)$ are two arbitrary harmonic functions, then the function $f(z) = u(x, y) + iv(x, y)$ is not necessarily analytic, since for the analyticity of $f(z)$ the functions $u(x, y)$ and $v(x, y)$ must satisfy the Cauchy–Riemann conditions.

Example 1. The function $w = z^2$ is analytic.

Indeed, since $z = x + iy$, we have $w = (x + iy)^2 = x^2 - y^2 + i2xy$, $u(x, y) = x^2 - y^2$, and $v(x, y) = 2xy$. The Cauchy–Riemann conditions

$$u_x = v_y = 2x, \quad u_y = -v_x = -2y$$

are satisfied at all points of the complex plane, so the function $w = z^2$ is analytic.

Example 2. The function $w=\bar{z}$ is not analytic.

Indeed, since $z=x+iy$, we have $w=x-iy$, $u(x,y)=x$, $v(x,y)=-y$. The Cauchy–Riemann conditions are not satisfied,

$$u_x=1\neq -1=v_y,\qquad u_y=-v_x=0,$$

so the function $w=\bar{z}$ is not analytic.

MAXIMUM MODULUS PRINCIPLE. *If a function $w=f(z)$ that is not identically constant is analytic in a domain D and continuous in $\overline{D}$, then its modulus cannot attain a maximum at an interior point of D.*

LIOUVILLE'S THEOREM. *If a function $w=f(z)$ is analytic and bounded in the entire complex plane, then it is constant.*

Remark. The Liouville theorem can be stated in the following form:
if a function $w=f(z)$ is analytic in the extended complex plane, then it is constant.

► Geometric meaning of the derivative.

Geometric meaning of the absolute value of the derivative. Suppose that a function $w=f(z)$ is analytic at a point z_0 and $f'_z(z_0)\neq 0$. Then the value $|f'_z(z_0)|$ determines the dilatation (similarity) coefficient at the point z_0 under the mapping $w=f(z)$. The value $|f'_z(z_0)|$ is called the *dilatation ratio* if $|f'_z(z_0)|>1$ and the *contraction ratio* if $|f'_z(z_0)|<1$.

Geometric meaning of the argument of the derivative. The argument of the derivative $f'_z(z_0)$ is equal to the angle by which the tangent at the point z_0 to any curve passing through z_0 should be rotated to give the tangent to the image of the curve at the point $w_0=f(z_0)$. For $\varphi=\arg f'_z(z)>0$, the rotation is counterclockwise, and for $\varphi=\arg f'_z(z)<0$, the rotation is clockwise.

► Elementary functions.

1°. Consider the *functions $w=z^n$ and $w=\sqrt[n]{z}$* for positive integer n. The function

$$w=z^n$$

is single-valued. It is schlicht in the sectors $2\pi k/n<\varphi<2\pi(k+1)/n$, $k=0,1,2,\dots$, each of which is transformed by the mapping $w=z^n$ onto the plane w with a cut on the positive real semiaxis.

The function

$$w=\sqrt[n]{z}$$

is an n-valued function for $z\neq 0$, and its value is determined by the value of the argument chosen for the point z. If a closed curve C does not surround the point $z=0$, then, as the point z goes around the entire curve C, the point $w=\sqrt[n]{z}$ for a chosen value of the root also moves along a closed curve and returns to the initial value of the argument. But if the curve C surrounds the origin, then, as the point z goes around the entire curve C in the *positive sense* (in the *counterclockwise* direction), the argument of z increases by 2π and the corresponding point $w=\sqrt[n]{z}$ does not return to the initial position. It will return there only after the point z goes n times around the entire curve C. If a domain D does not contain a closed curve surrounding the point $z=0$, then one can single out n continuous single-valued functions, each of which takes only one of the values $w=\sqrt[n]{z}$; these functions are called the *branches* of the multi-valued function $w=\sqrt[n]{z}$. One cannot single out n separate branches of the function $w=\sqrt[n]{z}$ in any neighborhood of the point $z=0$; accordingly, the point $z=0$ is called a *branch point* of this function.

2°. The *Zhukovskii function*

$$w=\frac{1}{2}\left(z+\frac{1}{z}\right)$$

is defined and single-valued for all $z \neq 0$; it is schlicht in any domain that does not simultaneously contain any points z_1 and z_2 such that $z_1 z_2 = 1$.

3°. The *exponential function* $w = e^z$ is defined by the formula

$$w = e^z = e^{x+iy} = e^x(\cos y + i \sin y).$$

The function $w = e^z$ is analytic everywhere. For the exponential function, the usual differentiation rule is preserved:

$$(e^z)'_z = e^z.$$

The basic property of the exponential function is also preserved:

$$e^{z_1} e^{z_2} = e^{z_1+z_2}.$$

For $x = 0$ and $y = \varphi$, the definition of the exponential function implies the *Euler formula* $e^{i\varphi} = \cos\varphi + i \sin\varphi$, which permits one to write any complex number with modulus r and argument φ in the *exponential form*

$$z = r(\cos\varphi + i \sin\varphi) = re^{i\varphi}.$$

The exponential function is periodic with imaginary period $2\pi i$, and the mapping $w = e^z$ is schlicht in the strip $0 \le y < 2\pi$.

4°. The *logarithm* is defined as the inverse of the exponential function: if $e^w = z$, then

$$w = \operatorname{Ln} z.$$

This function is defined for $z \neq 0$. The logarithm satisfies the following relations:

$$\operatorname{Ln} z_1 + \operatorname{Ln} z_2 = \operatorname{Ln}(z_1 z_2), \quad \operatorname{Ln} z_1 - \operatorname{Ln} z_2 = \operatorname{Ln}\frac{z_1}{z_2},$$
$$\operatorname{Ln}(z^n) = n \operatorname{Ln} z, \quad \operatorname{Ln}\sqrt[n]{z} = \frac{1}{n}\operatorname{Ln} z.$$

The exponential form of complex numbers readily shows that the logarithm is infinite-valued:

$$\operatorname{Ln} z = \ln|z| + i \operatorname{Arg} z = \ln|z| + i \arg z + 2\pi k i, \quad k = 0, \pm1, \pm2, \ldots \tag{M9.2.1.2}$$

The quantity $\ln z = \ln|z| + i \arg z$ is taken to be the principal value of this function. Just as with the function $w = \sqrt[n]{z}$, we see that if the point $z = 0$ is surrounded by a closed curve C, then the point $w = \operatorname{Ln} z$ does not return to its initial position after z goes around C in the positive sense, since the argument of w increases by $2\pi i$. Thus if a domain D does not contain a closed curve surrounding the point $z = 0$, then in D one can single out infinitely many continuous and single-valued branches of the multi-valued function $w = \operatorname{Ln} z$; the differences between the values of these branches at each point of the domain are equal to $2\pi k i$, where k is an integer. This cannot be done in an arbitrary neighborhood of the point $z = 0$, and this point is called a *branch point* of the logarithm.

5°. *Trigonometric functions* are defined in terms of the exponential function as follows:

$$\cos z = \frac{e^{iz} + e^{-iz}}{2}, \qquad \sin z = \frac{e^{iz} - e^{-iz}}{2i},$$
$$\tan z = \frac{\sin z}{\cos z} = -i\frac{e^{iz} - e^{-iz}}{e^{iz} + e^{-iz}}, \qquad \cot z = \frac{\cos z}{\sin z} = i\frac{e^{iz} + e^{-iz}}{e^{iz} - e^{-iz}}.$$

These are properties of the functions $\cos z$ and $\sin z$:

1. They are analytic for any z.
2. The usual differentiation rules are valid:

$$(\sin z)'_z = \cos z, \quad (\cos z)'_z = -\sin z.$$

3. They are periodic with real period $T = 2\pi$.
4. $\sin z$ is an odd function, and $\cos z$ is an even function.
5. In the complex plane, they are unbounded.
6. The usual trigonometric relations hold:

$$\cos^2 z + \sin^2 z = 1, \quad \cos 2z = \cos^2 z - \sin^2 z, \quad \text{etc.}$$

The function $\tan z$ is analytic everywhere except for the points

$$z_k = \frac{\pi}{2} + k\pi, \qquad k = 0,\ \pm1,\ \pm2,\ \ldots,$$

and the function $\cot z$ is analytic everywhere except for the points

$$z_k = k\pi, \qquad k = 0,\ \pm1,\ \pm2,\ \ldots$$

The functions $\tan z$ and $\cot z$ are periodic with real period $T = \pi$.

6°. *Hyperbolic functions* are defined by the formulas

$$\cosh z = \frac{e^z + e^{-z}}{2}, \qquad \sinh z = \frac{e^z - e^{-z}}{2},$$
$$\tanh z = \frac{\sinh z}{\cosh z} = \frac{e^z - e^{-z}}{e^z + e^{-z}}, \qquad \coth z = \frac{\cosh z}{\sinh z} = \frac{e^z + e^{-z}}{e^z - e^{-z}}.$$

For real values of the argument, each of these functions coincides with the corresponding real function. Hyperbolic and trigonometric functions are related by the formulas

$$\cosh z = \cos iz, \quad \sinh z = -i \sin iz, \quad \tanh z = -i \tan iz, \quad \coth z = i \cot iz.$$

7°. *Inverse trigonometric and hyperbolic functions* are expressed via the logarithm and hence are infinite-valued:

$$\operatorname{Arccos} z = -i \operatorname{Ln}(z + \sqrt{z^2 - 1}), \qquad \operatorname{Arcsin} z = -i \operatorname{Ln}(iz + \sqrt{1 - z^2}),$$
$$\operatorname{Arctan} z = -\frac{i}{2} \operatorname{Ln} \frac{1 + iz}{1 - iz}, \qquad \operatorname{Arccot} z = -\frac{i}{2} \operatorname{Ln} \frac{z + i}{z - i},$$
$$\operatorname{arccosh} z = \operatorname{Ln}(z + \sqrt{z^2 - 1}), \qquad \operatorname{arcsinh} z = \operatorname{Ln}(z + \sqrt{z^2 - 1}),$$
$$\operatorname{arctanh} z = \frac{1}{2} \operatorname{Ln} \frac{1 + z}{1 - z}, \qquad \operatorname{arccoth} z = \frac{1}{2} \operatorname{Ln} \frac{z + 1}{z - 1}.$$

The principal value of each of these functions is obtained by choosing the principal value of the corresponding logarithmic function.

8°. The *power function* $w = z^\gamma$ is defined by the relation

$$z^\gamma = e^{\gamma \operatorname{Ln} z}, \qquad \text{(M9.2.1.3)}$$

where $\gamma = \alpha + i\beta$ is an arbitrary complex number. Substituting $z = re^{i\varphi}$ into (M9.2.1.3) yields

$$z^\gamma = e^{\alpha \ln r - \beta(\varphi + 2k\pi)} e^{i\alpha(\varphi + 2k\pi) + i\beta \ln r}, \qquad k = 0,\ \pm1,\ \pm2,\ \ldots \qquad \text{(M9.2.1.4)}$$

It follows from relation (M9.2.1.4) that the function $w = z^\gamma$ has infinitely many values for $\beta \neq 0$.

9°. The *general exponential function* is defined by

$$w = \gamma^z = e^{z\,\mathrm{Ln}\,\gamma} = e^{z\ln|\gamma|}e^{zi\,\mathrm{Arg}\,\gamma}, \tag{M9.2.1.5}$$

where $\gamma = \alpha + i\beta$ is an arbitrary nonzero complex number. The function (M9.2.1.5) is a set of separate mutually independent single-valued functions that differ from one another by the factors $e^{2k\pi iz}$, $k = 0, \pm1, \pm2, \dots$

Example 3. Let us calculate the values of some elementary functions at specific points:

1. $\cos 2i = \frac{1}{2}(e^{2ii} + e^{-2ii}) = \frac{1}{2}(e^2 + e^{-2}) = \cosh 2 \approx 3.7622$.
2. $\ln(-2) = \ln 2 + i\pi$, since $|-2| = 2$ and the principal value of the argument is equal to π.
3. $\mathrm{Ln}(-2)$ is calculated by formula (M9.2.1.2):

$$\mathrm{Ln}(-2) = \ln 2 + i\pi + 2\pi ki = \ln 2 + (1 + 2k)i\pi \quad (k = 0, \pm1, \pm2, \dots).$$

4. $i^i = e^{i\,\mathrm{Ln}\,i} = e^{i(i\frac{\pi}{2}+2\pi ki)} = e^{-\frac{\pi}{2}-2\pi k} \quad (k = 0, \pm1, \pm2, \dots)$.

The main elementary functions $w = f(z) = u(x, y) + iv(x, y)$ of the complex variable $z = x + iy$ are given in Table M9.1.

TABLE M9.1

Main elementary functions $w = f(z) = u(x, y) + iv(x, y)$ of the complex variable $z = x + iy$.

No.	Complex function $w = f(z)$	Algebraic form $f(z) = u(x, y) + iv(x, y)$	Zeros of nth order	Singularities
1	z	$x + iy$	$z = 0,\ n = 1$	$z = \infty$ is a first-order pole
2	z^2	$x^2 - y^2 + i\,2xy$	$z = 0,\ n = 2$	$z = \infty$ is a second-order pole
3	$\dfrac{1}{z-(x_0+iy_0)}$ (x_0, y_0 are real numbers)	$\dfrac{x-x_0}{(x-x_0)^2+(y-y_0)^2} + i\dfrac{-(y-y_0)}{(x-x_0)^2+(y-y_0)^2}$	$z = \infty,\ n = 1$	$z = x_0 + iy_0$ is a first-order pole
4	$\dfrac{1}{z^2}$	$\dfrac{x^2-y^2}{(x^2+y^2)^2} + i\dfrac{-2xy}{(x^2+y^2)^2}$	$z = \infty,\ n = 2$	$z = 0$ is a second-order pole
5	$\sqrt{z}$	$\pm\left[\left(\dfrac{x+\sqrt{x^2+y^2}}{2}\right)^{1/2} + i\left(\dfrac{-x+\sqrt{x^2+y^2}}{2}\right)^{1/2}\right]$	$z = 0$ is a branch point	$z = 0$ is a first-order branch point $z = \infty$ is a first-order branch point
6	e^z	$e^x \cos y + ie^x \sin y$	no zeros	$z = \infty$ is an essential singular point
7	$\mathrm{Ln}\,z$	$\ln\|z\| + i(\arg z + 2k\pi)$, $k = 0, \pm1, \pm2, \dots$	$z = 1,\ n = 1$ (for the branch corresponding to $k = 0$)	Logarithmic branch points for $z = 0$, $z = \infty$
8	$\sin z$	$\sin x \cosh y + i \cos x \sinh y$	$z = \pi k,\ n = 1$ $(k = 0, \pm1, \pm2, \dots)$	$z = \infty$ is an essential singular point
9	$\cos z$	$\cos x \cosh y + i(-\sin x \sinh y)$	$z = \frac{1}{2}\pi + \pi k,\ n = 1$ $(k = 0, \pm1, \pm2, \dots)$	$z = \infty$ is an essential singular point
10	$\tan z$	$\dfrac{\sin 2x}{\cos 2x + \cosh 2y} + i\dfrac{\sinh 2y}{\cos 2x + \cosh 2y}$	$z = \pi k,\ n = 1$ $(k = 0, \pm1, \pm2, \dots)$	$z = \frac{1}{2}\pi + \pi k$ $(k = 0, \pm1, \pm2, \dots)$ are first-order poles

► **Analytic continuation.** Let two domains D_1 and D_2 have a common part γ of the boundary, and let single-valued analytic functions $f_1(z)$ and $f_2(z)$, respectively, be given in these domains. The function $f_2(z)$ is called a *direct analytic continuation* of $f_1(z)$ into the domain D_2 if there exists a function $f(z)$ analytic in the domain $D_1 \cup \gamma \cup D_2$ and satisfying the condition

$$f(z) = \begin{cases} f_1(z) & \text{for } z \in D_1, \\ f_2(z) & \text{for } z \in D_2. \end{cases} \qquad \text{(M9.2.1.6)}$$

If such a continuation is possible, then the function $f(z)$ is uniquely determined. If the domains are simply connected and the functions $f_1(z)$ and $f_2(z)$ are continuous in $D_1 \cup \gamma$ and $D_2 \cup \gamma$, respectively, and coincide on γ, then $f_2(z)$ is the direct analytic continuation of $f_1(z)$ into the domain D_2. In addition, suppose that the domains D_1 and D_2 are allowed to have common interior points. A function $f_2(z)$ is called a direct analytic continuation of $f_1(z)$ through γ if $f_1(z)$ and $f_2(z)$ are continuous in $D_1 \cup \gamma$ and $D_2 \cup \gamma$, respectively, and their values on γ coincide. At the common interior points of D_1 and D_2, the function determined by relation (M9.2.1.6) can be double-valued.

M9.2.2. Integration of Functions of Complex Variables

► **Definition and properties of the integral of a function of a complex variable.** Suppose that an oriented curve C connecting points $z = a$ and $z = b$ is given on the complex plane and a function $w = f(z)$ of the complex variable z is defined on the curve. We divide the curve C into n parts, $a = z_0, z_1, \ldots, z_{n-1}, z_n = b$, arbitrarily choose $\xi_k \in [z_k, z_{k+1}]$, and compose the integral sum

$$\sum_{k=0}^{n-1} f(\xi_k)(z_{k+1} - z_k).$$

If there exists a limit of this sum as $\max|z_{k+1} - z_k| \to 0$, independent of the way it is partitioned and the choice of the points ξ_k, then this limit is called the *integral* of the function $w = f(z)$ over the curve C and is denoted by

$$\int_C f(z)\,dz. \qquad \text{(M9.2.2.1)}$$

Properties of the integral of a function of a complex variable:

1. If α, β are arbitrary constants, then $\int_C [\alpha f(z) + \beta g(z)]\,dz = \alpha \int_C f(z)\,dz + \beta \int_C g(z)\,dz$.
2. If $\widetilde{C}$ is the same curve as C but with the opposite sense, then $\int_{\widetilde{C}} f(z)\,dz = -\int_C f(z)\,dz$.
3. If $C = C_1 \cup \cdots \cup C_n$, then $\int_C f(z)\,dz = \int_{C_1} f(z)\,dz + \cdots + \int_{C_n} f(z)\,dz$.
4. If $|f(z)| \le M$ at all points of the curve C, then the following *estimate of the absolute value of the integral* holds: $\left|\int_C f(z)\,dz\right| \le Ml$, where l is the length of the curve C.

If C is a piecewise smooth curve and $f(z)$ is bounded and piecewise continuous, then the integral (M9.2.2.1) exists. If $z = x + iy$ and $w = u(x, y) + iv(x, y)$, then the computation of the integral (M9.2.2.1) is reduced to finding two ordinary curvilinear integrals:

$$\int_C f(z)\,dz = \int_C u(x, y)\,dx - v(x, y)\,dy + i \int_C v(x, y)\,dx + u(x, y)\,dy. \qquad \text{(M9.2.2.2)}$$

Remark. Formula (M9.2.2.2) can also be written in a form convenient for memorizing:

$$\int_C f(z)\,dz = \int_C (u + iv)(dx + i\,dy).$$

If the curve C is given by the parametric equations $x = x(t)$, $y = y(t)$ $(t_1 \le t \le t_2)$, then

$$\int_C f(z)\,dz = \int_{t_1}^{t_2} f(z(t))z_t'(t)\,dt,$$

where $z = z(t) = x(t) + iy(t)$ is the complex parametric equation of the curve C.

If $f(z)$ is an analytic function in a simply connected domain D containing the points $z = a$ and $z = b$, then the *Newton–Leibniz formula* holds:

$$\int_a^b f(z)\,dz = F(b) - F(a),$$

where $F(z)$ is a primitive of the function $f(z)$, i.e., $F_z'(z) = f(z)$ in the domain D.

If $f(z)$ and $g(z)$ are analytic functions in a simply connected domain D and $z = a$ and $z = b$ are arbitrary points of the domain D, then the *formula of integration by parts* holds:

$$\int_a^b f(z)\,dg(z) = f(b)g(b) - f(a)g(a) - \int_a^b g(z)\,df(z).$$

If an analytic function $z = g(w)$ determines a single-valued mapping of a curve $\widetilde{C}$ onto a curve C, then

$$\int_C f(z)\,dz = \int_{\widetilde{C}} f(g(w))g_w'(w)\,dw.$$

► **Cauchy's theorems.**

CAUCHY'S THEOREM FOR A SIMPLY CONNECTED DOMAIN. *If a function $f(z)$ is analytic in a simply connected domain D bounded by a contour C and is continuous in $\overline{D}$, then $\int_C f(z)\,dz = 0$.*

CAUCHY'S THEOREM FOR A MULTIPLY CONNECTED DOMAIN. *If a function $f(z)$ is analytic in a multiply connected domain D bounded by a contour C consisting of several closed curves and is continuous in $\overline{D}$, then $\int_C f(z)\,dz = 0$ provided that the sense of all curves forming C is chosen in such a way that the domain D lies to the same side of the contour.*

► **Cauchy's integral and related integrals. Morera's theorem.** If a function $f(z)$ is analytic in an n-connected domain D and continuous in $\overline{D}$, and C is the boundary of D, then for any interior point z of this domain the *Cauchy integral formula* holds:

$$f(z) = \frac{1}{2\pi i}\int_C \frac{f(\xi)}{\xi - z}\,d\xi. \qquad \text{(M9.2.2.3)}$$

(Here integration is carried out in the positive sense of C; i.e., the contour C is traced so that the domain D lies to the left of the contour.) Under the same assumptions as above, the derivatives of arbitrary order of the function $f(z)$ at any interior point z of the domain are expressed as

$$f_z^{(n)}(z) = \frac{n!}{2\pi i}\int_C \frac{f(\xi)}{(\xi - z)^{n+1}}\,d\xi \qquad (n = 1, 2, \ldots). \qquad \text{(M9.2.2.4)}$$

For an arbitrary smooth curve C, not necessarily closed, and for a function $f(\xi)$ everywhere continuous on C, possibly except for finitely many points at which this function has an integrable discontinuity, the right-hand side of formula (M9.2.2.3) defines a *Cauchy-type* *integral*. The function $F(z)$ determined by a Cauchy-type integral is analytic at any point that does not belong to C. If C divides the plane into several domains, then the Cauchy-type integral generally determines different analytic functions in these domains.

Formulas (M9.2.2.3) and (M9.2.2.4) allow one to calculate the integrals

$$\int_C \frac{f(\xi)}{\xi - z}\,d\xi = 2\pi i f(z), \qquad \int_C \frac{f(\xi)}{(\xi - z)^{n+1}}\,d\xi = \frac{2\pi i}{n!} f_z^{(n)}(z). \tag{M9.2.2.5}$$

Example 1. Let us calculate the integral

$$\int_C \operatorname{Im} z\,dz,$$

where C is the semicircle $|z| = 1$, $0 \le \arg z \le \pi$ (Fig. M9.4).

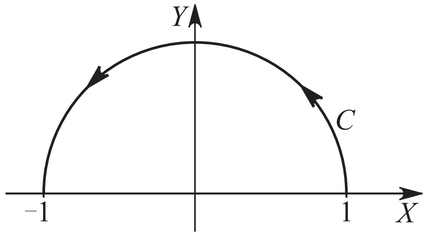

Figure M9.4. The semicircle $|z| = 1$, $0 \le \arg z \le \pi$.

Using formula (M9.2.2.2), we obtain

$$\int_C \operatorname{Im} z\,dz = \int_C y(dx + i\,dy) = \int_C y\,dx + i\int_C y\,dy = \int_1^{-1} \sqrt{1 - x^2}\,dx - i \cdot 0 = -\frac{\pi}{2}.$$

Example 2. Let us calculate the integral

$$\int_C \frac{dz}{z - z_0},$$

where C is the circle of radius R centered at a point z_0 with counterclockwise sense.

Using the integral formula (M9.2.2.5), we obtain

$$\int_C \frac{1}{z - z_0}\,dz = 2\pi i.$$

Example 3. Let us calculate the integral

$$\int_C \frac{dz}{z^2 + 1},$$

where C is the circle of unit radius centered at the point i with counterclockwise sense.

To apply the Cauchy integral formula (M9.2.2.3), we transform the integrand as follows:

$$\frac{1}{1 + z^2} = \frac{1}{(z - i)(z + i)} = \frac{1}{z + i}\,\frac{1}{z - i} = \frac{f(z)}{z - i}, \quad f(z) = \frac{1}{z + i}.$$

The function $f(z) = 1/(z + i)$ is analytic in the interior of the domain under study and on its boundary; hence the Cauchy integral formula (M9.2.2.3) and the first of formulas (M9.2.2.5) hold. From the latter formula, we obtain

$$\int_C \frac{dz}{z^2 + 1} = \int_C \frac{f(z)}{z - i}\,dz = 2\pi i f(i) = 2\pi i \frac{1}{2i} = \pi.$$

Formulas (M9.2.2.3) and (M9.2.2.4) imply the *Cauchy inequalities*

$$|f_z^{(n)}(z)| \le \frac{n!}{2\pi}\left|\int_C \frac{f(\xi)}{(\xi - z)^{n+1}}\,d\xi\right| \le \frac{n!Ml}{2\pi R^{n+1}},$$

where $M = \max_{z\in D}\bigl|f(z)\bigr|$ is the maximum modulus of the function $f(z)$ in the domain D, R is the distance from the point z to the boundary C, and l is the length of the boundary C.

If, in particular, $f(z)$ is analytic in the disk $D = |z - z_0| < R$, and bounded in $\bar{D}$, then we obtain the inequality

$$|f_z^{(n)}(z_0)| \le \frac{n!M}{R^n} \quad (n = 0, 1, 2, \dots).$$

MORERA'S THEOREM. *If a function $f(z)$ is continuous in a simply connected domain D and $\int_C f(z)\,dz = 0$ for any closed curve C lying in D, then $f(z)$ is analytic in the domain D.*

M9.2.3. Taylor and Laurent Series

► **Taylor series.** If a series

$$\sum_{n=0}^{\infty} f_n(z) \qquad \text{(M9.2.3.1)}$$

of analytic functions in a simply connected domain D converges uniformly in this domain, then its sum is analytic in the domain D.

If a series (M9.2.3.1) of functions analytic in a domain D and continuous in $\overline{D}$ converges uniformly in $\overline{D}$, then it can be differentiated termwise any number of times and can be integrated termwise over any piecewise smooth curve C lying in D.

ABEL'S THEOREM. *If the power series*

$$\sum_{n=0}^{\infty} c_n(z-a)^n \qquad \text{(M9.2.3.2)}$$

converges at a point z_0, then it also converges at any point z satisfying the condition $|z - a| < |z_0 - a|$. Moreover, the series converges uniformly in any disk $|z - a| \le q|z_0 - a|$, where $0 < q < 1$.

It follows from Abel's theorem that the domain of convergence of a power series is an open disk centered at the point a; moreover, this disk can fill the entire plane. The radius of this disk is called the *radius of convergence* of a power series. The sum of the power series inside the disk of convergence is an analytic function.

Remark. The radius of convergence R can be found by the *Cauchy–Hadamard formula*

$$\frac{1}{R} = \overline{\lim_{n\to\infty}} \sqrt[n]{|c_n|},$$

where $\overline{\lim}$ denotes the upper limit.

If a function $f(z)$ is analytic in the open disk D of radius R centered at a point $z = a$, then this function can be represented in this disk by its *Taylor series*

$$f(z) = \sum_{n=0}^{\infty} c_n(z-a)^n,$$

whose coefficients are determined by the formulas

$$c_n = \frac{f_z^{(n)}(a)}{n!} = \frac{1}{2\pi i}\int_C \frac{f(\xi)}{(\xi - a)^{n+1}}\,d\xi \qquad (n = 0, 1, 2, \dots),$$

where C is the circle $|z-a| = qR$, $0 < q < 1$. In any closed domain belonging to the disk D, the Taylor series converges uniformly. Any power series expansion of an analytic function is its Taylor expansion. The Taylor series expansions of some elementary functions in powers of z are as follows:

$$e^z = 1 + z + \frac{z^2}{2!} + \frac{z^3}{3!} + \dots \quad (|z| < \infty), \tag{M9.2.3.3}$$

$$\cos z = 1 - \frac{z^2}{2!} + \frac{z^4}{4!} - \dots, \quad \sin z = z - \frac{z^3}{3!} + \frac{z^5}{5!} - \dots \quad (|z| < \infty), \tag{M9.2.3.4}$$

$$\cosh z = 1 + \frac{z^2}{2!} + \frac{z^4}{4!} + \dots, \quad \sinh z = z + \frac{z^3}{3!} + \frac{z^5}{5!} + \dots \quad (|z| < \infty), \tag{M9.2.3.5}$$

$$\ln(1 + z) = z - \frac{z^2}{2} + \frac{z^3}{3} - \dots \quad (|z| < 1), \tag{M9.2.3.6}$$

$$(1 + z)^a = 1 + az + \frac{a(a-1)}{2!}z^2 + \frac{a(a-1)(a-2)}{3!}z^3 + \dots \quad (|z| < 1). \tag{M9.2.3.7}$$

The last two expansions are valid for the single-valued branches for which the values of the functions for $z = 0$ are equal to 0 and 1, respectively.

Remark. Series expansions (M9.2.3.3)–(M9.2.3.7) coincide with analogous expansions of the corresponding elementary functions of the real variable (see Subsection M8.3.2).

To obtain the Taylor series for other branches of the multi-valued function $\mathrm{Ln}(1 + z)$, one has to add the numbers $2k\pi i$, $k = \pm1, \pm2, \dots$ to the expression in the right-hand side:

$$\mathrm{Ln}(1 + z) = 2k\pi i + z - \frac{z^2}{2} + \frac{z^3}{3} - \dots.$$

► **Laurent series.** The domain of convergence of the function series $\sum\limits_{n=-\infty}^{\infty} c_n(z-a)^n$ is a circular annulus $K : r < |z - a| < R$, where $0 \le r < R \le \infty$. The sum of the series is an analytic function in the annulus of convergence. Conversely, in any annulus K where the function $f(z)$ is analytic, this function can be represented by the *Laurent series* expansion

$$f(z) = \sum_{n=-\infty}^{\infty} c_n(z-a)^n$$

with coefficients determined by the formulas

$$c_n = \frac{1}{2\pi i} \int_\gamma \frac{f(\xi)}{(\xi - a)^{n+1}}\, d\xi \quad (n = 0, \pm1, \pm2, \dots), \tag{M9.2.3.8}$$

where γ is the circle $|z-a| = \rho$, $r < \rho < R$. In any closed domain contained in the annulus K, the Laurent series converges uniformly.

The part of the Laurent series with negative numbers,

$$\sum_{n=-\infty}^{-1} c_n(z-a)^n = \sum_{n=1}^{\infty} \frac{c_{-n}}{(z-a)^n},$$

is called its *principal part*, and the part with nonnegative numbers,

$$\sum_{n=0}^{\infty} c_n(z-a)^n,$$

is called the *regular part*. Any expansion of an analytic function in positive and negative powers of $z - a$ is its Laurent expansion.

Example 1. Let us consider Laurent series expansions of the function

$$f(z)=\frac{1}{z(1-z)}$$

in a Laurent series in the domain $0<|z|<1$. This function is analytic in the annulus $0<|z|<1$ and hence can be expanded in the corresponding Laurent series. We write this function as the sum of elementary fractions:

$$f(z)=\frac{1}{z(1-z)}=\frac{1}{z}+\frac{1}{1-z}.$$

Since $|z|<1$, we can use formula (M9.2.3.7) and obtain the expansion

$$\frac{1}{z(1-z)}=\frac{1}{z}+1+z+z^2+\cdots$$

Example 2. Let us consider Laurent series expansions of the function

$$f(z)=e^{1/z}$$

in a Laurent series in a neighborhood of the point $a=0$. To this end, we use the expansion (M9.2.3.3), where we should replace z by $1/z$. Thus we obtain

$$e^{1/z}=1+\frac{1}{1!\,z}+\frac{1}{2!\,z^2}+\cdots+\frac{1}{n!\,z^n}+\cdots\qquad(z\neq 0).$$

M9.2.4. Zeros and Isolated Singularities of Analytic Functions

► **Zeros of analytic functions.** A point $z=a$ is called a *zero* of a function $f(z)$ if $f(a)=0$. If $f(z)$ is analytic at the point a and is not zero identically, then the least order of nonzero coefficients in the Taylor expansion of $f(z)$ centered at a, in other words, the number n of the first nonzero derivative $f^{(n)}(a)$, is called the *order of zero* of this function. In a neighborhood of a zero a of order n, the Taylor expansion of $f(z)$ has the form

$$f(z)=c_n(z-a)^n+c_{n+1}(z-a)^{n+1}+\ldots\qquad(c_n\neq 0,\ n\geq 1).$$

In this case, $f(z)=c_n(z-a)^n g(z)$, where the function $g(z)$ is analytic at the point a and $g(a)\neq 0$. A first-order zero is said to be *simple*. The point $z=\infty$ is a zero of order n for a function $f(z)$ if $z=0$ is a zero of order n for $F(z)=f(1/z)$.

If a function $f(z)$ is analytic in a neighborhood of its zero a and is not identically zero in any neighborhood of a, then there exists a neighborhood of a in which $f(z)$ does not have any zeros other than a.

UNIQUENESS THEOREM. *If functions $f(z)$ and $g(z)$ are analytic in a domain D and their values coincide on some sequence a_k of points converging to an interior point a of the domain D, then $f(z)\equiv g(z)$ everywhere in D.*

ROUCHÉ'S THEOREM. *If functions $f(z)$ and $g(z)$ are analytic in a simply connected domain D bounded by a curve C, are continuous in $\overline{D}$, and satisfy the inequality $|f(z)|>|g(z)|$ on C, then the functions $f(z)$ and $f(z)+g(z)$ have the same number of zeros in D.*

► **Isolated singularities of analytic functions.** A point a is called an *isolated singularity* of a single-valued analytic function $f(z)$ if there exists a neighborhood of this point in which $f(z)$ is analytic everywhere except for the point a itself. The point a is called

1. A *removable singularity* if $\lim\limits_{z\to a} f(z)$ exists and is finite.
2. A *pole* if $\lim\limits_{z\to a} f(z)=\infty$.
3. An *essential singularity* if $\lim\limits_{z\to a} f(z)$ does not exist.

A necessary and sufficient condition for a point a to be a removable singularity of a function $f(z)$ is that the Laurent expansion of $f(z)$ around a does not contain the principal part.

If a function $f(z)$ is bounded in a neighborhood of an isolated singularity a, then a is a removable singularity of this function.

A necessary and sufficient condition for a point a to be a pole of a function $f(z)$ is that the principal part of the Laurent expansion of $f(z)$ around a contains finitely many terms:

$$f(z)=\frac{c_{-n}}{(z-a)^n}+\dots+\frac{c_{-1}}{(z-a)}+\sum_{k=0}^{\infty}c_k(z-a)^k. \tag{M9.2.4.1}$$

The *order of a pole* a of a function $f(z)$ is defined to be the order of the zero of the function $F(z)=1/f(z)$. If $c_{-n}\neq 0$ in expansion (M9.2.4.1), then the order of the pole a of the function $f(z)$ is equal to n. For $n=1$, we have a *simple pole*.

A necessary and sufficient condition for a point a to be an essential singularity of a function $f(z)$ is that the principal part of the Laurent expansion of $f(z)$ around a contains infinitely many nonzero terms.

SOKHOTSKI'S THEOREM. *If a is an essential singularity of a function $f(z)$, then for each complex number A there exists a sequence of points $z_k\to a$ such that $f(z_k)\to A$.*

Example. Let us consider some functions with singular points of different kind.

1°. The function $f(z)=(1-\cos z)/z^2$ has a removable singularity at the origin, since its Laurent expansion about the origin,

$$\frac{1-\cos z}{z^2}=\frac{1}{2}-\frac{z^2}{24}+\frac{z^4}{720}-\dots,$$

does not contain the principal part.

2°. The function $f(z)=1/(1+e^{z^2})$ has infinitely many poles at the points $z=\pm\sqrt{(2k+1)\pi i}$ $(k=0,\pm1,\pm2,\dots)$. All these poles are simple poles, since the function $1/f(z)=1+e^{z^2}$ has simple zeros at these points. (Its derivative is nonzero at these points.)

3°. The function $f(z)=\sin(1/z)$ has an essential singularity at the origin, since the principal part of its Laurent expansion

$$\sin\frac{1}{z}=\frac{1}{z}-\frac{1}{z^3 3!}+\dots$$

contains infinitely many terms.

The following two simplest classes of single-valued analytic functions are distinguished according to the character of singular points.

1. *Entire functions.* A function $f(z)$ is said to be *entire* if it does not have singular points in the finite part of the complex plane. An entire function can be represented by an everywhere convergent power series

$$f(z)=\sum_{n=0}^{\infty}c_n z^n.$$

An entire function can have only one singular point at $z=\infty$. If this singularity is a pole of order n, then $f(z)$ is a polynomial of degree n. If $z=\infty$ is an essential singularity, then $f(z)$ is called an *entire transcendental function*. If $z=\infty$ is a regular point (i.e., $f(z)$ is analytic for all z), then $f(z)$ is constant (*Liouville's theorem*). All polynomials, the exponential function, $\sin z$, $\cos z$, etc. are examples of entire functions. Sums, differences, and products of entire functions are themselves entire functions.

2. *Meromorphic functions.* A function $f(z)$ is said to be *meromorphic* if it does not have any singularities except for poles. The number of these poles in each finite closed domain D is always finite.

Suppose that a function $f(z)$ is analytic in a neighborhood of the point at infinity. The definition of singular points can be generalized to this function without any changes. But the criteria for the type of a singular point at infinity related to the Laurent expansion are different.

THEOREM. *In the case of a removable singularity at the point at infinity, the Laurent expansion of a function $f(z)$ in a neighborhood of this point does not contain positive powers of z. In the case of a pole, it contains finitely many positive powers of z. In the case of an essential singularity, it contains infinitely many powers of z.*

Let $f(z)$ be a multi-valued function defined in a neighborhood D of a point $z = a$ except possibly for the point a itself, and let $f_1(z)$, $f_2(z)$, ... be its branches, which are single-valued continuous functions in the domain where they are defined. The point a is called a *branch point (ramification point)* of the function $f(z)$ if $f(z)$ passes from one branch to another as the point z goes along a closed curve around the point z in a neighborhood of D. If the original branch is reached again after going around this curve m times (in the same sense), then the number $m-1$ is called the *order* of the branch point, and the point a itself is called a *branch point of order* $m-1$.

If all branches $f_k(z)$ tend to the same finite or infinite limit as $z \to a$, then the point a is called an *algebraic* branch point. (For example, the point $z = 0$ is an algebraic branch point of the function $f(z) = \sqrt[m]{z}$.) In this case, the single-valued function

$$F(z) = f(z^m + a)$$

has a regular point or a pole for $z = 0$.

If the limit of $f_k(z)$ as $z \to a$ does not exist, then the point a is called a *transcendental* branch point. For example, the point $z = 0$ is a transcendental branch point of the function $f(z) = \exp(\sqrt[m]{1/z})$.

In a neighborhood of a branch point a of finite order, the function $f(z)$ can be expanded in a *fractional power series* (*Puiseux series*)

$$f(z) = \sum_{k=-\infty}^{\infty} c_k (z-a)^{k/m}. \qquad \text{(M9.2.4.2)}$$

If a new branch is obtained each time after going around this curve (in the same sense), then the point a is called a *branch point of infinite order (a logarithmic branch point)*. For example, the points $z = 0$ and $z = \infty$ are logarithmic branch points of the multi-valued function $w = \operatorname{Ln} z$. A logarithmic branch point is classified as a transcendental branch point.

For $a \neq \infty$, the expansion (M9.2.4.2) contains finitely many terms with negative k (infinitely many in the case of a transcendental point).

M9.2.5. Residues. Calculation of Definite Integrals

► **Residue of an analytic function at an isolated singular point.** The *residue* $\operatorname{res} f(a)$ of a function $f(z)$ at an isolated singularity a is defined as the number

$$\operatorname{res} f(a) = \frac{1}{2\pi i} \oint_C f(z)\,dz, \qquad \text{(M9.2.5.1)}$$

where the integral is taken in the positive sense over a contour C surrounding the point a and containing no other singularities of $f(z)$ in the interior.

Remark. Residues are sometimes denoted by $\operatorname{res}[f(z); a]$ or $\operatorname{res}_{z=a} f(z)$.

The residue $\operatorname{res} f(a)$ of a function $f(z)$ at a singularity a is equal to the coefficient of $(z-a)^{-1}$ in the Laurent expansion of $f(z)$ in a neighborhood of the point a,

$$\operatorname{res} f(a) = \frac{1}{2\pi i} \oint_C f(z)\,dz = c_{-1}.$$

Basic rules for finding the residues:

1. The residue of a function at a removable singularity is zero.
2. If a is a pole of order n, then

$$\operatorname{res} f(a) = \frac{1}{(n-1)!} \lim_{z\to a} \frac{d^{n-1}}{dz^{n-1}} \big[f(z)(z-a)^n\big]. \qquad \text{(M9.2.5.2)}$$

3. For a simple pole ($n = 1$),

$$\operatorname{res} f(a) = \lim_{z\to a} \big[f(z)(z-a)\big].$$

4. If $f(z)$ is the quotient of two analytic functions,

$$f(z) = \frac{\varphi(z)}{\psi(z)},$$

in a neighborhood of a point a and $\varphi(a) \neq 0$, $\psi(a) = 0$, but $\psi'_z(a) \neq 0$ (i.e., a is a simple pole of $f(z)$), then

$$\operatorname{res} f(a) = \frac{\varphi(a)}{\psi'_z(a)}. \qquad \text{(M9.2.5.3)}$$

5. If a is an essential singularity of $f(z)$, then to obtain $\operatorname{res} f(a)$, one has to find the coefficient c_{-1} in the Laurent expansion of $f(z)$ in a neighborhood of a.

► Basic theorems on residues.

A function $f(z)$ is said to be continuous on the boundary C of the domain D if for each boundary point z_0 there exists a limit $\lim\limits_{z\to z_0} f(z) = f(z_0)$ as $z \to z_0$, $z \in D$.

CAUCHY'S RESIDUE THEOREM. *Let $f(z)$ be a function continuous on the boundary C of a domain D and analytic in the interior of D everywhere except for finitely many points $a_1, \ldots, a_n$. Then*

$$\int_C f(z)\,dz = 2\pi i \sum_{k=1}^{n} \operatorname{res} f(a_k), \qquad \text{(M9.2.5.4)}$$

where the integral is taken in the positive sense of C.

The *logarithmic residue* of a function $f(z)$ at a point a is by definition the residue of its logarithmic derivative

$$\big[\ln f(z)\big]'_z = \frac{f'_z(z)}{f(z)}.$$

THEOREM. *The logarithmic derivative $f'_z(z)/f(z)$ has first-order poles at the zeros and poles of $f(z)$. Moreover, the logarithmic residue of $f(z)$ at a zero or a pole of $f(z)$ is equal to the order of the zero or minus the order of the pole, respectively.*

The residue of a function $f(z)$ at infinity is defined as

$$\operatorname{res} f(\infty) = \frac{1}{2\pi i} \oint_\Gamma f(z)\,dz,$$

where Γ is a circle of sufficiently large radius $|z| = \rho$ and the integral is taken in the clockwise sense (so that the neighborhood of the point $z = \infty$ remains to the left of the contour, just as in the case of a finite point).

The residue of $f(z)$ at infinity is equal to minus the coefficient of z^{-1} in the Laurent expansion of $f(z)$ in a neighborhood of the point $z = \infty$,

$$\operatorname{res} f(\infty) = -c_{-1}.$$

THEOREM. *If a function $f(z)$ has finitely many singular points in the extended complex plane, then the sum of all its residues, including the residue at infinity, is zero:*

$$\operatorname{res} f(\infty) + \sum_{k=1}^{n} \operatorname{res} f(a_k) = 0, \qquad \text{(M9.2.5.5)}$$

where $a_1, \dots, a_n$ are finite singular points.

Example 1. Let us calculate the integral

$$\oint_C \frac{\ln(z+2)}{z^2}\,dz,$$

where C is the circle $|z| = \frac{1}{2}$.

In the disk $|z| \le \frac{1}{2}$, there is only one singular point of the integrand, $z = 0$, which is a second-order pole. The residue of $f(z)$ at $z = 0$ is calculated by the formula (M9.2.5.2)

$$\operatorname{res} f(0) = \lim_{z\to 0}\Bigl[z^2 \frac{\ln(z+2)}{z^2}\Bigr]'_z = \lim_{z\to 0}[\ln(z+2)]'_z = \lim_{z\to 0} \frac{1}{z+2} = \frac{1}{2}.$$

Using formula (M9.2.5.1), we obtain

$$\frac{1}{2} = \frac{1}{2\pi i} \oint_C \frac{\ln(z+2)}{z^2}\,dz, \qquad \oint_C \frac{\ln(z+2)}{z^2}\,dz = \pi i.$$

► **Jordan's lemma. Calculation of definite integrals using residues.** Suppose that we need to calculate the integral of a real function $f(x)$ over a (finite or infinite) interval (a, b). Let us supplement the interval (a, b) with a curve Γ that, together with (a, b), bounds a domain D, and then analytically continue the function $f(x)$ into $\overline{D}$. Then the residue theorem can be applied to this analytic continuation of $f(z)$, and by this theorem

$$\int_a^b f(x)\,dx + \int_\Gamma f(z)\,dz = 2\pi i \Lambda,$$

where Λ is the sum of residues of $f(z)$ in D. If $\int_\Gamma f(z)\,dz$ can be calculated or expressed in terms of the desired integral $\int_a^b f(x)\,dx$, then the problem will be solved.

When calculating integrals of the form $\int_{-\infty}^{\infty} f(x)\,dx$, one should apply (M9.2.5.4) to the contour C that consists of the interval $(-R, R)$ of the real axis and the arc C_R of the semicircle $|z| = R$ in the upper half-plane. Sometimes, it is only possible to find the limit as $R \to \infty$ of the integral over the contour C_R rather than to calculate it, and often it turns out that the limit of this integral is equal to zero.

LEMMA. *If a function $f(z)$ is analytic for $|z| > R_0$ and $zf(z) \to 0$ as $|z| \to \infty$ for $y \ge 0$, then*

$$\lim_{R\to\infty} \int_{C_R} f(z)\,dz = 0,$$

where C_R is the arc of the semicircle $|z| = R$ in the upper half-plane.

THEOREM. *Let a function $f(x)$ be defined on the whole real axis $-\infty < x < \infty$ and let it can be analytically continued to the upper half-plane $\operatorname{Im} z > 0$ so that the continuation $f(z)$ satisfies the conditions of the previous lemma. Then the improper integral $\int_{-\infty}^{\infty} f(x)\,dx$ exists and is equal to*

$$\int_{-\infty}^{\infty} f(x)\,dx = 2\pi i \sum_{k=1}^{n} \operatorname{res} f(a_k), \tag{M9.2.5.6}$$

where the a_k are singular points of $f(z)$ in the upper half-plane.

Example 2. Calculate the integral

$$I = \int_{-\infty}^{\infty} \frac{dx}{1+x^4}.$$

The analytic continuation of the integrand into the upper half-plane is $f(z) = (1+z^4)^{-1}$; it satisfies the conditions of the above lemma. The function $f(z)$ has two singular points, $a_1 = e^{i\pi/4}$ and $a_2 = e^{i3\pi/4}$, in the upper half-plane (both points are first-order poles). Using formulas (M9.2.5.3) and (M9.2.5.6), one finds

$$I = 2\pi i \left(\frac{1}{4z^3}\bigg|_{z=e^{i\pi/4}} + \frac{1}{4z^3}\bigg|_{z=e^{i3\pi/4}} \right) = \frac{\pi\sqrt{2}}{2}.$$

JORDAN'S LEMMA. *If a function $g(z)$ tends to zero uniformly with respect to $\arg z$ along a sequence of circular arcs $C_{R_n} : |z| = R_n$, $\operatorname{Im} z > -a$ (where $R_n \to \infty$ and a is fixed), then*

$$\lim_{n\to\infty} \int_{C_{R_n}} g(z) e^{i\lambda z}\,dz = 0$$

for any positive number λ.

Example 3 (Laplace integral). To calculate the integral

$$\int_0^{\infty} \frac{\cos x}{x^2+a^2}\,dx,$$

one uses the auxiliary function

$$f(z) = \frac{e^{iz}}{z^2+a^2} = g(z)e^{iz}, \quad g(z) = \frac{1}{z^2+a^2}$$

and the contour shown in Fig. M9.5. Since $g(z)$ satisfies the inequality $|g(z)| < (R^2 - a^2)^{-1}$ on C_R, it follows that this function uniformly tends to zero as $R \to \infty$, and by Jordan's lemma with $\lambda = 1$ we obtain

$$\int_{C_R} f(z)\,dz = \int_{C_R} g(z)e^{iz}\,dz \to 0$$

as $R \to \infty$.

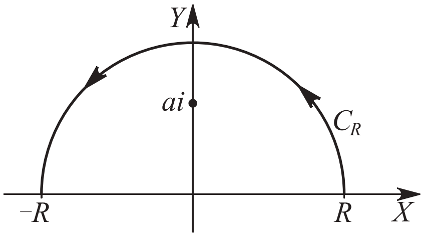

Figure M9.5. The contour for the calculation of the Laplace integral.

By the residue theorem

$$\int_{-R}^{R} \frac{e^{ix}}{x^2+a^2}\,dx + \int_{C_R} f(z)\,dz = 2\pi i\,\frac{e^{-a}}{2ai}$$

for any $R > a$. (The residue at the singular point $z = ai$ of the function $f(z)$, which is a first-order pole and the only singular point of this function lying inside the contour, can be calculated by formula (M9.2.5.3).) In the limit as $R \to \infty$, we obtain

$$\int_{-\infty}^{\infty} \frac{e^{ix}}{x^2+a^2}\,dx = \frac{\pi}{ae^a}.$$

Separating the real part and using the fact that the function is even, we obtain

$$\int_{0}^{\infty} \frac{\cos x}{x^2+a^2}\,dx = \frac{\pi}{2ae^a}.$$

Chapter M10

Integral Transforms

M10.1. General Form of Integral Transforms. Inversion Formulas

Normally an integral transform has the form

$$\widetilde{f}(\lambda) = \int_a^b \varphi(x, \lambda) f(x)\, dx.$$

The function $\widetilde{f}(\lambda)$ is called the *transform* of the function $f(x)$ and $\varphi(x, \lambda)$ is called the *kernel* of the integral transform. The function $f(x)$ is called the *inverse transform* of $\widetilde{f}(\lambda)$. The limits of integration a and b are real numbers (usually, $a = 0$, $b = \infty$ or $a = -\infty$, $b = \infty$). For brevity, we rewrite the integral transform as follows: $\widetilde{f}(\lambda) = \mathcal{L}\{f(x)\}$.

General properties of integral transforms (linearity):

$$\mathcal{L}\{kf(x)\} = k\mathcal{L}\{f(x)\},$$
$$\mathcal{L}\{f(x) \pm g(x)\} = \mathcal{L}\{f(x)\} \pm \mathcal{L}\{g(x)\}.$$

Here, k is an arbitrary constant; it is assumed that integral transforms of the functions $f(x)$ and $g(x)$ exist.

In Subsections M10.2–M10.4, the most popular (Laplace, Fourier, Mellin, etc.) integral transforms are described. These subsections also describe the corresponding inversion formulas, which normally have the form

$$f(x) = \int_{\mathcal{C}} \psi(x, \lambda) \widetilde{f}(\lambda)\, d\lambda$$

and make it possible to recover $f(x)$ if $\widetilde{f}(\lambda)$ is given. The integration path $\mathcal{C}$ can lie either on the real axis or in the complex plane.

In many cases, to evaluate the integrals in the inversion formula—in particular, to find the inverse Laplace, Mellin, and Fourier transforms—methods of the theory of functions of a complex variable can be applied, including the theorems about residue and Jordan's lemma, which are outlined in Subsection M9.2.5.

M10.2. Laplace Transform

M10.2.1. Laplace Transform and the Inverse Laplace Transform

► **Laplace transform.** The *Laplace transform* of an arbitrary (complex-valued) function $f(x)$ of a real variable x ($x \geq 0$) is defined by

$$\widetilde{f}(p) = \int_0^\infty e^{-px} f(x)\, dx, \qquad \text{(M10.2.1.1)}$$

where $p = s + i\sigma$ is a complex variable.

The Laplace transform exists for any continuous or piecewise-continuous function satisfying the condition $|f(x)| < Me^{\sigma_0 x}$ with some $M > 0$ and $\sigma_0 \geq 0$. In the following, σ_0 often means the greatest lower bound of the possible values of σ_0 in this estimate; this value is called the *growth exponent* of the function $f(x)$.

For any $f(x)$, the transform $\widetilde{f}(p)$ is defined in the half-plane $\operatorname{Re} p > \sigma_0$ and is analytic there.

For brevity, we shall write formula (M10.2.1.1) as follows:

$$\widetilde{f}(p) = \mathfrak{L}\bigl\{f(x)\bigr\} \qquad \text{or} \qquad \widetilde{f}(p) = \mathfrak{L}\bigl\{f(x),\, p\bigr\}.$$

► **Inverse Laplace transform.** Given the transform $\widetilde{f}(p)$, the function $f(x)$ can be found by means of the inverse Laplace transform

$$f(x) = \frac{1}{2\pi i}\int_{c-i\infty}^{c+i\infty} \widetilde{f}(p)e^{px}\,dp, \qquad i^2 = -1, \tag{M10.2.1.2}$$

where the integration path is parallel to the imaginary axis and lies to the right of all singularities of $\widetilde{f}(p)$, which corresponds to $c > \sigma_0$.

The integral in inversion formula (M10.2.1.2) is understood in the sense of the Cauchy principal value:

$$\int_{c-i\infty}^{c+i\infty} \widetilde{f}(p)e^{px}\,dp = \lim_{\omega\to\infty}\int_{c-i\omega}^{c+i\omega} \widetilde{f}(p)e^{px}\,dp.$$

In the domain $x < 0$, formula (M10.2.1.2) gives $f(x) \equiv 0$.

Formula (M10.2.1.2) holds for continuous functions. If $f(x)$ has a (finite) jump discontinuity at a point $x = x_0 > 0$, then the right-hand side of (M10.2.1.2) evaluates to $\frac{1}{2}[f(x_0 - 0) + f(x_0 + 0)]$ at this point (for $x_0 = 0$, the first term in the square brackets must be omitted).

For brevity, we write the Laplace inversion formula (M10.2.1.2) as follows:

$$f(x) = \mathfrak{L}^{-1}\bigl\{\widetilde{f}(p)\bigr\} \qquad \text{or} \qquad f(x) = \mathfrak{L}^{-1}\bigl\{\widetilde{f}(p),\, x\bigr\}.$$

There are tables of direct and inverse Laplace transforms (see Sections S2.1 and S2.2), which are handy in solving linear differential and integral equations.

M10.2.2. Main Properties of the Laplace Transform. Inversion Formulas for Some Functions

► **Convolution theorem. Main properties of the Laplace transform.**

1°. The *convolution* of two functions $f(x)$ and $g(x)$ is defined as an integral of the form $\int_0^x f(t)g(x-t)\,dt$, and is usually denoted by $f(x) * g(x)$, so that

$$f(x) * g(x) = \int_0^x f(t)\,g(x-t)\,dt.$$

By performing substitution $x - t = u$, we see that the convolution is symmetric with respect to the convolved functions: $f(x) * g(x) = g(x) * f(x)$.

The *convolution theorem* states that

$$\mathfrak{L}\bigl\{f(x) * g(x)\bigr\} = \mathfrak{L}\bigl\{f(x)\bigr\}\,\mathfrak{L}\bigl\{g(x)\bigr\}$$

and is frequently applied to solve Volterra equations with kernels depending on the difference of the arguments.

2°. The main properties of the correspondence between functions and their Laplace transforms are gathered in Table M10.1.

3°. The Laplace transforms of some functions are listed in Table M10.2; for more detailed tables, see Section S2.1 and the list of references at the end of this chapter.

► **Inverse transforms of rational functions.** Consider the important case in which the transform is a rational function of the form

$$\widetilde{f}(p) = \frac{R(p)}{Q(p)}, \tag{M10.2.2.1}$$

where $Q(p)$ and $R(p)$ are polynomials in the variable p and the degree of $Q(p)$ exceeds that of $R(p)$.

Assume that the zeros of the denominator are simple, i.e.,

$$Q(p) \equiv \text{const}\,(p-\lambda_1)(p-\lambda_2)\dots(p-\lambda_n).$$

Then the inverse transform can be determined by the formula

$$f(x) = \sum_{k=1}^{n} \frac{R(\lambda_k)}{Q'(\lambda_k)} \exp(\lambda_k x), \tag{M10.2.2.2}$$

where the primes denote the derivatives.

If $Q(p)$ has multiple zeros, i.e.,

$$Q(p) \equiv \text{const}\,(p-\lambda_1)^{s_1}(p-\lambda_2)^{s_2}\dots(p-\lambda_m)^{s_m},$$

then

$$f(x) = \sum_{k=1}^{m} \frac{1}{(s_k-1)!} \lim_{p\to s_k} \frac{d^{s_k-1}}{dp^{s_k-1}} \bigl[(p-\lambda_k)^{s_k}\widetilde{f}(p)e^{px}\bigr]. \tag{M10.2.2.3}$$

Example 1. The transform

$$\widetilde{f}(p) = \frac{b}{p^2-a^2} \qquad (a \text{ and } b \text{ real numbers})$$

can be represented as the fraction (M10.2.2.1) with $R(p) = b$ and $Q(p) = (p-a)(p+a)$. The denominator $Q(p)$ has two simple roots, $\lambda_1 = a$ and $\lambda_2 = -a$. Using formula (M10.2.2.2) with $n = 2$ and $Q'(p) = 2p$, we obtain the inverse transform in the form

$$f(x) = \frac{b}{2a}e^{ax} - \frac{b}{2a}e^{-ax} = \frac{b}{a}\sinh(ax).$$

Example 2. The transform

$$\widetilde{f}(p) = \frac{b}{p^2+a^2} \qquad (a \text{ and } b \text{ real numbers})$$

can be written as the fraction (M10.2.2.1) with $R(p) = b$ and $Q(p) = (p-ia)(p+ia)$, $i^2 = -1$. The denominator $Q(p)$ has two simple pure imaginary roots, $\lambda_1 = ia$ and $\lambda_2 = -ia$. Using formula (M10.2.2.2) with $n = 2$, we find the inverse transform:

$$f(x) = \frac{b}{2ia}e^{iax} - \frac{b}{2ia}e^{-iax} = \frac{b}{a}\sin(ax).$$

Example 3. The transform

$$\widetilde{f}(p) = ap^{-n},$$

where n is a positive integer, can be written as the fraction (M10.2.2.1) with $R(p) = a$ and $Q(p) = p^n$. The denominator $Q(p)$ has one root of multiplicity n, $\lambda_1 = 0$. By formula (M10.2.2.3) with $m = 1$ and $s_1 = n$, we find the inverse transform:

$$f(x) = \frac{a}{(n-1)!}x^{n-1}.$$

Remark. Fairly detailed tables of inverse Laplace transforms can be found in Section S2.2.

TABLE M10.1
Main properties of the Laplace transform.

No.	Function	Laplace transform	Operation
1	$af_1(x)+bf_2(x)$	$a\widetilde{f}_1(p)+b\widetilde{f}_2(p)$	Linearity
2	$f(x/a),\ a>0$	$a\widetilde{f}(ap)$	Scaling
3	$f(x-a)$, $f(x-a)\equiv 0$ for $x<a$	$e^{-ap}\widetilde{f}(p)$	Shift of the argument
4	$x^n f(x);\ n=1,2,\ldots$	$(-1)^n\widetilde{f}_p^{(n)}(p)$	Differentiation of the transform
5	$\dfrac{1}{x}f(x)$	$\displaystyle\int_p^\infty \widetilde{f}(q)\,dq$	Integration of the transform
6	$e^{ax}f(x)$	$\widetilde{f}(p-a)$	Shift in the complex plane
7	$f'_x(x)$	$p\widetilde{f}(p)-f(+0)$	Differentiation
8	$f_x^{(n)}(x)$	$p^n\widetilde{f}(p)-\sum\limits_{k=1}^{n}p^{n-k}f_x^{(k-1)}(+0)$	Differentiation
9	$x^m f_x^{(n)}(x),\ m=1,2,\ldots$	$(-1)^m\dfrac{d^m}{dp^m}\Big[p^n\widetilde{f}(p)-\sum\limits_{k=1}^{n}p^{n-k}f_x^{(k-1)}(+0)\Big]$	Differentiation
10	$\dfrac{d^n}{dx^n}\big[x^m f(x)\big],\ \ m\ge n$	$(-1)^m p^n\dfrac{d^m}{dp^m}\widetilde{f}(p)$	Differentiation
11	$\displaystyle\int_0^x f(t)\,dt$	$\dfrac{\widetilde{f}(p)}{p}$	Integration
12	$\displaystyle\int_0^x f_1(t)f_2(x-t)\,dt$	$\widetilde{f}_1(p)\widetilde{f}_2(p)$	Convolution

TABLE M10.2
The Laplace transforms of some functions.

No.	Function, $f(x)$	Laplace transform, $\widetilde{f}(p)$	Remarks
1	1	$1/p$	
2	x^n	$\dfrac{n!}{p^{n+1}}$	$n=1,\ 2,\ \ldots$
3	x^a	$\Gamma(a+1)p^{-a-1}$	$a>-1$
4	e^{-ax}	$(p+a)^{-1}$	
5	$x^a e^{-bx}$	$\Gamma(a+1)(p+b)^{-a-1}$	$a>-1$
6	$\sinh(ax)$	$\dfrac{a}{p^2-a^2}$	
7	$\cosh(ax)$	$\dfrac{p}{p^2-a^2}$	
8	$\ln x$	$-\dfrac{1}{p}(\ln p+\mathcal{C})$	$\mathcal{C}=0.5772\ldots$ is the Euler constant
9	$\sin(ax)$	$\dfrac{a}{p^2+a^2}$	
10	$\cos(ax)$	$\dfrac{p}{p^2+a^2}$	
11	$\operatorname{erfc}\Big(\dfrac{a}{2\sqrt{x}}\Big)$	$\dfrac{1}{p}\exp\big(-a\sqrt{p}\big)$	$a\ge 0$
12	$J_0(ax)$	$\dfrac{1}{\sqrt{p^2+a^2}}$	$J_0(x)$ is the Bessel function

M10.2.3. Limit Theorems. Representation of Inverse Transforms as Convergent Series

▶ **Limit theorems.**

THEOREM 1. *Let* $0 \le x < \infty$ *and* $\widetilde{f}(p) = \mathfrak{L}\bigl\{f(x)\bigr\}$ *be the Laplace transform of* $f(x)$. *If a limit of* $f(x)$ *as* $x \to 0$ *exists, then*

$$\lim_{x\to 0} f(x) = \lim_{p\to\infty} \bigl[p\widetilde{f}(p)\bigr].$$

THEOREM 2. *If a limit of* $f(x)$ *as* $x \to \infty$ *exists, then*

$$\lim_{x\to \infty} f(x) = \lim_{p\to 0} \bigl[p\widetilde{f}(p)\bigr].$$

▶ **Representation of inverse transforms as convergent series.**

THEOREM 1. *Suppose the transform* $\widetilde{f}(p)$ *can be expanded into series in negative powers of* p,

$$\widetilde{f}(p) = \sum_{n=1}^{\infty} \frac{a_n}{p^n},$$

convergent for $|p| > R$, *where* R *is an arbitrary positive number; note that the transform tends to zero as* $|p| \to \infty$. *Then the inverse transform can be obtained by the formula*

$$f(x) = \sum_{n=1}^{\infty} \frac{a_n}{(n-1)!} x^{n-1},$$

where the series on the right-hand side is convergent for all x.

THEOREM 2. *Suppose the transform* $\widetilde{f}(p)$, $|p| > R$, *is represented by an absolutely convergent series,*

$$\widetilde{f}(p) = \sum_{n=0}^{\infty} \frac{a_n}{p^{\lambda_n}}, \qquad \text{(M10.2.3.1)}$$

where $\{\lambda_n\}$ *is any positive increasing sequence,* $0 < \lambda_0 < \lambda_1 < \cdots \to \infty$. *Then it is possible to proceed termwise from series (M10.2.3.1) to the following inverse transform series:*

$$f(x) = \sum_{n=0}^{\infty} \frac{a_n}{\Gamma(\lambda_n)} x^{\lambda_n - 1}, \qquad \text{(M10.2.3.2)}$$

where $\Gamma(\lambda)$ *is the Gamma function. Series (M10.2.3.2) is convergent for all real and complex values of* x *other than zero (if* $\lambda_0 \ge 1$, *the series is convergent for all* x*).*

M10.3. Various Forms of the Fourier Transform

M10.3.1. Fourier Transform and the Inverse Fourier Transform

▶ **Standard form of the Fourier transform.** The *Fourier transform* is defined as follows:

$$\widetilde{f}(u) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} f(x)\, e^{-iux}\, dx. \qquad \text{(M10.3.1.1)}$$

For brevity, we rewrite formula (M10.3.1.1) as follows:

$$\widetilde{f}(u) = \mathfrak{F}\{f(x)\} \qquad \text{or} \qquad \widetilde{f}(u) = \mathfrak{F}\{f(x), u\}.$$

Given $\widetilde{f}(u)$, the function $f(x)$ can be found by means of the *inverse Fourier transform*

$$f(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \widetilde{f}(u)\, e^{iux}\, du. \tag{M10.3.1.2}$$

Formula (M10.3.1.2) holds for continuous functions. If $f(x)$ has a (finite) jump discontinuity at a point $x = x_0$, then the right-hand side of (M10.3.1.2) evaluates to $\frac{1}{2}\big[f(x_0-0) + f(x_0+0)\big]$ at this point.

For brevity, we rewrite formula (M10.3.1.2) as follows:

$$f(x) = \mathfrak{F}^{-1}\{\widetilde{f}(u)\} \qquad \text{or} \qquad f(x) = \mathfrak{F}^{-1}\{\widetilde{f}(u),\, x\}.$$

► Convolution theorem. Main properties of the Fourier transform.

1°. The *convolution* of two functions $f(x)$ and $g(x)$ is defined as

$$f(x) * g(x) \equiv \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} f(x-t) g(t)\, dt.$$

By performing substitution $x - t = u$, we see that the convolution is symmetric with respect to the convolved functions: $f(x) * g(x) = g(x) * f(x)$.

The *convolution theorem* states that

$$\mathfrak{F}\big\{f(x) * g(x)\big\} = \mathfrak{F}\big\{f(x)\big\}\, \mathfrak{F}\big\{g(x)\big\}.$$

2°. The main properties of the correspondence between functions and their Fourier transforms are gathered in Table M10.3.

TABLE M10.3
Main properties of the Fourier transform.

No.	Function	Fourier transform	Operation
1	$af_1(x) + bf_2(x)$	$a\widetilde{f}_1(u) + b\widetilde{f}_2(u)$	Linearity
2	$f(x/a),\ a > 0$	$a\widetilde{f}(au)$	Scaling
3	$x^n f(x);\ n = 1, 2, \ldots$	$i^n \widetilde{f}_u^{(n)}(u)$	Differentiation of the transform
4	$f''_{xx}(x)$	$-u^2 \widetilde{f}(u)$	Differentiation
5	$f_x^{(n)}(x)$	$(iu)^n \widetilde{f}(u)$	Differentiation
6	$\int_{-\infty}^{\infty} f_1(\xi) f_2(x-\xi)\, d\xi$	$\widetilde{f}_1(u)\widetilde{f}_2(u)$	Convolution

M10.3.2. Fourier Cosine and Sine Transforms

► Fourier cosine transform.

1°. Let a function $f(x)$ be integrable on the semiaxis $0 \le x < \infty$. The *Fourier cosine transform* is defined by

$$\widetilde{f}_{\mathrm{c}}(u) = \sqrt{\frac{2}{\pi}} \int_0^\infty f(x) \cos(xu)\, dx, \qquad 0 < u < \infty. \tag{M10.3.2.1}$$

Given $\widetilde{f}_{\mathrm{c}}(u)$, the function $f(x)$ can be found by means of the *Fourier cosine inversion formula*

$$f(x) = \sqrt{\frac{2}{\pi}} \int_0^\infty \widetilde{f}_{\mathrm{c}}(u) \cos(xu)\, du, \qquad 0 < x < \infty. \tag{M10.3.2.2}$$

The Fourier cosine transform (M10.3.2.1) is denoted for brevity by $\widetilde{f}_{\mathrm{c}}(u) = \mathfrak{F}_{\mathrm{c}}\{f(x)\}$.

2°. Some other properties of the Fourier cosine transform:

$$\begin{aligned} \mathfrak{F}_{\mathrm{c}}\{x^{2n} f(x)\} &= (-1)^n \frac{d^{2n}}{du^{2n}} \mathfrak{F}_{\mathrm{c}}\{f(x)\}, \quad n = 1, 2, \dots; \\ \mathfrak{F}_{\mathrm{c}}\{f''(x)\} &= -u^2 \mathfrak{F}_{\mathrm{c}}\{f(x)\}. \end{aligned}$$

The function $f(x)$ here is assumed to vanish sufficiently rapidly (exponentially) as $x \to \infty$. In the latter formula, the condition $f'(0) = 0$ is assumed to hold.

Parseval's relation for the Fourier cosine transform:

$$\int_0^\infty \mathfrak{F}_{\mathrm{c}}\{f(x)\} \mathfrak{F}_{\mathrm{c}}\{g(x)\}\, du = \int_0^\infty f(x) g(x)\, dx.$$

There are tables of the Fourier cosine transform (see Section S2.3 and the references listed at the end of the current chapter).

► Fourier sine transform.

1°. Let a function $f(x)$ be integrable on the semiaxis $0 \le x < \infty$. The *Fourier sine transform* is defined by

$$\widetilde{f}_{\mathrm{s}}(u) = \sqrt{\frac{2}{\pi}} \int_0^\infty f(x) \sin(xu)\, dx, \qquad 0 < u < \infty. \tag{M10.3.2.3}$$

For given $\widetilde{f}_{\mathrm{s}}(u)$, the function $f(x)$ can be found by means of the *inverse Fourier sine transform*

$$f(x) = \sqrt{\frac{2}{\pi}} \int_0^\infty \widetilde{f}_{\mathrm{s}}(u) \sin(xu)\, du, \qquad 0 < x < \infty. \tag{M10.3.2.4}$$

The Fourier sine transform (M10.3.2.3) is briefly denoted by $\widetilde{f}_{\mathrm{s}}(u) = \mathfrak{F}_{\mathrm{s}}\{f(x)\}$.

2°. Some other properties of the Fourier sine transform:

$$\mathfrak{F}_\mathrm{s}\bigl\{x^{2n}f(x)\bigr\}=(-1)^n\frac{d^{2n}}{du^{2n}}\mathfrak{F}_\mathrm{s}\bigl\{f(x)\bigr\},\qquad n=1,\,2,\,\dots\,;$$
$$\mathfrak{F}_\mathrm{s}\bigl\{f''(x)\bigr\}=-u^2\mathfrak{F}_\mathrm{s}\bigl\{f(x)\bigr\}.$$

The function $f(x)$ here is assumed to vanish sufficiently rapidly (exponentially) as $x\to\infty$. In the latter formula, the condition $f(0)=0$ is assumed to hold.

Parseval's relation for the Fourier sine transform:

$$\int_0^\infty \mathfrak{F}_\mathrm{s}\bigl\{f(x)\bigr\}\mathfrak{F}_\mathrm{s}\bigl\{g(x)\bigr\}\,du=\int_0^\infty f(x)g(x)\,dx.$$

There are tables of the Fourier sine transform (see Section S2.4 and the references listed at the end of the current chapter).

M10.4. Mellin Transform and Other Transforms

M10.4.1. Mellin Transform and the Inversion Formula

► **Mellin transform.** Suppose that a function $f(x)$ is defined for positive x and satisfies the conditions

$$\int_0^1 |f(x)|\,x^{\sigma_1-1}\,dx<\infty,\qquad \int_1^\infty |f(x)|\,x^{\sigma_2-1}\,dx<\infty$$

for some real numbers σ_1 and σ_2, $\sigma_1<\sigma_2$.

The Mellin transform of $f(x)$ is defined by

$$\hat f(s)=\int_0^\infty f(x)x^{s-1}\,dx,\tag{M10.4.1.1}$$

where $s=\sigma+i\tau$ is a complex variable ($\sigma_1<\sigma<\sigma_2$).

For brevity, we rewrite formula (M10.4.1.1) as follows:

$$\hat f(s)=\mathfrak{M}\{f(x)\}\qquad\text{or}\qquad \hat f(s)=\mathfrak{M}\{f(x),s\}.$$

► **Inverse Mellin transform.** Given $\hat f(s)$, the function $f(x)$ can be found by means of the *inverse Mellin transform*

$$f(x)=\frac{1}{2\pi i}\int_{\sigma-i\infty}^{\sigma+i\infty}\hat f(s)x^{-s}\,ds\qquad(\sigma_1<\sigma<\sigma_2),\tag{M10.4.1.2}$$

where the integration path is parallel to the imaginary axis of the complex plane s and the integral is understood in the sense of the Cauchy principal value.

Formula (M10.4.1.2) holds for continuous functions. If $f(x)$ has a (finite) jump discontinuity at a point $x=x_0>0$, then the right-hand side of (M10.4.1.2) evaluates to $\frac12\bigl[f(x_0-0)+f(x_0+0)\bigr]$ at this point (for $x_0=0$, the first term in the square brackets must be omitted).

For brevity, we rewrite formula (M10.4.1.2) in the form

$$f(x)=\mathfrak{M}^{-1}\{\hat f(s)\}\qquad\text{or}\qquad f(x)=\mathfrak{M}^{-1}\{\hat f(s),\,x\}.$$

M10.4.2. Main Properties of the Mellin Transform. Relation Among the Mellin, Laplace, and Fourier Transforms

► **Main properties of the Mellin transform.** The main properties of the correspondence between the functions and their Mellin transforms are gathered in Table M10.4.

TABLE M10.4
Main properties of the Mellin transform.

No.	Function	Mellin transform	Operation
1	$af_1(x)+bf_2(x)$	$a\hat{f}_1(s)+b\hat{f}_2(s)$	Linearity
2	$f(ax),\ a>0$	$a^{-s}\hat{f}(s)$	Scaling
3	$x^a f(x)$	$\hat{f}(s+a)$	Shift of the argument of the transform
4	$f(x^2)$	$\frac{1}{2}\hat{f}\left(\frac{1}{2}s\right)$	Squared argument
5	$f(1/x)$	$\hat{f}(-s)$	Inversion of the argument of the transform
6	$x^\lambda f\left(ax^\beta\right),\ \ a>0, \beta\neq 0$	$\dfrac{1}{\beta}a^{-\frac{s+\lambda}{\beta}}\hat{f}\left(\dfrac{s+\lambda}{\beta}\right)$	Power law transform
7	$f'_x(x)$	$-(s-1)\hat{f}(s-1)$	Differentiation
8	$xf'_x(x)$	$-s\hat{f}(s)$	Differentiation
9	$f_x^{(n)}(x)$	$(-1)^n\dfrac{\Gamma(s)}{\Gamma(s-n)}\hat{f}(s-n)$	Multiple differentiation
10	$\left(x\dfrac{d}{dx}\right)^n f(x)$	$(-1)^n s^n\hat{f}(s)$	Multiple differentiation
11	$x^\alpha\displaystyle\int_0^\infty t^\beta f_1(xt)f_2(t)\,dt$	$\hat{f}_1(s+\alpha)\hat{f}_2(1-s-\alpha+\beta)$	Complicated integration
12	$x^\alpha\displaystyle\int_0^\infty t^\beta f_1\left(\dfrac{x}{t}\right)f_2(t)\,dt$	$\hat{f}_1(s+\alpha)\hat{f}_2(s+\alpha+\beta+1)$	Complicated integration

► **Relation among the Mellin, Laplace, and Fourier transforms.** There are tables of direct and inverse Mellin transforms (see the references listed at the end of the current chapter) that are useful in solving specific integral and differential equations. The Mellin transform is related to the Laplace and Fourier transforms by

$$\mathfrak{M}\{f(x),s\} = \mathfrak{L}\{f(e^x),-s\} + \mathfrak{L}\{f(e^{-x}),s\} = \mathfrak{F}\{f(e^x),is\},$$

which makes it possible to apply much more common tables of direct and inverse Laplace and Fourier transforms.

M10.4.3. Summary Table of Integral Transforms

Table M10.5 summarizes the integral transforms considered above and also lists some other integral transforms; for the constraints imposed on the functions and parameters occurring in the integrand, see the references given at the end of this section.

TABLE M10.5
Summary table of integral transforms.

Integral transform	Definition	Inversion formula
Laplace transform	$\widetilde{f}(p)=\int_0^\infty e^{-px}f(x)\,dx$	$f(x)=\dfrac{1}{2\pi i}\int_{c-i\infty}^{c+i\infty} e^{px}\widetilde{f}(p)\,dp$
Laplace–Carson transform	$\widetilde{f}(p)=p\int_0^\infty e^{-px}f(x)\,dx$	$f(x)=\dfrac{1}{2\pi i}\int_{c-i\infty}^{c+i\infty} e^{px}\dfrac{\widetilde{f}(p)}{p}\,dp$
Two-sided Laplace transform	$\widetilde{f}_*(p)=\int_{-\infty}^\infty e^{-px}f(x)\,dx$	$f(x)=\dfrac{1}{2\pi i}\int_{c-i\infty}^{c+i\infty} e^{px}\widetilde{f}_*(p)\,dp$
Fourier transform	$\widetilde{f}(u)=\dfrac{1}{\sqrt{2\pi}}\int_{-\infty}^\infty e^{-iux}f(x)\,dx$	$f(x)=\dfrac{1}{\sqrt{2\pi}}\int_{-\infty}^\infty e^{iux}\widetilde{f}(u)\,du$
Fourier sine transform	$\widetilde{f}_{\rm s}(u)=\sqrt{\dfrac{2}{\pi}}\int_0^\infty \sin(xu)f(x)\,dx$	$f(x)=\sqrt{\dfrac{2}{\pi}}\int_0^\infty \sin(xu)\widetilde{f}_{\rm s}(u)\,du$
Fourier cosine transform	$\widetilde{f}_{\rm c}(u)=\sqrt{\dfrac{2}{\pi}}\int_0^\infty \cos(xu)f(x)\,dx$	$f(x)=\sqrt{\dfrac{2}{\pi}}\int_0^\infty \cos(xu)\widetilde{f}_{\rm c}(u)\,du$
Hartley transform	$\widetilde{f}_{\rm h}(u)=\dfrac{1}{\sqrt{2\pi}}\int_{-\infty}^\infty (\cos xu+\sin xu)f(x)\,dx$	$f(x)=\dfrac{1}{\sqrt{2\pi}}\int_{-\infty}^\infty (\cos xu+\sin xu)\widetilde{f}_{\rm h}(u)\,du$
Mellin transform	$\widehat{f}(s)=\int_0^\infty x^{s-1}f(x)\,dx$	$f(x)=\dfrac{1}{2\pi i}\int_{c-i\infty}^{c+i\infty} x^{-s}\widehat{f}(s)\,ds$
Hankel transform	$\widehat{f}_\nu(w)=\int_0^\infty xJ_\nu(xw)f(x)\,dx$	$f(x)=\int_0^\infty wJ_\nu(xw)\widehat{f}_\nu(w)\,dw$
Y-transform	$F_\nu(u)=\int_0^\infty \sqrt{ux}\,Y_\nu(ux)f(x)\,dx$	$f(x)=\int_0^\infty \sqrt{ux}\,\mathbf{H}_\nu(ux)F_\nu(u)\,du$
Meijer transform (K-transform)	$\widehat{f}(s)=\sqrt{\dfrac{2}{\pi}}\int_0^\infty \sqrt{sx}\,K_\nu(sx)f(x)\,dx$	$f(x)=\dfrac{1}{i\sqrt{2\pi}}\int_{c-i\infty}^{c+i\infty} \sqrt{sx}\,I_\nu(sx)\widehat{f}(s)\,ds$
Kontorovich–Lebedev transform	$F(\tau)=\int_0^\infty K_{i\tau}(x)f(x)\,dx$	$f(x)=\dfrac{2}{\pi^2 x}\int_0^\infty \tau\sinh(\pi\tau)K_{i\tau}(x)F(\tau)\,d\tau$

NOTATION: $i=\sqrt{-1}$; $J_\mu(x)$ and $Y_\mu(x)$ are the Bessel functions of the first and the second kind, respectively; $I_\mu(x)$ and $K_\mu(x)$ are the modified Bessel functions of the first and the second kind, respectively; and $\mathbf{H}_\nu(x)=\sum_{j=0}^\infty \dfrac{(-1)^j(x/2)^{\nu+2j+1}}{\Gamma\bigl(j+\frac{3}{2}\bigr)\Gamma\bigl(\nu+j+\frac{3}{2}\bigr)}$ is the Struve function.

Chapter M11

Ordinary Differential Equations

M11.1. First-Order Differential Equations

M11.1.1. General Concepts. The Cauchy Problem. Uniqueness and Existence Theorems

► **Equations solved for the derivative. General solution.** A *first-order ordinary differential equation** solved for the derivative has the form

$$y'_x = f(x,y). \qquad \text{(M11.1.1.1)}$$

Sometimes it is represented in terms of differentials as $dy = f(x,y)\,dx$.

A *solution of a differential equation* is a function $y(x)$ that, when substituted into the equation, turns it into an identity. The *general solution of a differential equation* is the set of all its solutions. In some cases, the general solution can be represented as a function $y = \varphi(x,C)$ that depends on one *arbitrary constant* C; specific values of C define specific solutions of the equation (*particular solutions*). In practice, the general solution more frequently appears in implicit form, $\Phi(x,y,C) = 0$, or parametric form, $x = x(t,C)$, $y = y(t,C)$.

Geometrically, the general solution (also called the general integral) of an equation is a family of curves in the xy-plane depending on a single parameter C; these curves are called *integral curves* of the equation. To each particular solution (particular integral) there corresponds a single curve that passes through a given point (x_0,y_0) in the plane.

For each point (x,y), the equation $y'_x = f(x,y)$ defines a value of y'_x, i.e., the slope of the integral curve that passes through this point. In other words, the equation generates a field of directions in the xy-plane. From the geometrical point of view, the problem of solving a first-order differential equation involves finding the curves, the slopes of which at each point coincide with the direction of the field at this point.

Figure M11.1 depicts the tangent to an integral curve at a point (x_0,y_0); the slope of the integral curve at this point is determined by the right-hand side of equation (M11.1.1.1): $\tan\alpha = f(x_0,y_0)$. The little segments show the field of tangents to the integral curves of the differential equation (M11.1.1.1) at other points.

► **Equations integrable by quadrature.** The process of finding a solution to a differential equation is called integration of this equation. The problem of integration of equation (M11.1.1.1) can often be reduced to the problem of finding indefinite integrals, or quadratures. A solution is expressed as a quadrature if it expressed in terms of elementary functions and the functions appearing in the equation using a finite set of the arithmetic operations, function compositions, and indefinite integrals. An equation is said to be integrable by quadrature if its general solution can be expressed in terms of quadratures.

---

* In what follows, we often call an ordinary differential equation a “differential equation” or, even shorter, an “equation.”

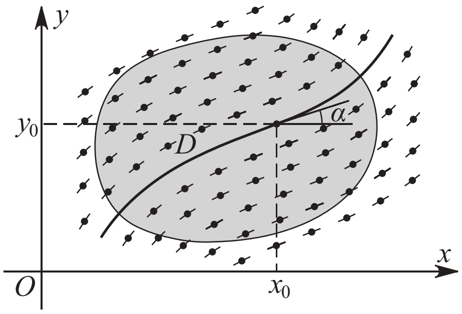

Figure M11.1. The direction field of a differential equation and the integral curve passing through a point (x_0, y_0).

► **Cauchy problem. The uniqueness and existence theorems.** The *Cauchy problem*: find a solution of equation (M11.1.1.1) that satisfies the *initial condition*

$$y = y_0 \quad \text{at} \quad x = x_0, \tag{M11.1.1.2}$$

where y_0 and x_0 are some numbers.

Geometrical meaning of the Cauchy problem: find an integral curve of equation (M11.1.1.1) that passes through the point (x_0, y_0); see Fig. M11.1.

Condition (M11.1.1.2) is alternatively written $y(x_0) = y_0$ or $y|_{x=x_0} = y_0$.

THEOREM (EXISTENCE, PEANO). *Let the function $f(x, y)$ be continuous in an open domain D of the xy-plane. Then there is at least one integral curve of equation (M11.1.1.1) that passes through a point $(x_0, y_0) \in D$; each of these curves can be extended at both ends up to the boundary of any closed domain $D_0 \subset D$ such that (x_0, y_0) belongs to the interior of D_0.*

THEOREM (UNIQUENESS). *Let the function $f(x, y)$ be continuous in an open domain D and have in D a bounded partial derivative with respect to y (or the Lipschitz condition holds: $|f(x, y) - f(x, z)| \le M|y - z|$, where M is some positive number and $(x, z) \in D$). Then there is a unique solution of equation (M11.1.1.1) satisfying condition (M11.1.1.2).*

► **Equations not solved for the derivative. The existence theorem.** A first-order differential equation not solved for the derivative can generally be written as

$$F(x, y, y'_x) = 0. \tag{M11.1.1.3}$$

THEOREM (EXISTENCE AND UNIQUENESS). *There exists a unique solution $y = y(x)$ of equation (M11.1.1.3) satisfying the conditions $y|_{x=x_0} = y_0$ and $y'_x|_{x=x_0} = t_0$, where t_0 is one of the real roots of the equation $F(x_0, y_0, t_0) = 0$ if the following conditions hold in a neighborhood of the point (x_0, y_0, t_0):*

1. *The function $F(x, y, t)$ is continuous in each of the three arguments.*
2. *The partial derivative F_t exists and is nonzero.*
3. *There is a bounded partial derivative with respect to y, $|F_y| \le M$.*

The solution surely exists if $|x - x_0| \le a$, where a is a (sufficiently small) positive number.

► **Singular solutions.** A point (x, y) at which the uniqueness of the solution to equation (M11.1.1.3) is violated is called a *singular* point. If conditions 1 and 3 of the existence and uniqueness theorem hold, then

$$F(x, y, t) = 0, \qquad F_t(x, y, t) = 0 \tag{M11.1.1.4}$$

simultaneously at each singular point. Relations (M11.1.1.4) define a *t-discriminant curve* in parametric form. In some cases, the parameter t can be eliminated from (M11.1.1.4) to give an equation of this curve in implicit form, $\Psi(x, y) = 0$. If a branch $y = \psi(x)$ of the curve $\Psi(x, y) = 0$ consists of singular points and, at the same time, is an integral curve, then this branch is called a *singular integral curve* and the function $y = \psi(x)$ is a *singular solution* of equation (M11.1.1.3).

The singular solutions can be obtained by finding the *envelope of the family of integral curves*, $\Phi(x, y, C) = 0$, of equation (M11.1.1.3). The envelope is part of the *C-discriminant curve*, which is defined by the equations

$$\Phi(x, y, C) = 0, \qquad \Phi_C(x, y, C) = 0.$$

The branch of the C-discriminant curve at which

(a) there exist bounded partial derivatives, $|\Phi_x| < M_1$ and $|\Phi_y| < M_2$, and
(b) $|\Phi_x| + |\Phi_y| \neq 0$

is the envelope.

M11.1.2. Equations Solved for the Derivative. Simplest Techniques of Integration

► Equations with separated or separable variables.

1°. An *equation with separated variables* (a *separated equation*) has the form

$$f(y)y'_x = g(x).$$

Equivalently, the equation can be rewritten as $f(y)\,dy = g(x)\,dx$ (the right-hand side depends on x alone and the left-hand side on y alone). The general solution can be obtained by integration:

$$\int f(y)\,dy = \int g(x)\,dx + C,$$

where C is an arbitrary constant.

2°. An *equation with separable variables* (a *separable equation*) is generally represented by

$$f_1(y)g_1(x)y'_x = f_2(y)g_2(x).$$

Dividing the equation by $f_2(y)g_1(x)$, one obtains a separated equation. Integrating yields

$$\int \frac{f_1(y)}{f_2(y)}\,dy = \int \frac{g_2(x)}{g_1(x)}\,dx + C.$$

Remark. Solutions corresponding to $f_2(y) = 0$ may be lost when dividing the equation by $f_2(y)g_1(x)$. Therefore, the case of $f_2(y) = 0$, should be treated separately.

Many ordinary differential equations are reduced to separable equations.

Example. The equation

$$y'_x = yf(e^{\lambda x}y^k)$$

can be reduced, with the substitution $z = e^{\lambda x}y^k$, to a separable equation: $z'_x = \lambda z + kzf(z)$.

Some other equations reducible to separable equations are considered below.

► **Equation of the form $y'_x = f(ax + by)$.** For $b = 0$, it is an equation with separated variables. For $b \neq 0$, the substitution $z = ax + by$ brings the equation to a separable equation, $z'_x = bf(z) + a$.

► **Homogeneous equation.** A *homogeneous equation* remains the same under simultaneous scaling (dilation) of the independent and dependent variables in accordance with the rule $x \to \alpha x$, $y \to \alpha y$, where α is an arbitrary constant ($\alpha \neq 0$). Such equations can be represented in the form

$$y'_x = f\left(\frac{y}{x}\right).$$

The substitution $u = y/x$ brings a homogeneous equation to a separable one, $xu'_x = f(u) - u$.

Remark. The equations of the form

$$y'_x = f\left(\frac{a_1x + b_1y + c_1}{a_2x + b_2y + c_2}\right)$$

can be reduced to a homogeneous equation. To this end, for $a_1x + b_1y \neq k(a_2x + b_2y)$, one should use the change of variables $\xi = x - x_0$, $\eta = y - y_0$, where the constants x_0 and y_0 are determined by solving the linear algebraic system

$$a_1x_0 + b_1y_0 + c_1 = 0,$$
$$a_2x_0 + b_2y_0 + c_2 = 0.$$

As a result, one arrives at the following equation for $\eta = \eta(\xi)$:

$$\eta'_\xi = f\left(\frac{a_1\xi + b_1\eta}{a_2\xi + b_2\eta}\right).$$

On dividing the numerator and denominator of the argument of f by ξ, one obtains a homogeneous equation whose right-hand side is dependent on the ratio η/ξ only:

$$\eta'_\xi = f\left(\frac{a_1 + b_1\eta/\xi}{a_2 + b_2\eta/\xi}\right).$$

► **Generalized homogeneous equation.**

1°. A *generalized homogeneous equation* remains the same under simultaneous scaling of the independent and dependent variables in accordance with the rule $x \to \alpha x$, $y \to \alpha^k y$, where $\alpha \neq 0$ is an arbitrary constant and k is some number. Such equations can be represented in the form

$$y'_x = x^{k-1} f(yx^{-k}).$$

The substitution $u = yx^{-k}$ brings a generalized homogeneous equation to a separable equation, $xu'_x = f(u) - ku$.

Example. Consider the equation

$$y'_x = ax^2y^4 + by^2. \qquad \text{(M11.1.2.1)}$$

Let us perform the transformation $x = \alpha\bar{x}$, $y = \alpha^k\bar{y}$ and then multiply the resulting equation by α^{1-k} to obtain

$$\bar{y}'_{\bar{x}} = a\alpha^{3(k+1)}\bar{x}^2\bar{y}^4 + b\alpha^{k+1}\bar{y}^2. \qquad \text{(M11.1.2.2)}$$

It is apparent that if $k = -1$, the transformed equation (M11.1.2.2) is the same as the original one, up to notation. This means that equation (M11.1.2.1) is generalized homogeneous of degree $k = -1$. Therefore, the substitution $u = xy$ brings it to a separable equation: $xu'_x = au^4 + bu^2 + u$.

2°. Alternatively, a generalized homogeneous equation can be represented as

$$y'_x = \frac{y}{x} f(x^n y^m).$$

The substitution $z = x^n y^m$ leads to a separable equation: $xz'_x = nz + mzf(z)$.

► **Linear equation.** A first-order *linear equation* is written as

$$y'_x + f(x)y = g(x). \tag{M11.1.2.3}$$

The solution is sought in the product form $y = uv$, where $v = v(x)$ is any function that satisfies the "truncated" equation $v'_x + f(x)v = 0$ [as $v(x)$ one takes the particular solution $v = e^{-F}$, where $F = \int f(x)\,dx$]. As a result, one obtains the following separable equation for $u = u(x)$: $v(x)u'_x = g(x)$. Integrating it yields the general solution:

$$y(x) = e^{-F}\Big(\int e^F g(x)\,dx + C\Big), \qquad F = \int f(x)\,dx,$$

where C is an arbitrary constant.

► **Bernoulli equation.** A *Bernoulli equation* has the form

$$y'_x + f(x)y = g(x)y^a, \qquad a \neq 0,\ 1. \tag{M11.1.2.4}$$

(For $a = 0$ and $a = 1$, it is a linear equation; see above.) The substitution $z = y^{1-a}$ brings it to a linear equation, $z'_x + (1-a)f(x)z = (1-a)g(x)$. With this in view, one can obtain the general integral:

$$y^{1-a} = Ce^{-F} + (1-a)e^{-F}\int e^F g(x)\,dx, \qquad \text{where} \quad F = (1-a)\int f(x)\,dx.$$

► **Equation with exponential nonlinearity reducible to a linear equation.** Consider the equation

$$y'_x = f(x)e^{\lambda y} + g(x).$$

The substitution $u = e^{-\lambda y}$ leads to a linear equation: $u'_x = -\lambda g(x)u - \lambda f(x)$.

M11.1.3. Exact Differential Equations. Integrating Factor

► **Exact differential equations.** An *exact differential equation* has the form

$$f(x,y)\,dx + g(x,y)\,dy = 0, \quad \text{where} \quad \frac{\partial f}{\partial y} = \frac{\partial g}{\partial x}. \tag{M11.1.3.1}$$

The left-hand side of the equation is the total differential of a function of two variables $U(x,y)$. In this case, the general integral is given by

$$U(x,y) = C,$$

where C is an arbitrary constant and the function U is determined from the system

$$\frac{\partial U}{\partial x} = f, \quad \frac{\partial U}{\partial y} = g.$$

Integrating the first equation yields $U = \int f(x,y)\,dx + \Psi(y)$ (while integrating, the variable y is treated as a parameter). On substituting this expression into the second equation, one identifies the function Ψ (and hence, U). As a result, the general integral of an exact differential equation can be represented in the form

$$\int_{x_0}^{x} f(\xi,y)\,d\xi + \int_{y_0}^{y} g(x_0,\eta)\,d\eta = C, \tag{M11.1.3.2}$$

where x_0 and y_0 are any numbers (from the domain of definition of the equation).

TABLE M11.1
An integrating factor $\mu = \mu(x, y)$ for some types of ordinary differential equations $f\,dx + g\,dy = 0$, where $f = f(x, y)$ and $g = g(x, y)$. The subscripts x and y indicate the corresponding partial derivatives.

No.	Conditions for f and g	Integrating factor	Remarks
1	$f = y\varphi(xy),\ g = x\psi(xy)$	$\mu = \frac{1}{xf-yg}$	$xf - yg \not\equiv 0$; $\varphi(z)$ and $\psi(z)$ are any functions
2	$f_x = g_y,\ f_y = -g_x$	$\mu = \frac{1}{f^2+g^2}$	$f + ig$ is an analytic function of the complex variable $x + iy$
3	$\frac{f_y-g_x}{g} = \varphi(x)$	$\mu = \exp\bigl[\int \varphi(x)\,dx\bigr]$	$\varphi(x)$ is any function
4	$\frac{f_y-g_x}{f} = \varphi(y)$	$\mu = \exp\bigl[-\int \varphi(y)\,dy\bigr]$	$\varphi(y)$ is any function
5	$\frac{f_y-g_x}{g-f} = \varphi(x+y)$	$\mu = \exp\bigl[\int \varphi(z)\,dz\bigr],\ \ z = x+y$	$\varphi(z)$ is any function
6	$\frac{f_y-g_x}{yg-xf} = \varphi(xy)$	$\mu = \exp\bigl[\int \varphi(z)\,dz\bigr],\ \ z = xy$	$\varphi(z)$ is any function
7	$\frac{x^2(f_y-g_x)}{yg+xf} = \varphi\bigl(\frac{y}{x}\bigr)$	$\mu = \exp\bigl[-\int \varphi(z)\,dz\bigr],\ \ z = \frac{y}{x}$	$\varphi(z)$ is any function
8	$\frac{f_y-g_x}{xg-yf} = \varphi(x^2+y^2)$	$\mu = \exp\bigl[\frac{1}{2}\int \varphi(z)\,dz\bigr],\ z = x^2+y^2$	$\varphi(z)$ is any function
9	$f_y - g_x = \varphi(x)g - \psi(y)f$	$\mu = \exp\bigl[\int \varphi(x)\,dx + \int \psi(y)\,dy\bigr]$	$\varphi(x)$ and $\psi(y)$ are any functions

Example. Consider the equation

$$(ay^n + bx)y'_x + by + cx^m = 0, \qquad \text{or} \qquad (by + cx^m)\,dx + (ay^n + bx)\,dy = 0,$$

defined by the functions $f(x, y) = by + cx^m$ and $g(x, y) = ay^n + bx$. Computing the derivatives, we have

$$\frac{\partial f}{\partial y} = b, \qquad \frac{\partial g}{\partial x} = b \quad \Longrightarrow \quad \frac{\partial f}{\partial y} = \frac{\partial g}{\partial x}.$$

Hence the given equation is an exact differential equation. Its solution can be found using formula (M11.1.3.2) with $x_0 = y_0 = 0$:

$$\frac{a}{n+1}y^{n+1} + bxy + \frac{c}{m+1}x^{m+1} = C.$$

► **Integrating factor.** An *integrating factor* for the equation

$$f(x, y)\,dx + g(x, y)\,dy = 0$$

is a function $\mu(x, y) \not\equiv 0$ such that the left-hand side of the equation, when multiplied by $\mu(x, y)$, becomes a total differential, and the equation itself becomes an exact differential equation.

An integrating factor satisfies the first-order partial differential equation,

$$g\frac{\partial \mu}{\partial x} - f\frac{\partial \mu}{\partial y} = \left(\frac{\partial f}{\partial y} - \frac{\partial g}{\partial x}\right)\mu,$$

which is not generally easier to solve than the original equation.

Table M11.1 lists some special cases where an integrating factor can be found in explicit form.

M11.1.4. Riccati Equation

► **General Riccati equation.** A *Riccati equation* has the general form

$$y'_x = f_2(x)y^2 + f_1(x)y + f_0(x). \qquad \text{(M11.1.4.1)}$$

If $f_2 \equiv 0$, we have a linear equation, and if $f_0 \equiv 0$, we have a Bernoulli equation (see equation (M11.1.2.4) for $a = 2$), whose solutions were given previously. For arbitrary f_2, f_1, and f_0, the Riccati equation is not integrable by quadrature.

► **Use of particular solutions to construct the general solution.**

1°. Given a particular solution $y_0 = y_0(x)$ of the Riccati equation (M11.1.4.1), the general solution can be written as

$$y = y_0(x) + \Phi(x)\Big[C - \int \Phi(x) f_2(x)\,dx\Big]^{-1}, \qquad \text{(M11.1.4.2)}$$

where C is an arbitrary constant and

$$\Phi(x) = \exp\Big\{\int \big[2f_2(x)y_0(x) + f_1(x)\big]\,dx\Big\}. \qquad \text{(M11.1.4.3)}$$

To the particular solution $y_0(x)$ there corresponds $C = \infty$.

2°. Let $y_1 = y_1(x)$ and $y_2 = y_2(x)$ be two different particular solutions of equation (M11.1.4.1). Then the general solution can be expressed as

$$y = \frac{Cy_1 + U(x)y_2}{C + U(x)}, \quad \text{where} \quad U(x) = \exp\Big[\int f_2(y_1 - y_2)\,dx\Big].$$

To the particular solution $y_1(x)$, there corresponds $C = \infty$; and to $y_2(x)$, there corresponds $C = 0$.

3°. Let $y_1 = y_1(x)$, $y_2 = y_2(x)$, and $y_3 = y_3(x)$ be three distinct particular solutions of equation (M11.1.4.1). Then the general solution can be found without quadrature:

$$\frac{y - y_2}{y - y_1}\,\frac{y_3 - y_1}{y_3 - y_2} = C.$$

► **Some transformations.**

1°. The transformation (φ, ψ_1, ψ_2, ψ_3, and ψ_4 are arbitrary functions)

$$x = \varphi(\xi), \qquad y = \frac{\psi_4(\xi)u + \psi_3(\xi)}{\psi_2(\xi)u + \psi_1(\xi)}$$

reduces the Riccati equation (M11.1.4.1) to a Riccati equation for $u = u(\xi)$.

2°. Let $y_0 = y_0(x)$ be a particular solution of equation (M11.1.4.1). Then the substitution $y = y_0 + 1/w$ leads to a first-order linear equation for $w = w(x)$:

$$w'_x + \big[2f_2(x)y_0(x) + f_1(x)\big]w + f_2(x) = 0.$$

For solution of linear equations, see Subsection M11.1.2.

► **Reduction of the Riccati equation to a second-order linear equation.** The substitution

$$u(x) = \exp\Big(-\int f_2 y\,dx\Big)$$

reduces the general Riccati equation (M11.1.4.1) to a second-order linear equation:

$$f_2 u''_{xx} - \big[(f_2)'_x + f_1 f_2\big]u'_x + f_0 f_2^2 u = 0,$$

which often may be easier to solve than the original Riccati equation.

M11.1.5. Equations Not Solved for the Derivative

► **Method of "integration by differentiation."** In the general case, a first-order equation not solved for the derivative,

$$F(x,y,y'_x)=0, \tag{M11.1.5.1}$$

can be rewritten in the equivalent form

$$F(x,y,t)=0, \qquad t=y'_x. \tag{M11.1.5.2}$$

We look for a solution in parametric form: $x=x(t)$, $y=y(t)$. In accordance with the first relation in (M11.1.5.2), the differential of F is given by

$$F_x\,dx+F_y\,dy+F_t\,dt=0. \tag{M11.1.5.3}$$

Using the relation $dy=t\,dx$, we eliminate successively dy and dx from (M11.1.5.3). As a result, we obtain the system of two first-order ordinary differential equations:

$$\frac{dx}{dt}=-\frac{F_t}{F_x+tF_y},\qquad \frac{dy}{dt}=-\frac{tF_t}{F_x+tF_y}. \tag{M11.1.5.4}$$

By finding a solution of this system, one thereby obtains a solution of the original equation (M11.1.5.1) in parametric form, $x=x(t)$, $y=y(t)$.

Remark 1. The application of the above method may lead to loss of individual solutions (satisfying the condition $F_x+tF_y=0$); this issue requires further investigation.

Remark 2. One of the differential equations of system (M11.1.5.4) can be replaced by the algebraic equation $F(x,y,t)=0$; see equation (M11.1.5.2). This technique is used further for solving some equations.

► **Equations of the form $y=f(y'_x)$.** This equation is a special case of equation (M11.1.5.1), with $F(x,y,t)=y-f(t)$. The method of "integration by differentiation" yields

$$\frac{dx}{dt}=\frac{f'(t)}{t},\qquad y=f(t). \tag{M11.1.5.5}$$

Note the original equation is used here instead of the second equation in system (M11.1.5.4); this is convenient because the first equation in (M11.1.5.4) does not depend on y explicitly.

Integrating the first equation in (M11.1.5.5) yields the solution in parametric form,

$$x=\int\frac{f'(t)}{t}\,dt+C,\qquad y=f(t).$$

► **Equations of the form $x=f(y'_x)$.** This equation is a special case of equation (M11.1.5.1), with $F(x,y,t)=x-f(t)$. The method of "integration by differentiation" yields

$$x=f(t),\qquad \frac{dy}{dt}=tf'(t). \tag{M11.1.5.6}$$

Note the original equation is used here instead of the first equation in system (M11.1.5.4); this is convenient because the second equation in (M11.1.5.4) does not depend on x explicitly.

Integrating the second equation in (M11.1.5.6) yields the solution in parametric form,

$$x=f(t),\qquad y=\int tf'(t)\,dt+C.$$

► **Clairaut's equation $y = xy'_x + f(y'_x)$.** *Clairaut's equation* is a special case of equation (M11.1.5.1), with $F(x, y, t) = y - xt - f(t)$. It can be rewritten as

$$y = xt + f(t), \qquad t = y'_x. \tag{M11.1.5.7}$$

This equation corresponds to the degenerate case $F_x + tF_y \equiv 0$, where system (M11.1.5.4) cannot be obtained. One should proceed in the following way: the first relation in (M11.1.5.7) gives $dy = x\,dt + t\,dx + f'(t)\,dt$; performing the substitution $dy = t\,dx$, which follows from the second relation in (M11.1.5.7), one obtains

$$[x + f'(t)]\,dt = 0.$$

This equation splits into $dt = 0$ and $x + f'(t) = 0$. The solution of the first equation is obvious: $t = C$; it gives the general solution of Clairaut's equation,

$$y = Cx + f(C), \tag{M11.1.5.8}$$

which is a family of straight lines. The second equation generates a solution in parametric form,

$$x = -f'(t), \qquad y = -tf'(t) + f(t), \tag{M11.1.5.9}$$

which is a singular solution and is the envelope of the family of lines (M11.1.5.8).

Remark. There are also "compound" solutions of Clairaut's equation; they consist of part of the curve (M11.1.5.9) joined with the tangents at finite points; these tangents are defined by formula (M11.1.5.8).

► **Lagrange's equation $y = xf(y'_x) + g(y'_x)$.** *Lagrange's equation* is a special case of equation (M11.1.5.1), with $F(x, y, t) = y - xf(t) - g(t)$. In the special case $f(t) \equiv t$, it coincides with Clairaut's equation.

The method of "integration by differentiation" yields

$$\frac{dx}{dt} + \frac{f'(t)}{f(t) - t}x = \frac{g'(t)}{t - f(t)}, \qquad y = xf(t) + g(t). \tag{M11.1.5.10}$$

Here, the original equation is used instead of the second equation in system (M11.1.5.4); this is convenient because the first equation in (M11.1.5.4) does not depend on y explicitly.

The first equation of system (M11.1.5.10) is linear and can easily be integrated to obtain a solution to Lagrange's equation in parametric form.

Remark. With the above method, solutions of the form $y = t_k x + g(t_k)$, where the t_k are roots of the equation $f(t) - t = 0$, may be lost. These solutions can be particular or singular solutions of Lagrange's equation.

M11.1.6. Approximate Analytic Methods for Solution of Equations

► **Method of successive approximations (Picard's method).** The method of successive approximations consists of two stages. At the first stage, the Cauchy problem

$$y'_x = f(x, y) \qquad \text{(equation)}, \tag{M11.1.6.1}$$

$$y(x_0) = y_0 \qquad \text{(initial condition)} \tag{M11.1.6.2}$$

is reduced to the equivalent integral equation:

$$y(x) = y_0 + \int_{x_0}^{x} f(t, y(t))\,dt. \tag{M11.1.6.3}$$

Then a solution of equation (M11.1.6.3) is sought using the formula of successive approximations:

$$y_{n+1}(x) = y_0 + \int_{x_0}^{x} f(t, y_n(t))\,dt; \qquad n = 0,\ 1,\ 2,\ \ldots$$

The initial approximation $y_0(x)$ can be chosen arbitrarily; the simplest way is to take $y_0(x) = y_0$. The iterative process converges as $n \to \infty$, provided the conditions of the theorems in Subsection M11.1.1 are satisfied.

► **Method of Taylor series expansion in the independent variable.** A solution of the Cauchy problem (M11.1.6.1)–(M11.1.6.2) can be sought in the form of the Taylor series in powers of $(x - x_0)$:

$$y(x) = y(x_0) + y'_x(x_0)(x - x_0) + \frac{y''_{xx}(x_0)}{2!}(x - x_0)^2 + \cdots . \qquad \text{(M11.1.6.4)}$$

The first term $y(x_0)$ in solution (M11.1.6.4) is prescribed by the initial condition (M11.1.6.2). The values of the derivatives of $y(x)$ at $x = x_0$ are determined from equation (M11.1.6.1) and its derivative equations (obtained by successive differentiation), taking into account the initial condition (M11.1.6.2). In particular, setting $x = x_0$ in (M11.1.6.1) and substituting (M11.1.6.2), one obtains the value of the first derivative:

$$y'_x(x_0) = f(x_0, y_0). \qquad \text{(M11.1.6.5)}$$

Further, differentiating equation (M11.1.6.1) yields

$$y''_{xx} = f_x(x, y) + f_y(x, y)y'_x. \qquad \text{(M11.1.6.6)}$$

On substituting $x = x_0$, as well as the initial condition (M11.1.6.2) and the first derivative (M11.1.6.5), into the right-hand side of this equation, one calculates the value of the second derivative:

$$y''_{xx}(x_0) = f_x(x_0, y_0) + f(x_0, y_0)f_y(x_0, y_0).$$

Likewise, one can determine the subsequent derivatives of y at $x = x_0$.

Solution (M11.1.6.4) obtained by this method can normally be used in only some sufficiently small neighborhood of the point $x = x_0$.

Example. Consider the Cauchy problem for the equation

$$y'_x = e^y + \cos x$$

with the initial condition $y(0) = 0$.

Since $x_0 = 0$, we will be constructing a series in powers of x. It follows from the equation that $y'_x(0) = e^0 + \cos 0 = 2$. Differentiating the original equation yields $y''_{xx} = e^y y'_x - \sin x$. Using the initial condition and the condition $y'_x(0) = 2$ just obtained, we have $y''_{xx}(0) = e^0 \times 2 - \sin 0 = 2$. Similarly, we find that $y'''_{xxx} = e^y y''_{xx} + e^y (y'_x)^2 - \cos x$, whence $y'''_{xxx}(0) = e^0 \times 2 + e^0 \times 2^2 - \cos 0 = 5$.

Substituting the values of the derivatives at $x = 0$ into series (M11.1.6.4), we obtain the desired series representation of the solution: $y = 2x + x^2 + \frac{5}{6}x^3 + \cdots$.

M11.1.7. Numerical Integration of Differential Equations

► **Method of Euler polygonal lines.** Consider the Cauchy problem for the first-order differential equation

$$y'_x = f(x, y)$$

with the initial condition $y(x_0) = y_0$. Our aim is to construct an approximate solution $y = y(x)$ of this equation on an interval $[x_0, x_*]$.

Let us split the interval $[x_0, x_*]$ into n equal segments of length $\Delta x = \dfrac{x_* - x_0}{n}$. We seek approximate values y_1, y_2, …, y_n of the solution $y(x)$ at the partition points x_1, x_2, …, $x_n = x_*$.

For a given initial value $y_0 = y(x_0)$ and a sufficiently small Δx, the values of the unknown function $y_k = y(x_k)$ at the other points $x_k = x_0 + k\Delta x$ are calculated successively by the formula

$$y_{k+1} = y_k + f(x_k, y_k)\Delta x \qquad (\textit{Euler polygonal line}),$$

where $k = 0, 1, \ldots, n - 1$. The Euler method is a single-step method of the first-order approximation (with respect to the step Δx).

► **Single-step methods of the second-order approximation.** Two single-step methods for solving the Cauchy problem in the second-order approximation are specified by the recurrence formulas

$$y_{k+1} = y_k + f\bigl(x_k + \tfrac{1}{2}\Delta x,\ y_k + \tfrac{1}{2} f_k \Delta x)\Delta x \quad \text{(first method)},$$
$$y_{k+1} = y_k + \tfrac{1}{2}\bigl[f_k + f(x_{k+1},\ y_k + f_k\Delta x)\bigr]\Delta x \quad \text{(second method)},$$

where $f_k = f(x_k, y_k)$; $k = 0,\ 1,\ \dots,\ n-1$.

► **Runge–Kutta method of the fourth-order approximation.** This is one of the widely used methods. The unknown values y_k are successively found by the formulas

$$y_{k+1} = y_k + \tfrac{1}{6}(f_1 + 2f_2 + 2f_3 + f_4)\Delta x,$$

where

$$f_1 = f(x_k,\ y_k), \qquad f_2 = f(x_k + \tfrac{1}{2}\Delta x,\ y_k + \tfrac{1}{2} f_1\Delta x),$$
$$f_3 = f(x_k + \tfrac{1}{2}\Delta x,\ y_k + \tfrac{1}{2} f_2\Delta x), \qquad f_4 = f(x_k + \Delta x,\ y_k + f_3\Delta x).$$

Remark 1. All methods described in Subsection M11.1.7 are special cases of the Runge–Kutta method (a detailed description of this method can be found in the monographs listed at the end of the current chapter).

Remark 2. In practice, calculations are performed on the basis of any of the above recurrence formulas with two different steps Δx, $\frac{1}{2}\Delta x$ and an arbitrarily chosen small Δx. Then one compares the results obtained at common points. If these results coincide within the given order of accuracy, one assumes that the chosen step Δx ensures the desired accuracy of calculations. Otherwise, the step is halved and the calculations are performed with the steps $\frac{1}{2}\Delta x$ and $\frac{1}{4}\Delta x$, after which the results are compared again, etc. (Quite often, one compares the results of calculations with steps varying by a factor of ten or more.)

M11.2. Second-Order Linear Differential Equations

M11.2.1. Formulas for the General Solution. Some Transformations

► **Homogeneous linear equations. Formulas for the general solution.**

1°. Consider a second-order homogeneous linear equation in the general form

$$f_2(x)y''_{xx} + f_1(x)y'_x + f_0(x)y = 0. \tag{M11.2.1.1}$$

The *trivial solution*, $y = 0$, is a particular solution of the homogeneous linear equation.

Let $y_1(x)$, $y_2(x)$ be a fundamental system of solutions (nontrivial linearly independent particular solutions) of equation (M11.2.1.1). Then the general solution is given by

$$y = C_1 y_1(x) + C_2 y_2(x), \tag{M11.2.1.2}$$

where C_1 and C_2 are arbitrary constants.

2°. Let $y_1 = y_1(x)$ be any nontrivial particular solution of equation (M11.2.1.1). Then its general solution can be represented as

$$y = y_1\left(C_1 + C_2\int \frac{e^{-F}}{y_1^2}\,dx\right), \qquad \text{where} \quad F = \int \frac{f_1}{f_2}\,dx. \tag{M11.2.1.3}$$

► **Wronskian determinant and Liouville's formula.** The *Wronskian determinant* (or *Wronskian*) is defined by

$$W(x) = \begin{vmatrix} y_1(x) & y_2(x) \\ y_1'(x) & y_2'(x) \end{vmatrix} \equiv y_1(y_2)'_x - y_2(y_1)'_x,$$

where $y_1(x)$, $y_2(x)$ is a fundamental system of solutions of equation (M11.2.1.1).

Liouville's formula:

$$W(x) = W(x_0)\exp\left[-\int_{x_0}^{x} \frac{f_1(t)}{f_2(t)}\,dt\right].$$

► Simplest second-order linear equations and their solutions.

1°. The *second-order linear equation with constant coefficients*

$$y''_{xx} + ay'_x + by = 0 \qquad \text{(M11.2.1.4)}$$

has the following fundamental system of solutions:

$$\begin{array}{lll}
y_1(x) = \exp\bigl(-\tfrac{1}{2}ax\bigr)\sinh\bigl(\tfrac{1}{2}x\sqrt{a^2-4b}\,\bigr), & y_2(x) = \exp\bigl(-\tfrac{1}{2}ax\bigr)\cosh\bigl(\tfrac{1}{2}x\sqrt{a^2-4b}\,\bigr) & \text{if } a^2 > 4b;\\
y_1(x) = \exp\bigl(-\tfrac{1}{2}ax\bigr)\sin\bigl(\tfrac{1}{2}x\sqrt{4b-a^2}\,\bigr), & y_2(x) = \exp\bigl(-\tfrac{1}{2}ax\bigr)\cos\bigl(\tfrac{1}{2}x\sqrt{4b-a^2}\,\bigr) & \text{if } a^2 < 4b;\\
y_1(x) = \exp\bigl(-\tfrac{1}{2}ax\bigr), & y_2(x) = x\exp\bigl(-\tfrac{1}{2}ax\bigr) & \text{if } a^2 = 4b.
\end{array}$$

Remark. In physics equation (M11.2.1.4) is often called an *equation of damped oscillations.*

2°. The *Euler equation*

$$x^2y''_{xx} + axy'_x + by = 0 \qquad \text{(M11.2.1.5)}$$

is reduced by the change of variable $x = ke^t$ ($k \neq 0$) to the second-order linear equation with constant coefficients $y''_{tt} + (a-1)y'_t + by = 0$, which is treated in Item 1°.

Equation (M11.2.1.5) has the following fundamental system of solutions:

$$\begin{array}{lll}
y_1(x) = |x|^{\frac{1-a}{2}+\mu}, & y_2(x) = |x|^{\frac{1-a}{2}-\mu} & \text{if } (1-a)^2 > 4b,\\
y_1(x) = |x|^{\frac{1-a}{2}}, & y_2(x) = |x|^{\frac{1-a}{2}}\ln|x| & \text{if } (1-a)^2 = 4b,\\
y_1(x) = |x|^{\frac{1-a}{2}}\sin(\mu\ln|x|), & y_2(x) = |x|^{\frac{1-a}{2}}\cos(\mu\ln|x|) & \text{if } (1-a)^2 < 4b,
\end{array}$$

where $\mu = \frac{1}{2}|(1-a)^2 - 4b|^{1/2}$.

► Bessel equation and related equations.

1°. The *Bessel equation* has the form

$$x^2y''_{xx} + xy'_x + (x^2-\nu^2)y = 0.$$

It often arises in numerous applications.

Let ν be an arbitrary noninteger. Then the general solution of the Bessel equation is given by

$$y = C_1J_\nu(x) + C_2Y_\nu(x),$$

where $J_\nu(x)$ and $Y_\nu(x)$ are the *Bessel functions* of the first and second kind:

$$J_\nu(x) = \sum_{k=0}^{\infty}\frac{(-1)^k(x/2)^{2k+\nu}}{k!\,\Gamma(\nu+k+1)}, \qquad Y_\nu(x) = \frac{J_\nu(x)\cos\pi\nu - J_{-\nu}(x)}{\sin\pi\nu}.$$

In the case $\nu = n + \frac{1}{2}$, where $n = 0, 1, 2, \ldots$, the Bessel functions are expressed in terms of elementary functions:

$$J_{n+\frac{1}{2}}(x) = \sqrt{\frac{2}{\pi}}\,x^{n+\frac{1}{2}}\Bigl(-\frac{1}{x}\frac{d}{dx}\Bigr)^n\frac{\sin x}{x}, \qquad J_{-n-\frac{1}{2}}(x) = \sqrt{\frac{2}{\pi}}\,x^{n+\frac{1}{2}}\Bigl(\frac{1}{x}\frac{d}{dx}\Bigr)^n\frac{\cos x}{x},$$
$$Y_{n+\frac{1}{2}}(x) = (-1)^{n+1}J_{-n-\frac{1}{2}}(x).$$

The Bessel functions are described in Section M13.6 in detail.

TABLE M11.2
Some second-order linear equations whose solutions are expressed in terms of Bessel functions and modified Bessel functions.

Equation	General solution	Remarks
$y''_{xx} - ax^k y = 0$	$y = C_1\sqrt{x}\, J_{\frac{1}{2q}}\Big(\frac{\sqrt{\lvert a\rvert}}{q}x^q\Big) + C_2\sqrt{x}\, Y_{\frac{1}{2q}}\Big(\frac{\sqrt{\lvert a\rvert}}{q}x^q\Big)$ if $a < 0$ $y = C_1\sqrt{x}\, I_{\frac{1}{2q}}\Big(\frac{\sqrt{a}}{q}x^q\Big) + C_2\sqrt{x}\, K_{\frac{1}{2q}}\Big(\frac{\sqrt{a}}{q}x^q\Big)$ if $a > 0$	$q = \frac{1}{2}(k+2)$
$y''_{xx} + ay'_x + (bx + c)y = 0$	$y = e^{-ax/2}\sqrt{\xi}\,\big[C_1 J_{1/3}\big(\frac{2}{3}\sqrt{b}\,\xi^{3/2}\big) + C_2 Y_{1/3}\big(\frac{2}{3}\sqrt{b}\,\xi^{3/2}\big)\big]$	$\xi = x + \dfrac{4c - a^2}{4b}$
$xy''_{xx} + ay'_x + by = 0$	$y = x^{\frac{1-a}{2}}\big[C_1 J_\nu\big(2\sqrt{bx}\,\big) + C_2 Y_\nu\big(2\sqrt{bx}\,\big)\big]$ if $bx > 0$ $y = x^{\frac{1-a}{2}}\big[C_1 I_\nu\big(2\sqrt{\lvert bx\rvert}\big) + C_2 K_\nu\big(2\sqrt{\lvert bx\rvert}\big)\big]$ if $bx < 0$	$\nu = \lvert 1 - a\rvert$
$xy''_{xx} + ay'_x + bxy = 0$	$y = x^{\frac{1-a}{2}}\big[C_1 J_\nu\big(\sqrt{b}\,x\big) + C_2 Y_\nu\big(\sqrt{b}\,x\big)\big]$ if $b > 0$ $y = x^{\frac{1-a}{2}}\big[C_1 I_\nu\big(\sqrt{\lvert b\rvert}\,x\big) + C_2 K_\nu\big(\sqrt{\lvert b\rvert}\,x\big)\big]$ if $b < 0$	$\nu = \frac{1}{2}\lvert 1 - a\rvert$
$xy''_{xx} + ay'_x + bx^k y = 0$	$y = x^{\frac{1-a}{2}}\Big[C_1 J_\nu\Big(\frac{2\sqrt{b}}{k+1}x^{\frac{k+1}{2}}\Big) + C_2 Y_\nu\Big(\frac{2\sqrt{b}}{k+1}x^{\frac{k+1}{2}}\Big)\Big]$	$\nu = \dfrac{\lvert 1 - a\rvert}{k+1}$
$x^2 y''_{xx} + xy'_x + (x^2 - \nu^2)y = 0$	$y = C_1 J_\nu(x) + C_2 Y_\nu(x)$	The Bessel equation
$x^2 y''_{xx} + xy'_x - (x^2 + \nu^2)y = 0$	$y = C_1 I_\nu(x) + C_2 K_\nu(x)$	The modified Bessel equation
$y''_{xx} + ae^{\lambda x}y = 0$	$y = C_1 J_0(z) + C_2 Y_0(z)$	$z = \dfrac{2\sqrt{a}}{\lambda}e^{\lambda x/2}$
$y''_{xx} + (ae^x - b)y = 0$	$y = C_1 J_{2\sqrt{b}}\big(2\sqrt{a}\,e^{x/2}\big) + C_2 Y_{2\sqrt{b}}\big(2\sqrt{a}\,e^{x/2}\big)$	
$y''_{xx} + ay'_x + (be^{\lambda x} + c)y = 0$	$y = e^{-ax/2}\big[C_1 J_\nu\big(2\lambda^{-1}\sqrt{b}\,e^{\lambda x/2}\big) + C_2 Y_\nu\big(2\lambda^{-1}\sqrt{b}\,e^{\lambda x/2}\big)\big]$	$\nu = \dfrac{1}{\lambda}\sqrt{a^2 - 4c}$

2°. The *modified Bessel equation* has the form

$$x^2 y''_{xx} + xy'_x - (x^2 + \nu^2)y = 0.$$

It can be reduced to the Bessel equation by means of the substitution $x = i\bar{x}$ ($i^2 = -1$).

The general solution of the modified Bessel equation is given by

$$y = C_1 I_\nu(x) + C_2 K_\nu(x),$$

where $I_\nu(x)$ and $K_\nu(x)$ are *modified Bessel functions* of the first and second kind:

$$I_\nu(x) = \sum_{k=0}^{\infty} \frac{(x/2)^{2k+\nu}}{k!\,\Gamma(\nu + k + 1)}, \qquad K_\nu(x) = \frac{\pi}{2}\,\frac{I_{-\nu}(x) - I_\nu(x)}{\sin \pi\nu}.$$

The modified Bessel functions are described in Subsection M13.7 in detail.

3°. Table M11.2. lists some second-order linear equations whose solutions are expressed in terms of Bessel functions and modified Bessel functions.

► **Nonhomogeneous linear equations. The existence theorem.** A second-order nonhomogeneous linear equation has the form

$$f_2(x)y''_{xx} + f_1(x)y'_x + f_0(x)y = g(x). \qquad \text{(M11.2.1.6)}$$

THEOREM (EXISTENCE AND UNIQUENESS). *On an open interval $a<x<b$, let the functions f_2, f_1, f_0, and g be continuous and $f_2 \neq 0$. Also let*

$$y(x_0) = A, \quad y'_x(x_0) = B$$

be arbitrary initial conditions, where x_0 is any point such that $a < x_0 < b$, and A and B are arbitrary prescribed numbers. Then a solution of equation (M11.2.1.6) exists and is unique. This solution is defined for all $x \in (a, b)$.

► **Formulas for the general solution.**

1°. The general solution of the nonhomogeneous linear equation (M11.2.1.6) is the sum of the general solution of the corresponding homogeneous linear equation (M11.2.1.1) and any particular solution of the nonhomogeneous equation (M11.2.1.6).

2°. Let $y_1 = y_1(x)$, $y_2 = y_2(x)$ be a fundamental system of solutions of the corresponding homogeneous equation, with $g \equiv 0$. Then the general solution of nonhomogeneous equation (M11.2.1.6) can be represented as

$$y = C_1y_1 + C_2y_2 + y_2 \int y_1 \frac{g}{f_2}\frac{dx}{W} - y_1 \int y_2 \frac{g}{f_2}\frac{dx}{W}, \qquad \text{(M11.2.1.7)}$$

where $W = y_1(y_2)'_x - y_2(y_1)'_x$ is the Wronskian determinant.

Remark. Given a nontrivial particular solution $y_1 = y_1(x)$ of the homogeneous equation (with $g \equiv 0$), a second particular solution $y_2 = y_2(x)$ of the homogeneous equation can be calculated from formula (M11.2.1.3). Then the general solution of equation (M11.2.1.6) can be constructed by (M11.2.1.3) and (M11.2.1.7).

3°. Let $\bar{y}_1$ and $\bar{y}_2$ be respective solutions of the nonhomogeneous differential equations $\mathrm{L}[\bar{y}_1] = g_1(x)$ and $\mathrm{L}[\bar{y}_2] = g_2(x)$, which have the same left-hand side but different right-hand sides, where $\mathrm{L}[y]$ is the left-hand side of equation (M11.2.1.6). Then the function $\bar{y} = \bar{y}_1 + \bar{y}_2$ is also a solution of the equation $\mathrm{L}[\bar{y}] = g_1(x) + g_2(x)$.

M11.2.2. Representation of Solutions as a Series in the Independent Variable

► **Equation coefficients are representable in power series form.** Let us consider a homogeneous linear differential equation of the general form

$$y''_{xx} + f(x)y'_x + g(x)y = 0. \qquad \text{(M11.2.2.1)}$$

Assume that the functions $f(x)$ and $g(x)$ are representable, in a neighborhood of a point $x = x_0$, in power series form,

$$f(x) = \sum_{n=0}^{\infty} A_n(x-x_0)^n, \qquad g(x) = \sum_{n=0}^{\infty} B_n(x-x_0)^n, \qquad \text{(M11.2.2.2)}$$

on the interval $|x-x_0|<R$, where R stands for the minimum radius of convergence of the two series in (M11.2.2.2). In this case, the point $x=x_0$ is referred to as an *ordinary point*, and equation (M11.2.2.1) possesses two linearly independent solutions of the form

$$y_1(x)=\sum_{n=0}^{\infty}a_n(x-x_0)^n,\qquad y_2(x)=\sum_{n=0}^{\infty}b_n(x-x_0)^n. \tag{M11.2.2.3}$$

The coefficients a_n and b_n are determined by substituting the series (M11.2.2.2) and (M11.2.2.3) into equation (M11.2.2.1) followed by matching the coefficients of like powers of $(x-x_0)$.*

► **Equation coefficients have poles at some point.** Assume that the functions $f(x)$ and $g(x)$ are representable, in a neighborhood of a point $x=x_0$, in the form

$$f(x)=\sum_{n=-1}^{\infty}A_n(x-x_0)^n,\qquad g(x)=\sum_{n=-2}^{\infty}B_n(x-x_0)^n, \tag{M11.2.2.4}$$

on the interval $|x-x_0|<R$. In this case, the point $x=x_0$ is referred to as a *regular singular point*. Let λ_1 and λ_2 be roots of the quadratic equation

$$\lambda^2+(A_{-1}-1)\lambda+B_{-2}=0.$$

Depending on the values of λ_1 and λ_2, three cases are possible. These cases are considered below.

1. If $\lambda_1\neq\lambda_2$ and $\lambda_1-\lambda_2$ is not an integer, equation (M11.2.2.1) has two linearly independent solutions of the form

$$\begin{aligned}y_1(x)&=|x-x_0|^{\lambda_1}\Bigl[1+\sum_{n=1}^{\infty}a_n(x-x_0)^n\Bigr],\\ y_2(x)&=|x-x_0|^{\lambda_2}\Bigl[1+\sum_{n=1}^{\infty}b_n(x-x_0)^n\Bigr].\end{aligned} \tag{M11.2.2.5}$$

2. If $\lambda_1=\lambda_2=\lambda$, equation (M11.2.2.1) possesses two linearly independent solutions:

$$\begin{aligned}y_1(x)&=|x-x_0|^{\lambda}\Bigl[1+\sum_{n=1}^{\infty}a_n(x-x_0)^n\Bigr],\\ y_2(x)&=y_1(x)\ln|x-x_0|+|x-x_0|^{\lambda}\sum_{n=0}^{\infty}b_n(x-x_0)^n.\end{aligned}$$

3. If $\lambda_1=\lambda_2+N$, where N is a positive integer, equation (M11.2.2.1) has two linearly independent solutions of the form

$$\begin{aligned}y_1(x)&=|x-x_0|^{\lambda_1}\Bigl[1+\sum_{n=1}^{\infty}a_n(x-x_0)^n\Bigr],\\ y_2(x)&=ky_1(x)\ln|x-x_0|+|x-x_0|^{\lambda_2}\sum_{n=0}^{\infty}b_n(x-x_0)^n,\end{aligned}$$

where k is a constant to be determined (it may be equal to zero).

---

* Prior to that, the terms containing the same powers $(x-x_0)^k$, $k=0,1,\ldots$, should be collected.

To construct the solution in each of the three cases, the following procedure should be performed: substitute the above expressions of y_1 (resp., y_2) into the original equation (M11.2.2.1), taking into account (M11.2.2.4), and equate the coefficients of $(x-x_0)^n$ and (resp., $(x-x_0)^n \ln|x-x_0|$) for like values of n to obtain recurrence relations for the unknown coefficients. The desired solution can be found from these recurrence relations.

M11.2.3. Boundary Value Problems

► **First, second, third, and mixed boundary value problems ($x_1 \le x \le x_2$).** We consider the second-order nonhomogeneous linear differential equation

$$y''_{xx} + f(x)y'_x + g(x)y = h(x). \qquad \text{(M11.2.3.1)}$$

1°. *The first boundary value problem*: Find a solution of equation (M11.2.3.1) satisfying the boundary conditions

$$y = a_1 \quad \text{at} \quad x = x_1, \qquad y = a_2 \quad \text{at} \quad x = x_2. \qquad \text{(M11.2.3.2)}$$

(The values of the unknown are prescribed at two distinct points x_1 and x_2.)

2°. *The second boundary value problem*: Find a solution of equation (M11.2.3.1) satisfying the boundary conditions

$$y'_x = a_1 \quad \text{at} \quad x = x_1, \qquad y'_x = a_2 \quad \text{at} \quad x = x_2. \qquad \text{(M11.2.3.3)}$$

(The values of the derivative of the unknown are prescribed at two distinct points x_1 and x_2.)

3°. *The third boundary value problem*: Find a solution of equation (M11.2.3.1) satisfying the boundary conditions

$$\begin{aligned} y'_x + k_1 y &= a_1 \quad \text{at} \quad x = x_1,\\ y'_x + k_2 y &= a_2 \quad \text{at} \quad x = x_2. \end{aligned} \qquad \text{(M11.2.3.4)}$$

4°. *The mixed boundary value problem*: Find a solution of equation (M11.2.3.1) satisfying the boundary conditions

$$y = a_1 \quad \text{at} \quad x = x_1, \qquad y'_x = a_2 \quad \text{at} \quad x = x_2. \qquad \text{(M11.2.3.5)}$$

(The unknown is prescribed at one point, and its derivative at another point.)

Conditions (M11.2.3.2), (M11.2.3.3), (M11.2.3.4), and (M11.2.3.5) are called *homogeneous* if $a_1 = a_2 = 0$.

► **Simplification of boundary conditions. The self-adjoint form of equations.**

1°. Nonhomogeneous boundary conditions can be reduced to homogeneous ones by the change of variable $z = A_2x^2 + A_1x + A_0 + y$ (the constants A_2, A_1, and A_0 are selected using the method of undetermined coefficients). In particular, the nonhomogeneous boundary conditions of the first kind (M11.2.3.2) can be reduced to homogeneous boundary conditions by the linear change of variable

$$z = y - \frac{a_2 - a_1}{x_2 - x_1}(x - x_1) - a_1.$$

2°. On multiplying by $p(x) = \exp\Bigl[\int f(x)\,dx\Bigr]$, one reduces equation (M11.2.3.1) to the self-adjoint form:

$$[p(x)y'_x]'_x + q(x)y = r(x). \qquad \text{(M11.2.3.6)}$$

Without loss of generality, we can further consider equation (M11.2.3.6) instead of (M11.2.3.1). We assume that the functions p, p'_x, q, and r are continuous on the interval $x_1 \le x \le x_2$, and p is positive.

► **Green's function. Linear problems for nonhomogeneous equations.** The *Green's function* of the first boundary value problem for equation (M11.2.3.6) with homogeneous boundary conditions (M11.2.3.2) is a function of two variables $G(x,\xi)$ that satisfies the following conditions:

1°. $G(x,\xi)$ is continuous in x for fixed ξ, with $x_1 \le x \le x_2$ and $x_1 \le \xi \le x_2$.

2°. $G(x,\xi)$ is a solution of the homogeneous equation (M11.2.3.6), with $r = 0$, for all $x_1 < x < x_2$ exclusive of the point $x = \xi$.

3°. $G(x,\xi)$ satisfies the homogeneous boundary conditions $G(x_1,\xi) = G(x_2,\xi) = 0$.

4°. The derivative $G'_x(x,\xi)$ has a jump of $1/p(\xi)$ at the point $x = \xi$, that is,

$$G'_x(x,\xi)\big|_{x\to\xi,\,x>\xi} - G'_x(x,\xi)\big|_{x\to\xi,\,x<\xi} = \frac{1}{p(\xi)}.$$

For the second, third, and mixed boundary value problems, the Green's function is defined likewise except that in 3° one adopts, respectively, the homogeneous boundary conditions (M11.2.3.3), (M11.2.3.4), and (M11.2.3.5), with $a_1 = a_2 = 0$.

The solution of the nonhomogeneous equation (M11.2.3.6) subject to appropriate homogeneous boundary conditions is expressed in terms of the Green's function as follows:*

$$y(x) = \int_{x_1}^{x_2} G(x,\xi)r(\xi)\,d\xi.$$

► **Representation of the Green's function in terms of particular solutions.** We consider the first boundary value problem. Let $y_1(x)$ and $y_2(x)$ be linearly independent particular solutions of the homogeneous equation (M11.2.3.6), with $r = 0$, that satisfy the conditions

$$y_1(x_1) = 0, \qquad y_2(x_2) = 0.$$

(Each of the solutions satisfies one of the homogeneous boundary conditions.)

The Green's function is expressed in terms of solutions of the homogeneous equation as follows:

$$G(x,\xi) = \begin{cases} \dfrac{y_1(x)y_2(\xi)}{p(\xi)W(\xi)} & \text{for } x_1 \le x \le \xi, \\[2ex] \dfrac{y_1(\xi)y_2(x)}{p(\xi)W(\xi)} & \text{for } \xi \le x \le x_2, \end{cases} \tag{M11.2.3.7}$$

where $W(x) = y_1(x)y'_2(x) - y'_1(x)y_2(x)$ is the Wronskian determinant.

Remark. Formula (M11.2.3.7) can also be used to construct the Green's functions for the second, third, and mixed boundary value problems. To this end, one should find two linearly independent solutions, $y_1(x)$ and $y_2(x)$, of the homogeneous equation; the former satisfies the corresponding homogeneous boundary condition at $x = x_1$ and the latter satisfies the one at $x = x_2$.

M11.2.4. Eigenvalue Problems

► **Sturm–Liouville problem.** Consider the second-order homogeneous linear differential equation

$$[p(x)y'_x]'_x + [\lambda\rho(x) - q(x)]y = 0 \tag{M11.2.4.1}$$

---

* The homogeneous boundary value problem, with $r(x) = 0$ and $a_1 = a_2 = 0$, is assumed to have only the trivial solution.

subject to linear boundary conditions of the general form

$$\begin{aligned} s_1 y'_x + k_1 y = 0 \quad &\text{at} \quad x = x_1, \\ s_2 y'_x + k_2 y = 0 \quad &\text{at} \quad x = x_2. \end{aligned} \tag{M11.2.4.2}$$

It is assumed that the functions p, p'_x, ρ, and q are continuous, and p and ρ are positive on an interval $x_1 \le x \le x_2$. It is also assumed that $|s_1| + |k_1| > 0$ and $|s_2| + |k_2| > 0$.

The *Sturm–Liouville problem*: Find the values λ_n of the parameter λ at which problem (M11.2.4.1)–(M11.2.4.2) has a nontrivial solution. Such λ_n are called *eigenvalues* and the corresponding solutions $y_n = y_n(x)$ are called *eigenfunctions* of the Sturm–Liouville problem (M11.2.4.1)–(M11.2.4.2).

► General properties of the Sturm–Liouville problem (M11.2.4.1)–(M11.2.4.2).

1°. There are infinitely (countably) many eigenvalues. All eigenvalues can be ordered so that $\lambda_1 < \lambda_2 < \lambda_3 < \cdots$. Moreover, $\lambda_n \to \infty$ as $n \to \infty$; hence, there can only be a finite number of negative eigenvalues.

2°. The eigenfunctions are defined up to a constant factor. Each eigenfunction $y_n(x)$ has precisely $n - 1$ zeros on the open interval (x_1, x_2).

3°. Any two eigenfunctions $y_n(x)$ and $y_m(x)$, $n \neq m$, are orthogonal with weight $\rho(x)$ on the interval $x_1 \le x \le x_2$:

$$\int_{x_1}^{x_2} \rho(x) y_n(x) y_m(x)\, dx = 0 \quad \text{if} \quad n \neq m.$$

4°. An arbitrary function $F(x)$ that has a continuous derivative and satisfies the boundary conditions of the Sturm–Liouville problem can be decomposed into an absolutely and uniformly convergent series in the eigenfunctions

$$F(x) = \sum_{n=1}^{\infty} F_n y_n(x),$$

where the Fourier coefficients F_n of $F(x)$ are calculated by

$$F_n = \frac{1}{\|y_n\|^2} \int_{x_1}^{x_2} \rho(x) F(x) y_n(x)\, dx, \qquad \|y_n\|^2 = \int_{x_1}^{x_2} \rho(x) y_n^2(x)\, dx.$$

5°. If the conditions

$$q(x) \ge 0, \quad s_1 k_1 \le 0, \quad s_2 k_2 \ge 0 \tag{M11.2.4.3}$$

hold true, there are no negative eigenvalues. If $q \equiv 0$ and $k_1 = k_2 = 0$, the least eigenvalue is $\lambda_1 = 0$, to which there corresponds an eigenfunction $y_1 = \text{const}$. In the other cases where conditions (M11.2.4.3) are satisfied, all eigenvalues are positive.

6°. The following asymptotic formula is valid for eigenvalues as $n \to \infty$:

$$\lambda_n = \frac{\pi^2 n^2}{\Delta^2} + O(1), \qquad \Delta = \int_{x_1}^{x_2} \sqrt{\frac{\rho(x)}{p(x)}}\, dx. \tag{M11.2.4.4}$$

Remark 1. Equation (M11.2.4.1) can be reduced to the case where $p(x) \equiv 1$ and $\rho(x) \equiv 1$ by the change of variables

$$\zeta = \int \sqrt{\frac{\rho(x)}{p(x)}}\, dx, \qquad u(\zeta) = \bigl[p(x)\rho(x)\bigr]^{1/4} y(x).$$

In this case, the boundary conditions are transformed to boundary conditions of a similar form.

TABLE M11.3
Example estimates of the first eigenvalue λ_1 in Sturm–Liouville problems with boundary conditions of the first kind $y(0) = y(1) = 0$ obtained using the Rayleigh–Ritz principle [the right-hand side of relation (M11.2.4.6)].

Equation	Test function	λ_1, approximate	λ_1, exact
$y''_{xx} + \lambda(1 + x^2)^{-2}y = 0$	$z = \sin \pi x$	15.337	15.0
$y''_{xx} + \lambda(4 - x^2)^{-2}y = 0$	$z = \sin \pi x$	135.317	134.837
$y''_{xx} + \lambda(1 + \sin \pi x)y = 0$	$z = \sin \pi x$ $z = x(1 - x)$	$0.54105\,\pi^2$ $0.55204\,\pi^2$	$0.54032\,\pi^2$ $0.54032\,\pi^2$
$(\sqrt{1 + x}\, y'_x)'_x + \lambda y = 0$	$z = \sin \pi x$	11.9956	11.8985

Remark 2. The second-order linear equation

$$\varphi_2(x)y''_{xx} + \varphi_1(x)y'_x + [\lambda + \varphi_0(x)]y = 0$$

can be represented in the form of equation (M11.2.4.1) where $p(x)$, $\rho(x)$, and $q(x)$ are given by

$$p(x) = \exp\left[\int \frac{\varphi_1(x)}{\varphi_2(x)}\,dx\right],\quad \rho(x) = \frac{1}{\varphi_2(x)}\exp\left[\int \frac{\varphi_1(x)}{\varphi_2(x)}\,dx\right],\quad q(x) = -\frac{\varphi_0(x)}{\varphi_2(x)}\exp\left[\int \frac{\varphi_1(x)}{\varphi_2(x)}\,dx\right].$$

► **Problems with boundary conditions of the first kind.** Let us note some special properties of the Sturm–Liouville problem that is the first boundary value problem for equation (M11.2.4.1) with the boundary conditions

$$y = 0 \quad \text{at} \quad x = x_1, \qquad y = 0 \quad \text{at} \quad x = x_2. \tag{M11.2.4.5}$$

1°. For $n \to \infty$, the asymptotic relation (M11.2.4.4) can be used to estimate the eigenvalues λ_n. In this case, the asymptotic formula

$$\frac{y_n(x)}{\|y_n\|} = \left[\frac{4}{\Delta^2 p(x)\rho(x)}\right]^{1/4} \sin\left[\frac{\pi n}{\Delta}\int_{x_1}^{x}\sqrt{\frac{\rho(x)}{p(x)}}\,dx\right] + O\Big(\frac{1}{n}\Big), \qquad \Delta = \int_{x_1}^{x_2}\sqrt{\frac{\rho(x)}{p(x)}}\,dx$$

holds true for the eigenfunctions $y_n(x)$.

2°. If $q \ge 0$, the following upper estimate holds for the least eigenvalue (*Rayleigh–Ritz principle*):

$$\lambda_1 \le \frac{\displaystyle\int_{x_1}^{x_2}\big[p(x)(z'_x)^2 + q(x)z^2\big]\,dx}{\displaystyle\int_{x_1}^{x_2}\rho(x)z^2\,dx}, \tag{M11.2.4.6}$$

where $z = z(x)$ is any twice differentiable function that satisfies the conditions $z(x_1) = z(x_2) = 0$. The equality in (M11.2.4.6) is attained if $z = y_1(x)$, where $y_1(x)$ is the eigenfunction corresponding to the eigenvalue λ_1. One can take $z = (x - x_1)(x_2 - x)$ or $z = \sin\left[\dfrac{\pi(x - x_1)}{x_2 - x_1}\right]$ in (M11.2.4.6) to obtain specific estimates.

It is significant to note that the left-hand side of (M11.2.4.6) usually gives a fairly precise estimate of the first eigenvalue (see Table M11.3).

3°. The extension of the interval $[x_1, x_2]$ results in decreasing the eigenvalues.

4°. Let the inequalities

$$0 < p_{\min} \le p(x) \le p_{\max}, \quad 0 < \rho_{\min} \le \rho(x) \le \rho_{\max}, \quad 0 < q_{\min} \le q(x) \le q_{\max}$$

be satisfied. Then the following bilateral estimates hold:

$$\frac{p_{\min}}{\rho_{\max}} \frac{\pi^2 n^2}{(x_2 - x_1)^2} + \frac{q_{\min}}{\rho_{\max}} \le \lambda_n \le \frac{p_{\max}}{\rho_{\min}} \frac{\pi^2 n^2}{(x_2 - x_1)^2} + \frac{q_{\max}}{\rho_{\min}}.$$

5°. In engineering calculations for eigenvalues, the approximate formula

$$\lambda_n = \frac{\pi^2 n^2}{\Delta^2} + \frac{1}{x_2 - x_1} \int_{x_1}^{x_2} \frac{q(x)}{\rho(x)}\,dx, \qquad \Delta = \int_{x_1}^{x_2} \sqrt{\frac{\rho(x)}{p(x)}}\,dx \tag{M11.2.4.7}$$

may be quite useful. This formula provides an exact result if $p(x)\rho(x) = \text{const}$ and $q(x)/\rho(x) = \text{const}$ (in particular, for constant equation coefficients, $p = p_0$, $q = q_0$, and $\rho = \rho_0$) and gives a correct asymptotic behavior of (M11.2.4.4) for any $p(x)$, $q(x)$, and $\rho(x)$. In addition, relation (M11.2.4.7) gives two correct leading asymptotic terms as $n \to \infty$ if $p(x) = \text{const}$ and $\rho(x) = \text{const}$ [and also if $p(x)\rho(x) = \text{const}$].

6°. Suppose that $p(x) = \rho(x) = 1$ and the function $q(x)$ has a continuous derivative. The following asymptotic relations hold for eigenvalues λ_n and eigenfunctions $y_n(x)$ as $n \to \infty$:

$$\begin{aligned} \sqrt{\lambda_n} &= \frac{\pi n}{x_2 - x_1} + \frac{1}{\pi n} Q(x_1, x_2) + O\Big(\frac{1}{n^2}\Big), \\ y_n(x) &= \sin \frac{\pi n (x - x_1)}{x_2 - x_1} - \frac{1}{\pi n} \Big[(x_1 - x) Q(x, x_2) + (x_2 - x) Q(x_1, x)\Big] \cos \frac{\pi n (x - x_1)}{x_2 - x_1} + O\Big(\frac{1}{n^2}\Big), \end{aligned}$$

where

$$Q(u, v) = \frac{1}{2} \int_u^v q(x)\,dx. \tag{M11.2.4.8}$$

7°. Let us consider the eigenvalue problem for the equation with a small parameter

$$y''_{xx} + [\lambda + \varepsilon q(x)] y = 0 \qquad (\varepsilon \to 0)$$

subject to the boundary conditions (M11.2.4.5) with $x_1 = 0$ and $x_2 = 1$. We assume that $q(x) = q(-x)$.

This problem has the following eigenvalues and eigenfunctions:

$$\begin{aligned} \lambda_n &= \pi^2 n^2 - \varepsilon A_{nn} + \frac{\varepsilon^2}{\pi^2} \sum_{k \ne n} \frac{A_{nk}^2}{n^2 - k^2} + O(\varepsilon^3), \qquad A_{nk} = 2 \int_0^1 q(x) \sin(\pi n x) \sin(\pi k x)\,dx; \\ y_n(x) &= \sqrt{2}\, \sin(\pi n x) - \varepsilon \frac{\sqrt{2}}{\pi^2} \sum_{k \ne n} \frac{A_{nk}}{n^2 - k^2} \sin(\pi k x) + O(\varepsilon^2). \end{aligned}$$

Here, the summation is carried out over k from 1 to ∞. The next term in the expansion of y_n can be found in Nayfeh (1973).

M11.3. Second-Order Nonlinear Differential Equations

M11.3.1. Form of the General Solution. Cauchy Problem

► **Equations solved for the derivative. General solution.** A *second-order ordinary differential equation* solved for the highest derivative has the form

$$y''_{xx} = f(x, y, y'_x). \qquad \text{(M11.3.1.1)}$$

The general solution of this equation depends on two arbitrary constants, C_1 and C_2. In some cases, the general solution can be written in explicit form, $y = \varphi(x, C_1, C_2)$, but more often implicit or parametric forms of the general solution are encountered.

► **Cauchy problem. The existence and uniqueness theorem.** *Cauchy problem*: Find a solution of equation (M11.3.1.1) satisfying the *initial conditions*

$$y(x_0) = y_0, \qquad y'_x(x_0) = y_1. \qquad \text{(M11.3.1.2)}$$

(At a point $x = x_0$, the value of the unknown function, y_0, and its derivative, y_1, are prescribed.)

EXISTENCE AND UNIQUENESS THEOREM. *Let $f(x, y, z)$ be a continuous function in all its arguments in a neighborhood of a point (x_0, y_0, y_1) and let f have bounded partial derivatives f_y and f_z in this neighborhood, or the Lipschitz condition is satisfied: $|f(x, y, z) - f(x, \bar{y}, \bar{z})| \le A\bigl(|y-\bar{y}| + |z-\bar{z}|\bigr)$, where A is some positive number. Then a solution of equation (M11.3.1.1) satisfying the initial conditions (M11.3.1.2) exists and is unique.*

M11.3.2. Equations Admitting Reduction of Order

► **Equations not containing y explicitly.** In the general case, a second-order equation that does not contain y explicitly has the form

$$F(x, y'_x, y''_{xx}) = 0. \qquad \text{(M11.3.2.1)}$$

Such equations remain unchanged under an arbitrary translation of the dependent variable: $y \to y + \text{const}$. The substitution $y'_x = z(x)$, $y''_{xx} = z'_x(x)$ brings (M11.3.2.1) to a first-order equation: $F(x, z, z'_x) = 0$.

► **Equations not containing x explicitly (autonomous equations).** In the general case, a second-order equation that does not contain x explicitly has the form

$$F(y, y'_x, y''_{xx}) = 0. \qquad \text{(M11.3.2.2)}$$

Such equations remain unchanged under an arbitrary translation of the independent variable: $x \to x + \text{const}$. Using the substitution $y'_x = w(y)$, where y plays the role of the independent variable, and taking into account the relations $y''_{xx} = w'_x = w'_y y'_x = w'_y w$, one can reduce (M11.3.2.2) to a first-order equation: $F(y, w, ww'_y) = 0$.

Example 1. Consider the autonomous equation

$$y''_{xx} = f(y),$$

which often arises in the theory of heat and mass transfer and combustion. The change of variable $y'_x = w(y)$ leads to a separable first-order equation: $ww'_y = f(y)$. Integrating yields $w^2 = 2F(y) + C_1$, where $F(y) = \int f(y)\,dy$. Solving for w and returning to the original variable, we obtain the separable equation $y'_x = \pm\sqrt{2F(y) + C_1}$. Its general solution is expressed as

$$\int \frac{dy}{\sqrt{2F(y) + C_1}} = \pm x + C_2, \quad \text{where} \quad F(y) = \int f(y)\,dy.$$

Remark. The equation $y''_{xx} = f(y + ax^2 + bx + c)$ is reduced by the change of variable $u = y + ax^2 + bx + c$ to an autonomous equation, $u''_{xx} = f(u) + 2a$.

► **Equations of the form $F(ax+by, y'_x, y''_{xx}) = 0$.** Such equations are invariant under simultaneous translations of the independent and dependent variables in accordance with the rule $x \to x + bc$, $y \to y - ac$, where c is an arbitrary constant.

For $b = 0$, see equation (M11.3.2.1). For $b \neq 0$, the substitution $bw = ax + by$ leads to the autonomous equation, $F(bw, w'_x - a/b, w''_{xx}) = 0$, that does not contain x explicitly.

► **Homogeneous equations.**

1°. The *equations homogeneous in the independent variable* remain unchanged under scaling of the independent variable, $x \to \alpha x$, where α is an arbitrary nonzero number. In the general case, such equations can be written in the form

$$F(y, xy'_x, x^2 y''_{xx}) = 0. \tag{M11.3.2.3}$$

The substitution $z(y) = xy'_x$ leads to a first-order equation, $F(y, z, zz'_y - z) = 0$.

2°. The *equations homogeneous in the dependent variable* remain unchanged under scaling of the variable sought, $y \to \alpha y$, where α is an arbitrary nonzero number. In the general case, such equations can be written in the form

$$F(x, y'_x/y, y''_{xx}/y) = 0. \tag{M11.3.2.4}$$

The substitution $z(x) = y'_x/y$ leads to a first-order equation, $F(x, z, z'_x + z^2) = 0$.

3°. The *equations homogeneous in both variables* are invariant under simultaneous scaling (dilatation) of the independent and dependent variables, $x \to \alpha x$ and $y \to \alpha y$, where α is an arbitrary nonzero number. In the general case, such equations can be written in the form

$$F(y/x, y'_x, xy''_{xx}) = 0. \tag{M11.3.2.5}$$

The transformation $t = \ln|x|$, $w = y/x$ leads to the autonomous equation, $F(w, w'_t + w, w''_{tt} + w'_t) = 0$, that does not contain t explicitly.

Example 2. The homogeneous equation

$$xy''_{xx} - y'_x = f(y/x)$$

is reduced by the transformation $t = \ln|x|$, $w = y/x$ to the autonomous form: $w''_{tt} = f(w) + w$. For solution of this equation, see Example 1 above (the notation of the right-hand side has to be changed there).

► **Generalized homogeneous equations.**

1°. The *generalized homogeneous equations* remain unchanged under simultaneous scaling of the independent and dependent variables in accordance with the rule $x \to \alpha x$ and $y \to \alpha^k y$, where α is an arbitrary nonzero number and k is some number. Such equations can be written in the form

$$F(x^{-k} y, x^{1-k} y'_x, x^{2-k} y''_{xx}) = 0. \tag{M11.3.2.6}$$

The transformation $t = \ln x$, $w = x^{-k} y$ leads to the autonomous equation,

$$F\big(w, w'_t + kw, w''_{tt} + (2k-1)w'_t + k(k-1)w\big) = 0,$$

that does not contain t explicitly.

2°. The most general form of representation of generalized homogeneous equations is as follows:

$$\mathcal{F}(x^n y^m, xy'_x/y, x^2 y''_{xx}/y) = 0. \qquad \text{(M11.3.2.7)}$$

The transformation $z = x^n y^m$, $u = xy'_x/y$ reduces this equation to the first-order equation

$$\mathcal{F}\big(z, u, z(mu+n)u'_z - u + u^2\big) = 0.$$

Remark. For $m \neq 0$, equation (M11.3.2.7) is equivalent to equation (M11.3.2.6) in which $k = -n/m$. To the particular values $n = 0$ and $m = 0$ there correspond equations (M11.3.2.3) and (M11.3.2.4) homogeneous in the independent and dependent variables, respectively. For $n = -m \neq 0$, we have an equation homogeneous in both variables, which is equivalent to equation (M11.3.2.5).

► **Equations invariant under scaling–translation transformations.**

1°. The equations of the form

$$F(e^{\lambda x} y, e^{\lambda x} y'_x, e^{\lambda x} y''_{xx}) = 0 \qquad \text{(M11.3.2.8)}$$

remain unchanged under simultaneous translation and scaling of variables, $x \to x + \alpha$ and $y \to \beta y$, where $\beta = e^{-\alpha\lambda}$ and α is an arbitrary number. The substitution $w = e^{\lambda x} y$ brings (M11.3.2.8) to the autonomous equation, $F(w,\ w'_x - \lambda w,\ w''_{xx} - 2\lambda w'_x + \lambda^2 w) = 0$, that does not contain x explicitly.

2°. The equation

$$F(e^{\lambda x} y^n, y'_x/y, y''_{xx}/y) = 0 \qquad \text{(M11.3.2.9)}$$

is invariant under the simultaneous translation and scaling of variables, $x \to x + \alpha$ and $y \to \beta y$, where $\beta = e^{-\alpha\lambda/n}$ and α is an arbitrary number. The transformation $z = e^{\lambda x} y^n$, $w = y'_x/y$ brings (M11.3.2.9) to a first-order equation: $F\big(z, w, z(nw + \lambda)w'_z + w^2\big) = 0$.

3°. The equation

$$F(x^n e^{\lambda y}, xy'_x, x^2 y''_{xx}) = 0 \qquad \text{(M11.3.2.10)}$$

is invariant under the simultaneous scaling and translation of variables, $x \to \alpha x$ and $y \to y + \beta$, where $\alpha = e^{-\beta\lambda/n}$ and β is an arbitrary number. The transformation $z = x^n e^{\lambda y}$, $w = xy'_x$ brings (M11.3.2.10) to a first-order equation: $F\big(z, w, z(\lambda w + n)w'_z - w\big) = 0$.

► **Equations of the form $\boldsymbol{F(x, xy'_x - y, y''_{xx}) = 0}$.** The substitution $w(x) = xy'_x - y$ leads to a first-order equation: $F(x, w, w'_x/x) = 0$.

M11.3.3. Methods of Regular Series Expansions with Respect to the Independent Variable

A solution of the Cauchy problem

$$y''_{xx} = f(x, y, y'_x), \qquad \text{(M11.3.3.1)}$$

$$y(x_0) = y_0, \quad y'_x(x_0) = y_1 \qquad \text{(M11.3.3.2)}$$

can be sought in the form of a Taylor series in powers of the difference $(x - x_0)$, specifically:

$$y(x) = y(x_0) + y'_x(x_0)(x - x_0) + \frac{y''_{xx}(x_0)}{2!}(x - x_0)^2 + \frac{y'''_{xxx}(x_0)}{3!}(x - x_0)^3 + \cdots. \qquad \text{(M11.3.3.3)}$$

The first two coefficients $y(x_0)$ and $y'_x(x_0)$ in solution (M11.3.3.3) are defined by the initial conditions (M11.3.3.2). The values of the subsequent derivatives of y at the point $x = x_0$ are determined from equation (M11.3.3.1) and its derivative equations (obtained by successive differentiation of the equation) taking into account the initial conditions (M11.3.3.2). In particular, setting $x = x_0$ in (M11.3.3.1) and substituting (M11.3.3.2), we obtain the value of the second derivative:

$$y''_{xx}(x_0) = f(x_0, y_0, y_1). \qquad \text{(M11.3.3.4)}$$

Further, differentiating (M11.3.3.1) yields

$$y'''_{xxx} = f_x(x, y, y'_x) + f_y(x, y, y'_x)y'_x + f_{y'_x}(x, y, y'_x)y''_{xx}. \qquad \text{(M11.3.3.5)}$$

On substituting $x = x_0$, the initial conditions (M11.3.3.2), and the expression of $y''_{xx}(x_0)$ of (M11.3.3.4) into the right-hand side of equation (M11.3.3.5), we calculate the value of the third derivative:

$$y'''_{xxx}(x_0) = f_x(x_0, y_0, y_1) + y_1 f_y(x_0, y_0, y_1) + f(x_0, y_0, y_1) f_{y'_x}(x_0, y_0, y_1).$$

The subsequent derivatives of the unknown are determined likewise.

The thus obtained solution (M11.3.3.3) can only be used in a small neighborhood of the point $x = x_0$.

Example. Consider the following Cauchy problem for a second-order nonlinear equation:

$$y''_{xx} = yy'_x + y^3; \qquad \text{(M11.3.3.6)}$$

$$y(0) = y'_x(0) = 1. \qquad \text{(M11.3.3.7)}$$

Substituting the initial values of the unknown and its derivative (M11.3.3.7) into equation (M11.3.3.6) yields the initial value of the second derivative:

$$y''_{xx}(0) = 2. \qquad \text{(M11.3.3.8)}$$

Differentiating equation (M11.3.3.6) gives

$$y'''_{xxx} = yy''_{xx} + (y'_x)^2 + 3y^2 y'_x. \qquad \text{(M11.3.3.9)}$$

Substituting here the initial values from (M11.3.3.7) and (M11.3.3.8), we obtain the initial condition for the third derivative:

$$y'''_{xxx}(0) = 6. \qquad \text{(M11.3.3.10)}$$

Differentiating (M11.3.3.9) followed by substituting (M11.3.3.7), (M11.3.3.8), and (M11.3.3.10), we find that

$$y''''_{xxxx}(0) = 24. \qquad \text{(M11.3.3.11)}$$

On substituting the initial data (M11.3.3.7), (M11.3.3.8), (M11.3.3.10), and (M11.3.3.11) into (M11.3.3.3), we arrive at the Taylor series expansion of the solution about $x = 0$:

$$y = 1 + x + x^2 + x^3 + x^4 + \cdots . \qquad \text{(M11.3.3.12)}$$

This geometric series is convergent only for $|x| < 1$. In this case, summing up the series (M11.3.3.12) gives the exact solution of the Cauchy problem (M11.3.3.6)–(M11.3.3.7) of the form $y(x) = \dfrac{1}{1-x}$.

M11.3.4. Perturbation Methods in Problems with a Small Parameter

► **Preliminary remarks.** Perturbation methods are widely used in nonlinear mechanics and theoretical physics for solving problems that are described by differential equations with a small parameter ε. The primary purpose of these methods is to obtain an approximate solution that would be equally suitable at all (small, intermediate, and large) values of the independent variable as $\varepsilon \to 0$.

It is further assumed that the order of the equation remains unchanged at $\varepsilon = 0$.

In many problems of nonlinear mechanics and theoretical physics, the independent variable is dimensionless time t. Therefore, in this subsection we use the conventional t ($0 \le t < \infty$), instead of x.

► **Method of regular (direct) expansion in powers of the small parameter.** We consider an equation of general form with a parameter ε:

$$y''_{tt} + f(t, y, y'_t, \varepsilon) = 0. \tag{M11.3.4.1}$$

We assume that the function f can be represented as a series in powers of ε:

$$f(t, y, y'_t, \varepsilon) = \sum_{n=0}^{\infty} \varepsilon^n f_n(t, y, y'_t). \tag{M11.3.4.2}$$

Solutions of the Cauchy problem and various boundary value problems for equation (M11.3.4.1) with $\varepsilon \to 0$ are sought in the form of a power series expansion:

$$y = \sum_{n=0}^{\infty} \varepsilon^n y_n(t). \tag{M11.3.4.3}$$

One should substitute expression (M11.3.4.3) into equation (M11.3.4.1) taking into account (M11.3.4.2). Then the functions f_n are expanded into a power series in the small parameter and the coefficients of like powers of ε are collected and equated to zero to obtain a system of equations for y_n:

$$y''_0 + f_0(t, y_0, y'_0) = 0, \tag{M11.3.4.4}$$

$$y''_1 + F(t, y_0, y'_0)y'_1 + G(t, y_0, y'_0)y_1 + f_1(t, y_0, y'_0) = 0, \quad F = \frac{\partial f_0}{\partial y'}, \quad G = \frac{\partial f_0}{\partial y}. \tag{M11.3.4.5}$$

Only the first two equations are written out here. The prime denotes differentiation with respect to t. To obtain the initial (or boundary) conditions for y_n, the expansion (M11.3.4.3) should be taken into account.

The success in the application of this method is primarily determined by the possibility of constructing a solution of equation (M11.3.4.4) for the leading term y_0. It is significant to note that the other terms y_n with $n \geq 1$ are governed by linear equations with homogeneous initial conditions.

Example 1. The Duffing equation

$$y''_{tt} + y + \varepsilon y^3 = 0 \tag{M11.3.4.6}$$

with initial conditions

$$y(0) = a, \quad y'_t(0) = 0$$

describes the motion of a cubic oscillator, i.e., oscillations of a point mass on a nonlinear spring. Here, y is the deviation of the point mass from the equilibrium and t is dimensionless time.

For $\varepsilon \to 0$, an approximate solution of the problem is sought in the form of the asymptotic expansion (M11.3.4.3). We substitute (M11.3.4.3) into equation (M11.3.4.6) and initial conditions and expand in powers of ε. On equating the coefficients of like powers of the small parameter to zero, we obtain the following problems for y_0 and y_1:

$$y''_0 + y_0 = 0, \qquad y_0(0) = a, \quad y'_0(0) = 0;$$

$$y''_1 + y_1 = -y_0^3, \qquad y_1(0) = 0, \quad y'_1(0) = 0.$$

The solution of the problem for y_0 is given by

$$y_0 = a\cos t.$$

Substituting this expression into the equation for y_1 and taking into account the identity $\cos^3 t = \frac{1}{4}\cos 3t + \frac{3}{4}\cos t$, we obtain

$$y''_1 + y_1 = -\tfrac{1}{4}a^3(\cos 3t + 3\cos t), \qquad y_1(0) = 0, \quad y'_1(0) = 0.$$

Integrating yields

$$y_1 = -\tfrac{3}{8}a^3 t\sin t + \tfrac{1}{32}a^3(\cos 3t - 3\cos t).$$

Thus the two-term solution of the original problem is given by

$$y = a\cos t + \varepsilon a^3\bigl[-\tfrac{3}{8}t\sin t + \tfrac{1}{32}(\cos 3t - 3\cos t)\bigr] + O(\varepsilon^2).$$

Remark 1. The term $t\sin t$ causes $y_1/y_0 \to \infty$ as $t \to \infty$. For this reason, the solution obtained is unsuitable at large times. It can only be used for $\varepsilon t \ll 1$; this results from the condition of applicability of the expansion, $y_0 \gg \varepsilon y_1$.

This circumstance is typical of the method of regular series expansions with respect to the small parameter; in other words, the expansion becomes unsuitable at large values of the independent variable. Methods that allow avoiding this difficulty are discussed below.

Remark 2. Growing terms as $t \to \infty$, like $t\sin t$, that narrow down the domain of applicability of asymptotic expansions are called *secular*.

► **Method of scaled parameters (Lindstedt–Poincaré method).** This method is usually used for finding periodic solutions to equations of the form

$$y''_{tt} + \omega_0 y = \varepsilon f(y, y'_t), \qquad \text{(M11.3.4.7)}$$

where $\varepsilon \ll 1$.

A solutions is sought in the form

$$t = z\Bigl(1 + \sum_{k=0}^{n}\varepsilon^k\omega_k\Bigr), \qquad y(t) = \sum_{k=0}^{n}\varepsilon^k y_k(z). \qquad \text{(M11.3.4.8)}$$

The constants ω_k and functions $y_k(z)$ are determined; it is assumed that $y_{k+1}/y_k = O(1)$. By choosing appropriate ω_k, one removes the secular terms from the solution.

Example 2. Consider the Duffing equation (M11.3.4.6) once again. Following (M11.3.4.8), one performs the change of variable

$$t = z(1 + \varepsilon\omega_1 + \cdots)$$

to obtain

$$y''_{zz} + (1 + \varepsilon\omega_1 + \cdots)^2(y + \varepsilon y^3) = 0. \qquad \text{(M11.3.4.9)}$$

The solution is sought in the series form (M11.3.4.8), $y = y_0(z) + \varepsilon y_1(z) + \cdots$. Substituting it into equation (M11.3.4.9) and matching the coefficients of like powers of ε, one arrives at the following system of equations for two leading terms of the series:

$$y_0'' + y_0 = 0, \qquad \text{(M11.3.4.10)}$$

$$y_1'' + y_1 = -y_0^3 - 2\omega_1 y_0, \qquad \text{(M11.3.4.11)}$$

where the prime denotes differentiation with respect to z.

The general solution of equation (M11.3.4.10) is given by

$$y_0 = a\cos(z + b), \qquad \text{(M11.3.4.12)}$$

where a and b are constants of integration. Taking into account (M11.3.4.12) and rearranging terms, we reduce equation (M11.3.4.11) to

$$y_1'' + y_1 = -\tfrac{1}{4}a^3\cos\bigl[3(z + b)\bigr] - 2a\bigl(\tfrac{3}{8}a^2 + \omega_1\bigr)\cos(z + b). \qquad \text{(M11.3.4.13)}$$

For $\omega_1 \neq -\frac{3}{8}a^2$, the particular solution of equation (M11.3.4.13) contains a secular term proportional to $z\cos(z + b)$. In this case, the condition of applicability of the expansion, $y_1/y_0 = O(1)$, cannot be satisfied at sufficiently large z. For this condition to be met, one should set

$$\omega_1 = -\tfrac{3}{8}a^2. \qquad \text{(M11.3.4.14)}$$

In this case, the solution of equation (M11.3.4.13) is given by

$$y_1 = \tfrac{1}{32}a^3\cos\bigl[3(z + b)\bigr]. \qquad \text{(M11.3.4.15)}$$

Subsequent terms of the expansion can be found likewise.

With (M11.3.4.12), (M11.3.4.14), and (M11.3.4.15), we obtain a solution of the Duffing equation in the form

$$y = a\cos(\omega t + b) + \tfrac{1}{32}\varepsilon a^3\cos\bigl[3(\omega t + b)\bigr] + O(\varepsilon^2),$$

$$\omega = \bigl[1 - \tfrac{3}{8}\varepsilon a^2 + O(\varepsilon^2)\bigr]^{-1} = 1 + \tfrac{3}{8}\varepsilon a^2 + O(\varepsilon^2).$$

► **Averaging method (Van der Pol–Krylov–Bogolyubov scheme).** The averaging method involves two stages. First, the second-order nonlinear equation (M11.3.4.7) is reduced with the transformation

$$y = a\cos\varphi, \quad y'_t = -\omega_0 a\sin\varphi, \qquad \text{where} \quad a = a(t), \quad \varphi = \varphi(t),$$

to an equivalent system of two first-order differential equations:

$$\begin{aligned} a'_t &= -\frac{\varepsilon}{\omega_0} f(a\cos\varphi, -\omega_0 a\sin\varphi)\sin\varphi, \\ \varphi'_t &= \omega_0 - \frac{\varepsilon}{\omega_0 a} f(a\cos\varphi, -\omega_0 a\sin\varphi)\cos\varphi. \end{aligned} \tag{M11.3.4.16}$$

The right-hand sides of equations (M11.3.4.16) are periodic in φ, with the amplitude a being a slow-varying function of time t. The amplitude and the oscillation character are changing little during the time the phase φ changes by 2π.

At the second stage, the right-hand sides of equations (M11.3.4.16) are being averaged with respect to φ. This procedure results in an approximate system of equations:

$$\begin{aligned} a'_t &= -\frac{\varepsilon}{\omega_0} f_{\rm s}(a), \\ \varphi'_t &= \omega_0 - \frac{\varepsilon}{\omega_0 a} f_{\rm c}(a), \end{aligned} \tag{M11.3.4.17}$$

where

$$\begin{aligned} f_{\rm s}(a) &= \frac{1}{2\pi}\int_0^{2\pi} \sin\varphi\, f(a\cos\varphi, -\omega_0 a\sin\varphi)\,d\varphi, \\ f_{\rm c}(a) &= \frac{1}{2\pi}\int_0^{2\pi} \cos\varphi\, f(a\cos\varphi, -\omega_0 a\sin\varphi)\,d\varphi. \end{aligned}$$

System (M11.3.4.17) is substantially simpler than the original system (M11.3.4.16)—the first equation in (M11.3.4.17), for the oscillation amplitude a, is a separable equation and, hence, can readily be integrated; then the second equation in (M11.3.4.17) can also be integrated.

M11.3.5. Galerkin Method and Its Modifications (Projection Methods)

► **General form of an approximate solution.** Consider a boundary value problem for the equation

$$\mathfrak{F}[y] - f(x) = 0 \tag{M11.3.5.1}$$

with linear homogeneous boundary conditions* at the points $x = x_1$ and $x = x_2$ ($x_1 \le x \le x_2$). Here, $\mathfrak{F}$ is a linear or nonlinear differential operator of the second order (or a higher order operator); $y = y(x)$ is the unknown function and $f = f(x)$ is a given function. It is assumed that $\mathfrak{F}[0] = 0$.

Let us choose a sequence of linearly independent functions (called *basis functions*)

$$\varphi = \varphi_n(x) \qquad (n = 1,\ 2,\ \dots,\ N) \tag{M11.3.5.2}$$

---

* Nonhomogeneous boundary conditions can be reduced to homogeneous ones by the change of variable $z = A_2x^2 + A_1x + A_0 + y$ (the constants A_2, A_1, and A_0 are selected using the method of undetermined coefficients).

satisfying the same boundary conditions as $y = y(x)$. According to all methods that will be considered below, an approximate solution of equation (M11.3.5.1) is sought as a linear combination

$$y_N = \sum_{n=1}^{N} A_n \varphi_n(x), \qquad \text{(M11.3.5.3)}$$

with the unknown coefficients A_n to be found in the process of solving the problem.

The finite sum (M11.3.5.3) is called an *approximation function*. The remainder term R_N obtained after the finite sum has been substituted into the left-hand side of equation (M11.3.5.1),

$$R_N = \mathfrak{F}[y_N] - f(x). \qquad \text{(M11.3.5.4)}$$

If the remainder R_N is identically equal to zero, then the function y_N is the exact solution of equation (M11.3.5.1). In general, $R_N \not\equiv 0$.

► **Galerkin method.** In order to find the coefficients A_n in (M11.3.5.3), consider another sequence of linearly independent functions

$$\psi = \psi_k(x) \qquad (k = 1, 2, \dots, N). \qquad \text{(M11.3.5.5)}$$

Let us multiply both sides of (M11.3.5.4) by ψ_k and integrate the resulting relation over the region $V = \{x_1 \le x \le x_2\}$, in which we seek the solution of equation (M11.3.5.1). Next, we equate the corresponding integrals to zero (for the exact solutions, these integrals are equal to zero). Thus, we obtain the following system of algebraic equations for the unknown coefficients A_n:

$$\int_{x_1}^{x_2} \psi_k R_N \, dx = 0 \qquad (k = 1, 2, \dots, N). \qquad \text{(M11.3.5.6)}$$

Relations (M11.3.5.6) mean that the approximation function (M11.3.5.3) satisfies equation (M11.3.5.1) "on the average" (i.e., in the integral sense) with weights ψ_k. Introducing the scalar product $\langle g, h\rangle = \int_{x_1}^{x_2} gh\,dx$ of arbitrary functions g and h, we can consider equations (M11.3.5.6) as the condition of orthogonality of the remainder R_N to all weight functions ψ_k.

The Galerkin method can be applied not only to boundary value problems, but also to eigenvalue problems (in the latter case, one takes $f = \lambda y$ and seeks eigenfunctions y_n, together with eigenvalues λ_n).

Mathematical justification of the Galerkin method for specific boundary value problems can be found in the literature listed at the end of Chapter M11. Below we describe some other methods that are in fact special cases of the Galerkin method.

Remark. Most often, one takes suitable sequences of polynomials or trigonometric functions as $\varphi_n(x)$ in the approximation function (M11.3.5.3).

► **Bubnov–Galerkin method, the moment method, the least squares method.**

1°. The sequences of functions (M11.3.5.2) and (M11.3.5.5) in the Galerkin method can be chosen arbitrarily. In the case of equal functions,

$$\varphi_k(x) = \psi_k(x) \qquad (k = 1, 2, \dots, N), \qquad \text{(M11.3.5.7)}$$

the method is often called the *Bubnov–Galerkin method*.

2°. The *moment method* is the Galerkin method with the weight functions (M11.3.5.5) being powers of x,

$$\psi_k = x^k. \tag{M11.3.5.8}$$

3°. Sometimes, the functions ψ_k are expressed in terms of φ_k by the relations

$$\psi_k = \mathfrak{F}[\varphi_k] \qquad (k = 1,\, 2,\, \ldots),$$

where $\mathfrak{F}$ is the differential operator of equation (M11.3.5.1). This version of the Galerkin method is called the *least squares method*.

► **Collocation method.** In the collocation method, one chooses a sequence of points x_k, $k = 1, \ldots, N$, and imposes the condition that the remainder (M11.3.5.4) be zero at these points,

$$R_N = 0 \quad \text{at} \quad x = x_k \qquad (k = 1, \ldots, N). \tag{M11.3.5.9}$$

When solving a specific problem, the points x_k, at which the remainder R_N is set equal to zero, are regarded as most significant. The number of collocation points N is taken equal to the number of the terms of the series (M11.3.5.3). This allows one to obtain a complete system of algebraic equations for the unknown coefficients A_n (for linear boundary value problems, this algebraic system is linear).

Note that the collocation method is a special case of the Galerkin method with the sequence (M11.3.5.5) consisting of the Dirac delta functions:

$$\psi_k = \delta(x - x_k).$$

In the collocation method, there is no need to calculate integrals, and this essentially simplifies the procedure of solving nonlinear problems (although usually this method yields less accurate results than other modifications of the Galerkin method).

Example. Consider the boundary value problem for the linear second-order ordinary differential equation with variable coefficients

$$y''_{xx} + g(x)y - f(x) = 0 \tag{M11.3.5.10}$$

subject to the boundary conditions of the first kind

$$y(-1) = y(1) = 0. \tag{M11.3.5.11}$$

Assume that the coefficients of equation (M11.3.5.10) are smooth even functions, so that $f(x) = f(-x)$ and $g(x) = g(-x)$. We use the collocation method for the approximate solution of problem (M11.3.5.10)–(M11.3.5.11).

1°. Take the polynomials

$$y_n(x) = x^{2n-2}(1 - x^2), \qquad n = 1,\, 2,\, \ldots\, N,$$

as the basis functions; they satisfy the boundary conditions (M11.3.5.11), $y_n(\pm 1) = 0$.

Let us consider three collocation points

$$x_1 = -\sigma, \quad x_2 = 0, \quad x_3 = \sigma \qquad (0 < \sigma < 1) \tag{M11.3.5.12}$$

and confine ourselves to two basis functions ($N = 2$), so that the approximation function is taken in the form

$$y(x) = A_1(1 - x^2) + A_2x^2(1 - x^2). \tag{M11.3.5.13}$$

Substituting (M11.3.5.13) into the left-hand side of equation (M11.3.5.10) yields the remainder

$$R(x) = A_1\bigl[-2 + (1 - x^2)g(x)\bigr] + A_2\bigl[2 - 12x^2 + x^2(1 - x^2)g(x)\bigr] - f(x).$$

It must vanish at the collocation points (M11.3.5.12). Taking into account the properties $f(\sigma) = f(-\sigma)$ and $g(\sigma) = g(-\sigma)$, we obtain two linear algebraic equations for the coefficients A_1 and A_2:

$$\begin{gathered} A_1\bigl[-2 + g(0)\bigr] + 2A_2 - f(0) = 0 \qquad (\text{at } x = 0),\\ A_1\bigl[-2 + (1 - \sigma^2)g(\sigma)\bigr] + A_2\bigl[2 - 12\sigma^2 + \sigma^2(1 - \sigma^2)g(\sigma)\bigr] - f(\sigma) = 0 \qquad (\text{at } x = \pm\sigma). \end{gathered} \tag{M11.3.5.14}$$

2°. To be specific, let us take the following functions appearing in equation (M11.3.5.10):

$$f(x) = -1, \quad g(x) = 1 + x^2. \qquad \text{(M11.3.5.15)}$$

On solving the corresponding system of algebraic equations (M11.3.5.14), we find the coefficients

$$A_1 = \frac{\sigma^4 + 11}{\sigma^4 + 2\sigma^2 + 11}, \quad A_2 = -\frac{\sigma^2}{\sigma^4 + 2\sigma^2 + 11}. \qquad \text{(M11.3.5.16)}$$

In Fig. M11.2, the solid line depicts the numerical solution to problem (M11.3.5.10)–(M11.3.5.11), with the functions (M11.3.5.15), obtained by the shooting method (see Subsection M11.3.6). The dashed lines 1 and 2 show the approximate solutions obtained by the collocation method using the formulas (M11.3.5.13), (M11.3.5.16) with $\sigma = \frac{1}{2}$ (equidistant points) and $\sigma = \frac{\sqrt{2}}{2}$ (Chebyshev points*), respectively. It is evident that both cases provide good agreement between the approximate and numerical solutions; the use of Chebyshev points gives a more accurate result.

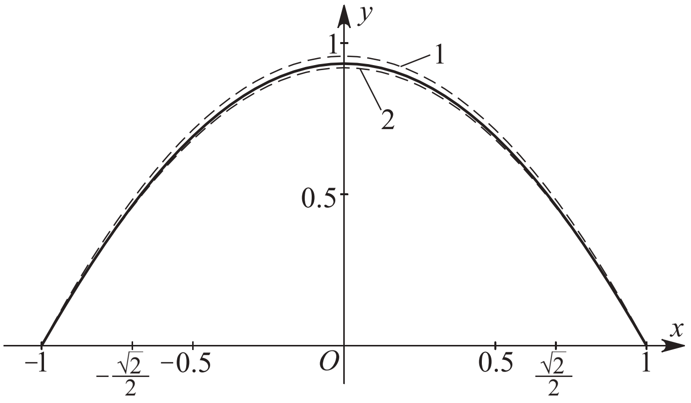

Figure M11.2. Comparison of the numerical solution of problem (M11.3.5.10), (M11.3.5.11), (M11.3.5.15) with the approximate analytical solution (M11.3.5.13), (M11.3.5.16) obtained with the collocation method.

► **Method of partitioning the domain.** The domain $V = \{x_1 \le x \le x_2\}$ is split into N subdomains: $V_k = \{x_{k1} \le x \le x_{k2}\}$, $k = 1, \ldots, N$. In this method, the weight functions are chosen as follows:

$$\psi_k(x) = \begin{cases} 1 & \text{for } x \in V_k, \\ 0 & \text{for } x \notin V_k. \end{cases}$$

The subdomains V_k are chosen according to the specific properties of the problem under consideration and can generally be arbitrary (the union of all subdomains V_k may differ from the domain V, and some V_k and V_m may overlap).

► **Least squared error method.** Sometimes, in order to find the coefficients A_n of the approximation function (M11.3.5.3), one uses the least squared error method based on the minimization of the functional:

$$\Phi = \int_{x_1}^{x_2} R_N^2 \, dx \to \min. \qquad \text{(M11.3.5.17)}$$

For given functions φ_n in (M11.3.5.3), the integral Φ is a function with respect to the coefficients A_n. The corresponding necessary conditions of minimum in (M11.3.5.17) have the form

$$\frac{\partial \Phi}{\partial A_n} = 0 \qquad (n = 1, \ldots, N).$$

This is a system of algebraic equations for the coefficients A_n.

---

* Chebyshev nodes (points) are generally defined by $x_i = \cos\Bigl(\frac{2i-1}{2m}\pi\Bigr)$, $i = 1, \ldots, m$. In this case, $m = 2$.

M11.3.6. Iteration and Numerical Methods

► **Method of successive approximations (Cauchy problem).** The method of successive approximations is implemented in two steps. First, the Cauchy problem

$$y''_{xx} = f(x, y, y'_x) \qquad \text{(equation)}, \qquad \text{(M11.3.6.1)}$$

$$y(x_0) = y_0, \quad y'_x(x_0) = y'_0 \qquad \text{(initial conditions)} \qquad \text{(M11.3.6.2)}$$

is reduced to an equivalent system of integral equations by the introduction of the new variable $u(x) = y'_x$. These integral equations have the form

$$u(x) = y'_0 + \int_{x_0}^{x} f\bigl(t, y(t), u(t)\bigr)\,dt, \qquad y(x) = y_0 + \int_{x_0}^{x} u(t)\,dt. \qquad \text{(M11.3.6.3)}$$

Then the solution of system (M11.3.6.3) is sought by means of successive approximations defined by the following recurrence formulas:

$$u_{n+1}(x) = y'_0 + \int_{x_0}^{x} f\bigl(t, y_n(t), u_n(t)\bigr)\,dt, \qquad y_{n+1}(x) = y_0 + \int_{x_0}^{x} u_n(t)\,dt; \qquad n = 0,\ 1,\ 2,\ \dots$$

As the initial approximation, one can take $y_0(x) = y_0$ and $u_0(x) = y'_0$.

► **Runge–Kutta method (Cauchy problem).** For the numerical integration of the Cauchy problem (M11.3.6.1)–(M11.3.6.2), one often uses the Runge–Kutta method.

Let Δx be sufficiently small. We introduce the following notation:

$$x_k = x_0 + k\Delta x, \quad y_k = y(x_k), \quad y'_k = y'_x(x_k), \quad f_k = f(x_k, y_k, y'_k); \qquad k = 0,\ 1,\ 2,\ \dots$$

The desired values y_k and y'_k are successively found by the formulas

$$y_{k+1} = y_k + y'_k\Delta x + \tfrac{1}{6}(f_1 + f_2 + f_3)(\Delta x)^2,$$

$$y'_{k+1} = y'_k + \tfrac{1}{6}(f_1 + 2f_2 + 2f_3 + f_4)\Delta x,$$

where

$$f_1 = f\bigl(x_k,\ y_k,\ y'_k\bigr),$$

$$f_2 = f\bigl(x_k + \tfrac{1}{2}\Delta x,\ y_k + \tfrac{1}{2}y'_k\Delta x,\ y'_k + \tfrac{1}{2}f_1\Delta x\bigr),$$

$$f_3 = f\bigl(x_k + \tfrac{1}{2}\Delta x,\ y_k + \tfrac{1}{2}y'_k\Delta x + \tfrac{1}{4}f_1(\Delta x)^2,\ y'_k + \tfrac{1}{2}f_2\Delta x\bigr),$$

$$f_4 = f\bigl(x_k + \Delta x,\ y_k + y'_k\Delta x + \tfrac{1}{2}f_2(\Delta x)^2,\ y'_k + f_3\Delta x\bigr).$$

In practice, the step Δx is determined in the same way as for first-order equations (see Remark 2 in Subsection M11.1.7).

► **Shooting method (boundary value problems).** In order to solve the boundary value problem for equation (M11.3.6.1) with the boundary conditions

$$y(x_1) = y_1, \qquad y(x_2) = y_2, \qquad \text{(M11.3.6.4)}$$

one considers an auxiliary Cauchy problem for equation (M11.3.6.1) with the initial conditions

$$y(x_1) = y_1, \qquad y'_x(x_1) = a. \qquad \text{(M11.3.6.5)}$$

(The solution of this Cauchy problem can be obtained by the Runge–Kutta method or some other numerical method.) The parameter a is chosen so that the value of the solution

$y = y(x, a)$ at the point $x = x_2$ coincides with the value required by the second boundary condition in (M11.3.6.4):

$$y(x_2, a) = y_2.$$

First, one finds an a_1 and an a_2 ($a_1 < a_2$) such that

$$[y(x_2, a_1) - y_2][y(x_2, a_2) - y_2] < 0.$$

This implies that the desired a in (M11.3.6.5) belongs to the interval (a_1, a_2). Then a sequence of numbers a_n such that

$$[y(x_2, a_{n-1}) - y_2][y(x_2, a_n) - y_2] < 0$$

is determined numerically, for example, by using the bisection method. The desired a is obtained as: $a = \lim\limits_{n\to\infty} a_n$.

In a similar way one constructs the solution of the boundary value problem with mixed boundary conditions

$$y(x_1) = y_1, \qquad y'_x(x_2) + ky(x_2) = y_2. \tag{M11.3.6.6}$$

In this case, one also considers the auxiliary Cauchy problem (M11.3.6.1), (M11.3.6.5). The parameter a is chosen so that the solution $y = y(x, a)$ satisfies the second boundary condition in (M11.3.6.6) at the point $x = x_2$.

M11.4. Linear Equations of Arbitrary Order and Linear Systems of Equations

M11.4.1. Linear Equations with Constant Coefficients

► **Homogeneous linear equations.** An nth-order homogeneous linear equation with constant coefficients has the general form

$$y^{(n)}_x + a_{n-1} y^{(n-1)}_x + \cdots + a_1 y'_x + a_0 y = 0. \tag{M11.4.1.1}$$

The general solution of this equation is determined by the roots of the characteristic equation

$$P(\lambda) = 0, \qquad \text{where} \quad P(\lambda) = \lambda^n + a_{n-1}\lambda^{n-1} + \cdots + a_1\lambda + a_0. \tag{M11.4.1.2}$$

The following cases are possible:

1°. All roots $\lambda_1, \lambda_2, \ldots, \lambda_n$ of the characteristic equation (M11.4.1.2) are real and distinct. Then the general solution of the homogeneous linear differential equation (M11.4.1.1) has the form

$$y = C_1 \exp(\lambda_1 x) + C_2 \exp(\lambda_2 x) + \cdots + C_n \exp(\lambda_n x).$$

2°. There are m equal real roots $\lambda_1 = \lambda_2 = \cdots = \lambda_m$ ($m \le n$), and the other roots are real and distinct. In this case, the general solution is given by

$$\begin{aligned} y &= \exp(\lambda_1 x)(C_1 + C_2 x + \cdots + C_m x^{m-1}) \\ &\quad + C_{m+1} \exp(\lambda_{m+1} x) + C_{m+2} \exp(\lambda_{m+2} x) + \cdots + C_n \exp(\lambda_n x). \end{aligned}$$

3°. There are m equal complex conjugate roots $\lambda_{1,2} = \alpha \pm i\beta$ ($2m \le n$), and the other roots are real and distinct. In this case, the general solution is

$$\begin{aligned} y &= \exp(\alpha x)\cos(\beta x)(A_1 + A_2 x + \cdots + A_m x^{m-1}) \\ &\quad + \exp(\alpha x)\sin(\beta x)(B_1 + B_2 x + \cdots + B_m x^{m-1}) \\ &\quad + C_{2m+1} \exp(\lambda_{2m+1} x) + C_{2m+2} \exp(\lambda_{2m+2} x) + \cdots + C_n \exp(\lambda_n x), \end{aligned}$$

where $A_1, \ldots, A_m, B_1, \ldots, B_m, C_{2m+1}, \ldots, C_n$ are arbitrary constants.

4°. In the general case, where there are r different roots $\lambda_1, \lambda_2, \ldots, \lambda_r$ of multiplicities $m_1, m_2, \ldots, m_r$, respectively, the left-hand side of the characteristic equation (M11.4.1.2) can be represented as the product

$$P(\lambda) = (\lambda - \lambda_1)^{m_1}(\lambda - \lambda_2)^{m_2} \ldots (\lambda - \lambda_r)^{m_r},$$

where $m_1 + m_2 + \cdots + m_r = n$. The general solution of the original equation is given by the formula

$$y = \sum_{k=1}^{r} \exp(\lambda_k x)(C_{k,0} + C_{k,1}x + \cdots + C_{k,m_k-1}x^{m_k-1}),$$

where $C_{k,l}$ are arbitrary constants.

If the characteristic equation (M11.4.1.2) has complex conjugate roots $\lambda_s = \alpha_s + i\beta_s$ and $\lambda_{s+1} = \alpha_s - i\beta_s$, then in the above solution, the corresponding functions $\exp(\lambda_s x)$ and $\exp(\lambda_{s+1}x)$ should be replaced with $\exp(\alpha_s x)\cos(\beta_s x)$ and $\exp(\alpha_s x)\sin(\beta_s x)$, respectively, in a similar way to that in Item 3°.

Example 1. Find the general solution of the linear third-order equation

$$y''' + ay'' - y' - ay = 0.$$

Its characteristic equation is $\lambda^3 + a\lambda^2 - \lambda - a = 0$, or, in factorized form,

$$(\lambda + a)(\lambda - 1)(\lambda + 1) = 0.$$

Depending on the value of the parameter a, three cases are possible.

1. Case $a \neq \pm 1$. There are three different roots, $\lambda_1 = -a$, $\lambda_2 = -1$, and $\lambda_3 = 1$. The general solution of the differential equation is expressed as $y = C_1e^{-ax} + C_2e^{-x} + C_3e^{x}$.

2. Case $a = 1$. There is a double root, $\lambda_1 = \lambda_2 = -1$, and a simple root, $\lambda_3 = 1$. The general solution of the differential equation has the form $y = (C_1 + C_2x)e^{-x} + C_3e^{x}$.

3. Case $a = -1$. There is a double root, $\lambda_1 = \lambda_2 = 1$, and a simple root, $\lambda_3 = -1$. The general solution of the differential equation is expressed as $y = (C_1 + C_2x)e^{x} + C_3e^{-x}$.

Example 2. Consider the linear fourth-order equation

$$y''''_{xxxx} - y = 0.$$

Its characteristic equation, $\lambda^4 - 1 = 0$, has four distinct roots, two real and two pure imaginary,

$$\lambda_1 = 1, \quad \lambda_2 = -1, \quad \lambda_3 = i, \quad \lambda_4 = -i.$$

Therefore, the general solution of the equation in question has the form (see Item 3°)

$$y = C_1e^{x} + C_2e^{-x} + C_3\sin x + C_4\cos x.$$

► Nonhomogeneous linear equations. Forms of particular solutions.

1°. An nth-order nonhomogeneous linear equation with constant coefficients has the general form

$$y_x^{(n)} + a_{n-1}y_x^{(n-1)} + \cdots + a_1y'_x + a_0y = f(x). \tag{M11.4.1.3}$$

The general solution of this equation is the sum of the general solution of the corresponding homogeneous equation with $f(x) \equiv 0$ (see equation M11.4.1.1) and any particular solution of the nonhomogeneous equation (M11.4.1.3).

If the roots $\lambda_1, \lambda_2, \ldots, \lambda_n$ of the characteristic equation (M11.4.1.2) are all real and distinct, equation (M11.4.1.3) has the general solution:

$$y = \sum_{\nu=1}^{n} C_\nu e^{\lambda_\nu x} + \sum_{\nu=1}^{n} \frac{e^{\lambda_\nu x}}{P'_\lambda(\lambda_\nu)} \int f(x)e^{-\lambda_\nu x}\,dx. \tag{M11.4.1.4}$$

In the general case, if the characteristic equation (M11.4.1.2) has complex and/or multiple roots, the solution to equation (M11.4.1.3) can be constructed using formula (M11.4.2.5).

TABLE M11.4
Forms of particular solutions to the nonhomogeneous linear equation with constant coefficients $y_x^{(n)} + a_{n-1}y_x^{(n-1)} + \cdots + a_1 y'_x + a_0 y = f(x)$, that correspond to some special forms of the function $f(x)$.

Form of the function $f(x)$	Roots of the characteristic equation $\lambda^n + a_{n-1}\lambda^{n-1} + \cdots + a_1\lambda + a_0 = 0$	Form of particular solution
$P_m(x)$	Zero is not a root of the characteristic equation (i.e., $a_0 \neq 0$)	$\widetilde{P}_m(x)$
	Zero is a root of the characteristic equation (multiplicity r)	$x^r \widetilde{P}_m(x)$
$P_m(x)e^{\alpha x}$ (α is a real constant)	α is not a root of the characteristic equation	$\widetilde{P}_m(x)e^{\alpha x}$
	α is a root of the characteristic equation (multiplicity r)	$x^r \widetilde{P}_m(x)e^{\alpha x}$
$P_m(x)\cos\beta x + Q_k(x)\sin\beta x$	$i\beta$ is not a root of the characteristic equation	$\widetilde{P}_\nu(x)\cos\beta x + \widetilde{Q}_\nu(x)\sin\beta x$
	$i\beta$ is a root of the characteristic equation (multiplicity r)	$x^r[\widetilde{P}_\nu(x)\cos\beta x + \widetilde{Q}_\nu(x)\sin\beta x]$
$[P_m(x)\cos\beta x + Q_k(x)\sin\beta x]e^{\alpha x}$	$\alpha + i\beta$ is not a root of the characteristic equation	$[\widetilde{P}_\nu(x)\cos\beta x + \widetilde{Q}_\nu(x)\sin\beta x]e^{\alpha x}$
	$\alpha + i\beta$ is a root of the characteristic equation (multiplicity r)	$x^r[\widetilde{P}_\nu(x)\cos\beta x + \widetilde{Q}_\nu(x)\sin\beta x]e^{\alpha x}$
Notation: P_m and Q_k are polynomials of degrees m and k with given coefficients; $\widetilde{P}_m$, $\widetilde{P}_\nu$, and $\widetilde{Q}_\nu$ are polynomials of degrees m and ν whose coefficients are determined by substituting the particular solution into the basic equation; $\nu = \max\{m, k\}$; and α and β are real numbers, $i^2 = -1$.		

2°. Table M11.4 lists the forms of particular solutions corresponding to some special forms of functions on the right-hand side of the linear nonhomogeneous equation.

3°. Consider the Cauchy problem for equation (M11.4.1.3) subject to the homogeneous initial conditions

$$y(0) = y'_x(0) = \cdots = y_x^{(n-1)}(0) = 0. \qquad \text{(M11.4.1.5)}$$

Let $y(x)$ be the solution of problem (M11.4.1.3), (M11.4.1.5) for arbitrary $f(x)$ and let $u(x)$ be the solution of the auxiliary, simpler problem (M11.4.1.3), (M11.4.1.5) with $f(x) \equiv 1$, so that $u(x) = y(x)|_{f(x)\equiv 1}$. Then the formula

$$y(x) = \int_0^x f(t)u'_x(x-t)\,dt$$

holds. It is called the *Duhamel integral*.

► **Solution of the Cauchy problem using the Laplace transform.** Consider the Cauchy problem for equation (M11.4.1.3) with arbitrary initial conditions

$$y(0) = y_0, \quad y'_x(0) = y_1, \quad \ldots, \quad y_x^{(n-1)}(0) = y_{n-1}, \qquad \text{(M11.4.1.6)}$$

where $y_0, y_1, \ldots, y_{n-1}$ are given constants.

Problem (M11.4.1.3), (M11.4.1.6) can be solved using the Laplace transform based on the formulas (for details, see Section M10.2)

$$\widetilde{y}(p) = \mathfrak{L}\bigl\{y(x)\bigr\}, \quad \widetilde{f}(p) = \mathfrak{L}\bigl\{f(x)\bigr\}, \quad \text{where} \quad \mathfrak{L}\bigl\{f(x)\bigr\} \equiv \int_0^\infty e^{-px} f(x)\,dx.$$

To this end, let us multiply equation (M11.4.1.3) by e^{-px} and then integrate with respect to x from zero to infinity. Taking into account the formula

$$\mathfrak{L}\bigl\{y_x^{(n)}(x)\bigr\} = p^n \widetilde{y}(p) - \sum_{k=1}^{n} p^{n-k} y_x^{(k-1)}(+0)$$

and the initial conditions (M11.4.1.6), we arrive at a linear algebraic equation for the transform $\widetilde{y}(p)$:

$$P(p)\widetilde{y}(p) - Q(p) = \widetilde{f}(p), \tag{M11.4.1.7}$$

where

$$P(p) = p^n + a_{n-1}p^{n-1} + \cdots + a_1 p + a_0, \qquad Q(p) = b_{n-1}p^{n-1} + \cdots + b_1 p + b_0,$$
$$b_k = y_{n-k-1} + a_{n-1}y_{n-k-2} + \cdots + a_{k+2}y_1 + a_{k+1}y_0, \qquad k = 0,\ 1,\ \ldots,\ n-1.$$

The polynomial $P(p)$ coincides with the characteristic polynomial (M11.4.1.2) at $\lambda = p$.

The solution of equation (M11.4.1.7) is given by the formula

$$\widetilde{y}(p) = \frac{\widetilde{f}(p) + Q(p)}{\widetilde{P}(p)}. \tag{M11.4.1.8}$$

On applying the Laplace inversion formula (see in Section M10.2) to (M11.4.1.8), we obtain a solution to problem (M11.4.1.3), (M11.4.1.6) in the form

$$y(x) = \frac{1}{2\pi i} \int_{c-i\infty}^{c+i\infty} \frac{\widetilde{f}(p) + Q(p)}{\widetilde{P}(p)} e^{px}\,dp. \tag{M11.4.1.9}$$

Since the transform $\widetilde{y}(p)$ (M11.4.1.8) is a rational function, the inverse Laplace transform (M11.4.1.9) can be obtained using the formulas from Subsection M10.2.2 or the tables of Section S2.2.

Remark. In practice, the solution method for the Cauchy problem based on the Laplace transform leads to the solution faster than the direct application of general formulas like (M11.4.1.4), where one has to determine the coefficients $C_1, \ldots, C_n$.

Example 3. Consider the following Cauchy problem for a homogeneous fourth-order equation:

$$y''''_{xxxx} + a^4 y = 0; \qquad y(0) = y'_x(0) = y'''_{xxx}(0) = 0, \quad y''_{xx}(0) = b.$$

The Laplace transform reduces this problem to a linear algebraic equation for $\widetilde{y}(p)$: $(p^4 + a^4)\widetilde{y}(p) - bp = 0$. It follows that

$$\widetilde{y}(p) = \frac{bp}{p^4 + a^4}.$$

In order to invert this expression, let us use the table of inverse Laplace transforms S2.2.2 (see row 52) and take into account that a constant multiplier can be taken outside the transform operator to obtain the solution to the original Cauchy problem in the form

$$y(x) = \frac{b}{a^2} \sin\Bigl(\frac{ax}{\sqrt{2}}\Bigr) \sinh\Bigl(\frac{ax}{\sqrt{2}}\Bigr).$$

M11.4.2. Linear Equations with Variable Coefficients

► **Homogeneous linear equations. Structure of the general solution.** The general solution of the nth-order homogeneous linear differential equation

$$f_n(x)y_x^{(n)} + f_{n-1}(x)y_x^{(n-1)} + \cdots + f_1(x)y'_x + f_0(x)y = 0 \qquad \text{(M11.4.2.1)}$$

has the form

$$y = C_1y_1(x) + C_2y_2(x) + \cdots + C_ny_n(x), \qquad \text{(M11.4.2.2)}$$

where the functions $y_1(x)$, $y_2(x)$, …, $y_n(x)$ are a fundamental system of solutions (the y_k are linearly independent particular solutions, $y_k \not\equiv 0$); C_1, C_2, …, C_n are arbitrary constants.

► **Utilization of particular solutions for reducing the order of the equation.**

1°. Let $y_1 = y_1(x)$ be a nontrivial particular solution of equation (M11.4.2.1). The substitution

$$y = y_1(x)\int z(x)\,dx$$

results in a linear equation of order $n-1$ for the function $z(x)$.

2°. Let $y_1 = y_1(x)$ and $y_2 = y_2(x)$ be two nontrivial linearly independent solutions of equation (M11.4.2.1). The substitution

$$y = y_1\int y_2w\,dx - y_2\int y_1w\,dx$$

results in a linear equation of order $n-2$ for $w(x)$.

3°. Suppose that m linearly independent solutions $y_1(x)$, $y_2(x)$, …, $y_m(x)$ of equation (M11.4.2.1) are known. Then one can reduce the order of the equation to $n-m$ by successive application of the following procedure. The substitution $y = y_m(x)\int z(x)\,dx$ leads to an equation of order $n-1$ for the function $z(x)$ with known linearly independent solutions:

$$z_1 = \left(\frac{y_1}{y_m}\right)'_x, \quad z_2 = \left(\frac{y_2}{y_m}\right)'_x, \quad \ldots, \quad z_{m-1} = \left(\frac{y_{m-1}}{y_m}\right)'_x.$$

The substitution $z = z_{m-1}(x)\int w(x)\,dx$ yields an equation of order $n-2$. Repeating this procedure m times, we arrive at a homogeneous linear equation of order $n-m$.

► **Wronskian determinant and Liouville formula.** The *Wronskian determinant* (or simply, *Wronskian*) is the function defined as

$$W(x) = \begin{vmatrix} y_1(x) & \cdots & y_n(x) \\ y'_1(x) & \cdots & y'_n(x) \\ \cdots & \cdots & \cdots \\ y_1^{(n-1)}(x) & \cdots & y_n^{(n-1)}(x) \end{vmatrix}, \qquad \text{(M11.4.2.3)}$$

where $y_1(x)$, …, $y_n(x)$ is a fundamental system of solutions of the homogeneous equation (M11.4.2.1); $y_k^{(m)}(x) = \dfrac{d^my_k}{dx^m}$, $m = 1, \ldots, n-1$; $k = 1, \ldots, n$.

The following *Liouville formula* holds:

$$W(x) = W(x_0)\exp\left[-\int_{x_0}^{x}\frac{f_{n-1}(t)}{f_n(t)}\,dt\right],$$

where x_0 is an arbitrary number.

► **Nonhomogeneous linear equations. Construction of the general solution.**

1°. The general nonhomogeneous nth-order linear differential equation has the form

$$f_n(x)y_x^{(n)} + f_{n-1}(x)y_x^{(n-1)} + \cdots + f_1(x)y_x' + f_0(x)y = g(x). \tag{M11.4.2.4}$$

The general solution of the nonhomogeneous equation (M11.4.2.4) is obtained as the sum of the general solution of the corresponding homogeneous equation (M11.4.2.1) and any particular solution of equation (M11.4.2.4).

2°. Let $y_1(x)$, ..., $y_n(x)$ be a fundamental system of solutions of the homogeneous equation (M11.4.2.1), and let $W(x)$ be the Wronskian determinant (M11.4.2.3). Then the general solution of the nonhomogeneous linear equation (M11.4.2.4) can be represented as

$$y = \sum_{\nu=1}^{n} C_\nu y_\nu(x) + \sum_{\nu=1}^{n} y_\nu(x) \int \frac{W_\nu(x)\,dx}{f_n(x)W(x)}, \tag{M11.4.2.5}$$

where $W_\nu(x)$ is the determinant obtained by replacing the νth column of the matrix (M11.4.2.3) by the column vector with the elements $0, 0, \ldots, 0, g$.

3°. *Superposition principle*. A particular solution of a nonhomogeneous linear equation

$$\mathbf{L}[y] = \sum_{k=1}^{m} g_k(x), \qquad \mathbf{L}[y] \equiv f_n(x)y_x^{(n)} + f_{n-1}(x)y_x^{(n-1)} + \cdots + f_1(x)y_x' + f_0(x)y$$

is determined by adding together particular solutions,

$$y = \sum_{k=1}^{m} y_k,$$

of m (simpler) equations,

$$\mathbf{L}[y_k] = g_k(x), \qquad k = 1, 2, \ldots, m,$$

corresponding to respective nonhomogeneous terms in the original equation.

► **Euler equation.** The nonhomogeneous Euler equation has the form

$$x^n y_x^{(n)} + a_{n-1}x^{n-1}y_x^{(n-1)} + \cdots + a_1 x y_x' + a_0 y = f(x).$$

The substitution $x = be^t$ ($b \neq 0$) leads to a constant coefficient linear equation of the form (M11.4.1.3).

Particular solutions of the homogeneous Euler equation [with $f(x) \equiv 0$] are sought in the form $y = x^k$. If all k are real and distinct, its general solution is expressed as

$$y(x) = C_1|x|^{k_1} + C_2|x|^{k_2} + \cdots + C_n|x|^{k_n}.$$

Remark. To a pair of complex conjugate values $k = \alpha \pm i\beta$ there corresponds a pair of particular solutions: $y = |x|^\alpha \sin(\beta|x|)$ and $y = |x|^\alpha \cos(\beta|x|)$.

M11.4.3. Systems of Linear Equations with Constant Coefficients

► Systems of first-order linear homogeneous equations. The general solution.

1°. In general, a homogeneous linear system of first-order ordinary differential equations with constant coefficients has the form

$$\begin{aligned} y_1' &= a_{11}y_1 + a_{12}y_2 + \cdots + a_{1n}y_n,\\ y_2' &= a_{21}y_1 + a_{22}y_2 + \cdots + a_{2n}y_n,\\ &\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\\ y_n' &= a_{n1}y_1 + a_{n2}y_2 + \cdots + a_{nn}y_n, \end{aligned} \qquad \text{(M11.4.3.1)}$$

where a prime stands for the derivative with respect to x. In the sequel, all the coefficients a_{ij} of the system are assumed to be real numbers.

The homogeneous system (M11.4.3.1) has the trivial particular solution $y_1 = y_2 = \cdots = y_n = 0$.

Superposition principle for a homogeneous system: any linear combination of particular solutions of system (M11.4.3.1) is also a solution of this system.

The general solution of the system of differential equations (M11.4.3.1) is the sum of its n linearly independent (nontrivial) particular solutions each multiplied by an arbitrary constant.

Remark. System (M11.4.3.1) can be reduced to a single homogeneous linear constant-coefficient nth-order equation.

2°. For brevity (and clarity), system (M11.4.3.1) is conventionally written in vector-matrix form:

$$\mathbf{y}' = \mathbf{A}\mathbf{y}, \qquad \text{(M11.4.3.2)}$$

where $\mathbf{y} = (y_1, y_2, \dots, y_n)^{\mathrm{T}}$ is the column vector of the unknowns and $\mathbf{A} = (a_{ij})$ is the matrix of the equation coefficients. The superscript T denotes the transpose of a matrix or a vector. So, for example, a row vector is converted into a column vector:

$$(y_1, y_2)^{\mathrm{T}} \equiv \begin{pmatrix} y_1 \\ y_2 \end{pmatrix}.$$

The right-hand side of equation (M11.4.3.2) is the product of the $n \times n$ square matrix **a** by the $n \times 1$ matrix (column vector) **y**.

Let $\mathbf{y}_k = (y_{k1}, y_{k2}, \dots, y_{kn})^{\mathrm{T}}$ be linearly independent particular solutions* of the homogeneous system (M11.4.3.1), where $k = 1, 2, \dots, n$; the first subscript in $y_{km} = y_{km}(x)$ denotes the number of the solution and the second subscript ($m = 1, \dots, n$) indicates the component of the vector solution. Then the general solution of the homogeneous system (M11.4.3.2) is expressed as

$$\mathbf{y} = C_1\mathbf{y}_1 + C_2\mathbf{y}_2 + \cdots + C_n\mathbf{y}_n. \qquad \text{(M11.4.3.3)}$$

A method for the construction of particular solutions that can be used to obtain the general solution by formula (M11.4.3.3) is presented below.

---

* This means that the condition $\det|y_{km}(x)| \neq 0$ holds.

► **Systems of first-order linear homogeneous equations. Particular solutions.** Particular solutions to system (M11.4.3.1) are determined by the roots of the characteristic equation

$$\Delta(\lambda)=0, \quad \text{where} \quad \Delta(\lambda)\equiv\begin{vmatrix} a_{11}-\lambda & a_{12} & \dots & a_{1n} \\ a_{21} & a_{22}-\lambda & \dots & a_{2n} \\ \dots & \dots & \dots & \dots \\ a_{n1} & a_{n2} & \dots & a_{nn}-\lambda \end{vmatrix}. \tag{M11.4.3.4}$$

The following cases are possible:

1°. Let λ be a simple real root of the characteristic equation (M11.4.3.4). The corresponding particular solution of the homogeneous linear system of equations (M11.4.3.1) has the exponential form

$$y_1=A_1e^{\lambda x}, \quad y_2=A_2e^{\lambda x}, \quad \dots, \quad y_n=A_ne^{\lambda x}, \tag{M11.4.3.5}$$

where the coefficients A_1, A_2, …, A_n are determined by solving the associated linear homogeneous system of equations:

$$\begin{aligned} &(a_{11}-\lambda)A_1+a_{12}A_2+\dots+a_{1n}A_n=0,\\ &a_{21}A_1+(a_{22}-\lambda)A_2+\dots+a_{2n}A_n=0,\\ &\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\\ &a_{n1}A_1+a_{n2}A_2+\dots+(a_{nn}-\lambda)A_n=0. \end{aligned} \tag{M11.4.3.6}$$

The solution of this system is unique to within a constant factor.

If all roots of the characteristic equation λ_1, λ_2, …, λ_n are real and distinct, then the general solution of system (M11.4.3.1) has the form

$$\begin{aligned} &y_1=C_1A_{11}e^{\lambda_1x}+C_2A_{12}e^{\lambda_2x}+\dots+C_nA_{1n}e^{\lambda_nx},\\ &y_2=C_1A_{21}e^{\lambda_1x}+C_2A_{22}e^{\lambda_2x}+\dots+C_nA_{2n}e^{\lambda_nx},\\ &\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\\ &y_n=C_1A_{n1}e^{\lambda_1x}+C_2A_{n2}e^{\lambda_2x}+\dots+C_nA_{nn}e^{\lambda_nx}, \end{aligned} \tag{M11.4.3.7}$$

where C_1, C_2, …, C_n are arbitrary constants. The second subscript in A_{mk} indicates a coefficient corresponding to the root λ_k.

2°. For each simple complex root, $\lambda=\alpha+i\beta$, of the characteristic equation (M11.4.3.4), the corresponding particular solution is obtained in the same way as in the simple real root case; the associated coefficients $A_1, A_2, \dots, A_n$ in (M11.4.3.5) will be complex. Separating the real and imaginary parts in (M11.4.3.5) results in two real particular solutions to system (M11.4.3.1); the same two solutions are obtained if one takes the complex conjugate root, $\bar\lambda=\alpha-i\beta$.

3°. Let λ be a real root of the characteristic equation (M11.4.3.4) of multiplicity m. The corresponding particular solution of system (M11.4.3.1) is sought in the form

$$y_1=P_m^1(x)e^{\lambda x}, \quad y_2=P_m^2(x)e^{\lambda x}, \quad \dots, \quad y_n=P_m^n(x)e^{\lambda x}, \tag{M11.4.3.8}$$

where the $P_m^k(x)=\sum\limits_{i=0}^{m-1}B_{ki}x^i$ are polynomials of degree $m-1$. The coefficients of these polynomials result from the substitution of expressions (M11.4.3.8) into equations (M11.4.3.1); after dividing by $e^{\lambda x}$ and collecting like terms, one obtains n equations, each representing a polynomial equated to zero. By equating the coefficients of all resulting polynomials to zero, one arrives at a linear algebraic system of equations for the coefficients B_{ki}; the solution to this system will contain m free parameters.

4°. For a multiple complex root, $\lambda = \alpha + i\beta$, of multiplicity m, the corresponding particular solution is sought, just as in the case of a multiple real root, in the form (M11.4.3.8); here the coefficients B_{ki} of the polynomials $P_m^k(x)$ will be complex. Finally, in order to obtain real solutions of the original system (M11.4.3.1), one separates the real and imaginary parts in formulas (M11.4.3.8), thus obtaining two particular solutions with m free parameters each. The two solutions correspond to the complex conjugate roots $\lambda = \alpha \pm i\beta$.

5°. In the general case, where the characteristic equation (M11.4.3.4) has simple and multiple, real and complex roots (see Items 1°–4°), the general solution to system (M11.4.3.1) is obtained as the sum of all particular solutions multiplied by arbitrary constants.

Example 1. Consider the homogeneous system of two linear differential equations

$$\begin{aligned} y_1' &= y_1 + 4y_2, \\ y_2' &= y_1 + y_2. \end{aligned}$$

The associated characteristic equation,

$$\begin{vmatrix} 1-\lambda & 4 \\ 1 & 1-\lambda \end{vmatrix} = \lambda^2 - 2\lambda - 3 = 0,$$

has distinct real roots:

$$\lambda_1 = 3, \qquad \lambda_2 = -1.$$

The system of algebraic equations (M11.4.3.6) for the solution coefficients becomes

$$\begin{aligned} (1-\lambda)A_1 + 4A_2 &= 0, \\ A_1 + (1-\lambda)A_2 &= 0. \end{aligned} \tag{M11.4.3.9}$$

Substituting the first root, $\lambda = 3$, into system (M11.4.3.9) yields $A_1 = 2A_2$. We can set $A_1 = 2$ and $A_2 = 1$, since the solution is determined to within a constant factor. Thus the first particular solution of the homogeneous system of linear ordinary differential equations (M11.4.3.9) has the form

$$y_1 = 2e^{3x}, \qquad y_2 = e^{3x}. \tag{M11.4.3.10}$$

The second particular solution, corresponding to $\lambda = -1$, is found in the same way:

$$y_1 = -2e^{-x}, \qquad y_2 = e^{-x}. \tag{M11.4.3.11}$$

The sum of the two particular solutions (M11.4.3.10) and (M11.4.3.11) multiplied by arbitrary constants, C_1 and C_2, gives the general solution to the original homogeneous system of linear ordinary differential equations:

$$y_1 = 2C_1e^{3x} - 2C_2e^{-x}, \qquad y_2 = C_1e^{3x} + C_2e^{-x}.$$

Example 2. Consider the system of ordinary differential equations

$$\begin{aligned} y_1' &= -y_2, \\ y_2' &= 2y_1 + 2y_2. \end{aligned} \tag{M11.4.3.12}$$

The characteristic equation

$$\begin{vmatrix} -\lambda & -1 \\ 2 & 2-\lambda \end{vmatrix} = \lambda^2 - 2\lambda + 2 = 0$$

has complex conjugate roots:

$$\lambda_1 = 1 + i, \qquad \lambda_2 = 1 - i.$$

The algebraic system (M11.4.3.6) for the complex coefficients A_1 and A_2 becomes

$$\begin{aligned} -\lambda A_1 - A_2 &= 0, \\ 2A_1 + (2-\lambda)A_2 &= 0. \end{aligned}$$

With $\lambda = 1 + i$, one nonzero solution is given by $A_1 = 1$ and $A_2 = -1 - i$. The corresponding complex solution to system (M11.4.3.12) has the form

$$y_1 = e^{(1+i)x}, \qquad y_2 = (-1-i)e^{(1+i)x}.$$

Separating the real and imaginary parts, taking into account the formulas

$$e^{(1+i)x} = e^x(\cos x + i\sin x) = e^x\cos x + ie^x\sin x,$$
$$(-1-i)e^{(1+i)x} = -(1+i)e^x(\cos x + i\sin x) = e^x(\sin x - \cos x) - ie^x(\sin x + \cos x),$$

and making linear combinations of them, one arrives at the general solution to the original system (M11.4.3.12):

$$y_1 = C_1e^x\cos x + C_2e^x\sin x,$$
$$y_2 = C_1e^x(\sin x - \cos x) - C_2e^x(\sin x + \cos x).$$

► **Nonhomogeneous systems of linear first-order equations.**

1°. In general, a nonhomogeneous linear system of first-order differential equations with constant coefficients has the form

$$\begin{aligned} y_1' &= a_{11}y_1 + a_{12}y_2 + \cdots + a_{1n}y_n + f_1(x),\\ y_2' &= a_{21}y_1 + a_{22}y_2 + \cdots + a_{2n}y_n + f_2(x),\\ &\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\\ y_n' &= a_{n1}y_1 + a_{n2}y_2 + \cdots + a_{nn}y_n + f_n(x). \end{aligned} \qquad \text{(M11.4.3.13)}$$

For brevity, the conventional vector notation will also be used:

$$\mathbf{y}' = \mathbf{A}\mathbf{y} + \mathbf{f}(x),$$

where $\mathbf{f}(x) = (f_1(x), f_2(x), \ldots, f_n(x))^{\mathrm{T}}$.

The general solution of this system is the sum of the general solution to the corresponding homogeneous system with $f_k(x) \equiv 0$ [see system (M11.4.3.1)] and any particular solution of the nonhomogeneous system (M11.4.3.13).

2°. Let $\mathbf{y}_k = (D_{k1}(x), D_{k1}(x), \ldots, D_{kn}(x))^{\mathrm{T}}$ be particular solutions to the homogeneous linear system of first-order constant-coefficient differential equations (M11.4.3.1) that satisfy the special initial conditions

$$y_k(0) = 1, \quad y_m(0) = 0 \quad \text{for} \quad m \neq k; \quad k,\, m = 1,\, \ldots,\, n.$$

Then the general solution to the nonhomogeneous system (M11.4.3.13) is expressed as

$$y_m(x) = \sum_{k=1}^{n} \int_0^x f_k(t)D_{km}(x-t)\,dt + \sum_{k=1}^{n} C_kD_{km}(x), \qquad m = 1, \ldots, n. \qquad \text{(M11.4.3.14)}$$

The solution of the Cauchy problem for the nonhomogeneous system (M11.4.3.13) with arbitrary initial conditions,

$$y_1(0) = y_1^\circ, \quad y_2(0) = y_2^\circ, \quad \ldots, \quad y_n(0) = y_n^\circ, \qquad \text{(M11.4.3.15)}$$

is determined by formulas (M11.4.3.14) with $C_k = y_k^\circ$, $k = 1, \ldots, n$.

M11.5. Nonlinear Equations of Arbitrary Order

M11.5.1. Structure of the General Solution. Cauchy Problem

► **Equations solved for the highest derivative. General solution.** An *nth-order differential equation solved for the highest derivative* has the form

$$y_x^{(n)} = f(x, y, y_x', \ldots, y_x^{(n-1)}). \qquad \text{(M11.5.1.1)}$$

The general solution of this equation depends on n arbitrary constants $C_1, \dots, C_n$. In some cases, the general solution can be written in explicit form as

$$y = \varphi(x, C_1, \dots, C_n). \qquad \text{(M11.5.1.2)}$$

► **Cauchy problem. The existence and uniqueness theorem.** The *Cauchy problem*: find a solution of equation (M11.5.1.1) with the *initial conditions*

$$y(x_0) = y_0, \quad y'_x(x_0) = y_0^{(1)}, \quad \dots, \quad y_x^{(n-1)}(x_0) = y_0^{(n-1)}. \qquad \text{(M11.5.1.3)}$$

(At a point x_0, the values of the unknown function $y(x)$ and all its derivatives of orders $\le n-1$ are prescribed.)

EXISTENCE AND UNIQUENESS THEOREM. *Suppose the function $f(x, y, z_1, \dots, z_{n-1})$ is continuous in all its arguments in a neighborhood of the point $(x_0, y_0, y_0^{(1)}, \dots, y_0^{(n-1)})$ and has bounded derivatives with respect to y, z_1, $\dots$, z_{n-1} in this neighborhood. Then a solution of equation (M11.5.1.1) satisfying the initial conditions (M11.5.1.3) exists and is unique.*

► **Reduction of an nth-order equation to a system of n first-order equations.** The differential equation (M11.5.1.1) is equivalent to the following system of n first-order equations:

$$y'_0 = y_1, \quad y'_1 = y_2, \quad \dots, \quad y'_{n-2} = y_{n-1}, \quad y'_{n-1} = f(x, y_0, y_1, \dots, y_{n-1}),$$

where the notation $y_0 \equiv y$ is adopted.

M11.5.2. Equations Admitting Reduction of Order

► **Equations not containing $y, y'_x, \dots, y_x^{(k)}$ explicitly.** An equation that does not explicitly contain the unknown function and its derivatives up to order k inclusive can generally be written as

$$F\big(x, y_x^{(k+1)}, \dots, y_x^{(n)}\big) = 0 \qquad (1 \le k+1 < n). \qquad \text{(M11.5.2.1)}$$

Such equations are invariant under arbitrary translations of the unknown function, $y \to y + \text{const}$ (the form of such equations is also preserved under the transformation $u(x) = y + a_k x^k + \dots + a_1 x + a_0$, where the a_m are arbitrary constants). The substitution $z(x) = y_x^{(k+1)}$ reduces (M11.5.2.1) to an equation whose order is by $k+1$ smaller than that of the original equation, $F\big(x, z, z'_x, \dots, z_x^{(n-k-1)}\big) = 0$.

► **Equations not containing x explicitly (autonomous equations).** In general, an equation that does not explicitly contain x has form

$$F\big(y, y'_x, \dots, y_x^{(n)}\big) = 0. \qquad \text{(M11.5.2.2)}$$

Such equations are invariant under arbitrary translations of the independent variable, $x \to x + \text{const}$. The substitution $y'_x = w(y)$ (where y plays the role of the independent variable) reduces by one the order of an autonomous equation. Higher derivatives can be expressed in terms of w and its derivatives with respect to the new independent variable, $y''_{xx} = ww'_y$, $y'''_{xxx} = w^2 w''_{yy} + w(w'_y)^2, \dots$

► **Some other equations admitting reduction of order.** Table M11.5 lists the above nonlinear equations as well as some other equations admitting order reduction. The second column gives simple transformations that allow checking whether the equation is one of this type.

TABLE M11.5
Some ordinary differential equations that admit order reduction by one.

Equation	Transformation preserving form of equation (a is an arbitrary constant)	Transformation reducing order of equation, $u=u(z)$
$F\bigl(x, y'_x, y''_{xx}, \dots, y_x^{(n)}\bigr)=0$	$y=\bar{y}+a$	$z=x,\ u=y'_x$
$F\bigl(y, y'_x, y''_{xx}, \dots, y_x^{(n)}\bigr)=0$	$x=\bar{x}+a$	$z=y,\ u=y'_x$
$F\bigl(\alpha x+\beta y+\gamma, y'_x, y''_{xx}, \dots, y_x^{(n)}\bigr)=0$	$x=\bar{x}+a\beta,\ y=\bar{y}-a\alpha$	$z=\alpha x+\beta y+\gamma,\ u=y'_x$
$F\bigl(x, y'_x/y, y''_{xx}/y, \dots, y_x^{(n)}/y\bigr)=0$	$y=a\bar{y}$	$z=x,\ u=y'_x/y$
$F\bigl(y, xy'_x, x^2y''_{xx}, \dots, x^ny_x^{(n)}\bigr)=0$	$x=a\bar{x}$	$z=y,\ u=xy'_x$
$F\bigl(y/x, y'_x, xy''_{xx}, \dots, x^{n-1}y_x^{(n)}\bigr)=0$	$x=a\bar{x},\ y=a\bar{y}$	$z=y/x,\ u=y'_x$
$F\bigl(e^{\lambda x}y, y'_x/y, y''_{xx}/y, \dots, y_x^{(n)}/y\bigr)=0$	$x=\bar{x}-\frac{1}{\lambda}\ln a,\ y=a\bar{y}$	$z=e^{\lambda x}y,\ u=y'_x/y$
$F\bigl(xe^{\lambda y}, xy'_x, x^2y''_{xx}, \dots, x^ny_x^{(n)}\bigr)=0$	$x=a\bar{x},\ y=\bar{y}-\frac{1}{\lambda}\ln a$	$z=xe^{\lambda y},\ u=xy'_x$
$F\bigl(x^ky, x^{k+1}y'_x, x^{k+2}y''_{xx}, \dots, x^{k+n}y_x^{(n)}\bigr)=0$	$x=a\bar{x},\ y=a^{-k}\bar{y}$	$z=x^ky,\ u=x^{k+1}y'_x$

Chapter M12

Partial Differential Equations

M12.1. First-Order Quasilinear Partial Differential Equations

M12.1.1. Characteristic System. General Solution

► **Equations with two independent variables. General solution. Examples.** A *first-order quasilinear partial differential equation with two independent variables* has the general form

$$f(x,y,w)\frac{\partial w}{\partial x}+g(x,y,w)\frac{\partial w}{\partial y}=h(x,y,w). \tag{M12.1.1.1}$$

Such equations are encountered in various applications (continuum mechanics, gas dynamics, hydrodynamics, heat and mass transfer, wave theory, acoustics, multiphase flows, chemical engineering, etc.).

If two independent integrals,

$$u_1(x,y,w)=C_1, \qquad u_2(x,y,w)=C_2, \tag{M12.1.1.2}$$

of the *characteristic system*

$$\frac{dx}{f(x,y,w)}=\frac{dy}{g(x,y,w)}=\frac{dw}{h(x,y,w)} \tag{M12.1.1.3}$$

are known, then the *general solution* of equation (M12.1.1.1) is given by

$$\Phi(u_1,u_2)=0, \tag{M12.1.1.4}$$

where $\Phi(u,v)$ is an arbitrary function of two variables. With equation (M12.1.1.4) solved for u_1 or u_2, we often specify the general solution in the form

$$u_k=\Psi(u_{3-k}),$$

where $k=1$ or 2 and $\Psi(u)$ is an arbitrary function of one variable.

Remark. In the special case $h(x,y,w)\equiv 0$, one of the integrals of the characteristic system is $w=C_1$. Another integral may be determined from the first equation in (M12.1.1.3).

Example. Consider the linear constant coefficient equation

$$\frac{\partial w}{\partial x}+a\frac{\partial w}{\partial y}=b.$$

The characteristic system for this equation is

$$\frac{dx}{1}=\frac{dy}{a}=\frac{dw}{b}.$$

It has two independent integrals:

$$y-ax=C_1, \quad w-bx=C_2.$$

Hence, the general solution of the original equation is given by $\Phi(y-ax,\ w-bx)=0$. On solving this equation for w, one obtains the general solution in explicit form

$$w=bx+\Psi(y-ax),$$

where $\Psi(u)$ is an arbitrary function.

► **Equations with n independent variables. General solution.** A *first-order quasilinear partial differential equation with n independent variables* has the general form

$$f_1(x_1,\dots,x_n,w)\frac{\partial w}{\partial x_1}+\dots+f_n(x_1,\dots,x_n,w)\frac{\partial w}{\partial x_n}=g(x_1,\dots,x_n,w). \qquad \text{(M12.1.1.5)}$$

Let n independent integrals,

$$u_1(x_1,\dots,x_n,w)=C_1,\quad \dots,\quad u_n(x_1,\dots,x_n,w)=C_n,$$

of the characteristic system

$$\frac{dx_1}{f_1(x_1,\dots,x_n,w)}=\dots=\frac{dx_n}{f_n(x_1,\dots,x_n,w)}=\frac{dw}{g(x_1,\dots,x_n,w)}$$

be known. Then the general solution of equation (M12.1.1.5) is given by

$$\Phi(u_1,\dots,u_n)=0,$$

where Φ is an arbitrary function of n variables.

M12.1.2. Cauchy Problem

► **Two formulations of the Cauchy problem.** Consider two formulations of the Cauchy problem.

1°. *Generalized Cauchy problem.* Find a solution $w=w(x,y)$ of equation (M12.1.1.1) satisfying the initial conditions

$$x=h_1(\xi),\quad y=h_2(\xi),\quad w=h_3(\xi), \qquad \text{(M12.1.2.1)}$$

where ξ is a parameter ($\alpha\le\xi\le\beta$) and the $h_k(\xi)$ are given functions.

Geometric interpretation: find an integral surface of equation (M12.1.1.1) passing through the line defined parametrically by equations (M12.1.2.1).

2°. *Classical Cauchy problem.* Find a solution $w=w(x,y)$ of equation (M12.1.1.1) satisfying the initial condition

$$w=\varphi(y)\quad\text{at}\quad x=0, \qquad \text{(M12.1.2.2)}$$

where $\varphi(y)$ is a given function.

It is convenient to represent the classical Cauchy problem as a generalized Cauchy problem by rewriting condition (M12.1.2.2) in the parametric form

$$x=0,\quad y=\xi,\quad w=\varphi(\xi). \qquad \text{(M12.1.2.3)}$$

► **Procedure of solving the Cauchy problem.** The procedure of solving the Cauchy problem (M12.1.1.1), (M12.1.2.1) involves several steps. First, two independent integrals (M12.1.1.2) of the characteristic system (M12.1.1.3) are determined. Then, to find the constants of integration C_1 and C_2, the initial data (M12.1.2.1) must be substituted into the integrals (M12.1.1.2) to obtain

$$u_1\bigl(h_1(\xi),h_2(\xi),h_3(\xi)\bigr)=C_1,\qquad u_2\bigl(h_1(\xi),h_2(\xi),h_3(\xi)\bigr)=C_2. \qquad \text{(M12.1.2.4)}$$

Eliminating C_1 and C_2 from (M12.1.1.2) and (M12.1.2.4) yields

$$\begin{aligned}u_1(x,y,w)&=u_1\bigl(h_1(\xi),h_2(\xi),h_3(\xi)\bigr),\\ u_2(x,y,w)&=u_2\bigl(h_1(\xi),h_2(\xi),h_3(\xi)\bigr).\end{aligned} \qquad \text{(M12.1.2.5)}$$

Formulas (M12.1.2.5) are a parametric form of the solution of the Cauchy problem (M12.1.1.1), (M12.1.2.1). In some cases, one may succeed in eliminating the parameter ξ from relations (M12.1.2.5), thus obtaining the solution in an explicit form.

Example 1. Consider the Cauchy problem for linear equation

$$\frac{\partial w}{\partial x}+a\frac{\partial w}{\partial y}=bw \tag{M12.1.2.6}$$

subjected to the initial condition (M12.1.2.2).

The corresponding characteristic system for equation (M12.1.2.6),

$$\frac{dx}{1}=\frac{dy}{a}=\frac{dw}{bw},$$

has two independent integrals

$$y-ax=C_1,\qquad we^{-bx}=C_2. \tag{M12.1.2.7}$$

Represent the initial condition (M12.1.2.2) in parametric form (M12.1.2.3) and then substitute the data (M12.1.2.3) into the integrals (M12.1.2.7). As a result, for the constants of integration we obtain $C_1=\xi$ and $C_2=\varphi(\xi)$. Substituting these expressions into (M12.1.2.7), we arrive at the solution of the Cauchy problem (M12.1.2.6), (M12.1.2.2) in parametric form:

$$y-ax=\xi,\qquad we^{-bx}=\varphi(\xi).$$

By eliminating the parameter ξ from these relations, we obtain the solution of the Cauchy problem (M12.1.2.6), (M12.1.2.2) in explicit form:

$$w=e^{bx}\varphi(y-ax).$$

Example 2. Consider the Cauchy problem for *Hopf's equation*

$$\frac{\partial w}{\partial x}+w\frac{\partial w}{\partial y}=0 \tag{M12.1.2.8}$$

subject to the initial condition (M12.1.2.2).

First, we rewrite the initial condition (M12.1.2.2) in the parametric form (M12.1.2.3). Solving the characteristic system

$$\frac{dx}{1}=\frac{dy}{w}=\frac{dw}{0}, \tag{M12.1.2.9}$$

we find two independent integrals,

$$w=C_1,\quad y-wx=C_2. \tag{M12.1.2.10}$$

Using the initial conditions (M12.1.2.3), we find that $C_1=\varphi(\xi)$ and $C_2=\xi$. Substituting these expressions into (M12.1.2.10) yields the solution of the Cauchy problem (M12.1.2.8), (M12.1.2.2) in the parametric form

$$w=\varphi(\xi), \tag{M12.1.2.11}$$

$$y=\xi+\varphi(\xi)x. \tag{M12.1.2.12}$$

The straight lines defined by equation (M12.1.2.12) are called *characteristics*. They have the slope $\varphi(\xi)$ and intersect the y-axis at the points ξ. On each characteristic, the function w has the same value equal to $\varphi(\xi)$ (generally, w takes different values on different characteristics).

For $\varphi'(\xi)>0$, different characteristics do not intersect and, hence, formulas (M12.1.2.11) and (M12.1.2.12) define a unique solution.

M12.2. Classification of Second-Order Linear Partial Differential Equations

M12.2.1. Equations with Two Independent Variables

► **Examples of equations encountered in applications.** There are three basic types of linear partial differential equations—*parabolic*, *hyperbolic*, and *elliptic*. The solutions of the equations pertaining to each of the types have their own characteristic qualitative differences.

The simplest example of a *parabolic equation* is the *heat equation*

$$\frac{\partial w}{\partial t}-\frac{\partial^2 w}{\partial x^2}=0, \tag{M12.2.1.1}$$

where the variables t and x play the role of time and the spatial coordinate, respectively. Note that equation (M12.2.1.1) contains only one highest derivative term. Frequently encountered particular solutions of equation (M12.2.1.1) can be found at the end of Subsection M12.4.1.

The simplest example of a *hyperbolic equation* is the *wave equation*

$$\frac{\partial^2 w}{\partial t^2} - \frac{\partial^2 w}{\partial x^2} = 0, \tag{M12.2.1.2}$$

where the variables t and x play the role of time and the spatial coordinate, respectively. Note that the highest derivative terms in equation (M12.2.1.2) differ in sign. The general solution of equation (M12.2.1.2) can be found at the end of Subsection M12.4.1.

The simplest example of an *elliptic equation* is the *Laplace equation*

$$\frac{\partial^2 w}{\partial x^2} + \frac{\partial^2 w}{\partial y^2} = 0, \tag{M12.2.1.3}$$

where x and y play the role of the spatial coordinates. Note that the highest derivative terms in equation (M12.2.1.3) have like signs. Frequently encountered particular solutions of equation (M12.2.1.3) can be found at the end of Subsection M12.4.1.

Any linear partial differential equation of the second order with two independent variables can be reduced, by appropriate manipulations, to a simpler equation that has one of the three highest derivative combinations specified above in examples (M12.2.1.1), (M12.2.1.2), and (M12.2.1.3).

► **Types of equations. Characteristic equations.** Consider a second-order partial differential equation with two independent variables that has the general form

$$a(x,y)\frac{\partial^2 w}{\partial x^2} + 2b(x,y)\frac{\partial^2 w}{\partial x \partial y} + c(x,y)\frac{\partial^2 w}{\partial y^2} = F\left(x, y, w, \frac{\partial w}{\partial x}, \frac{\partial w}{\partial y}\right), \tag{M12.2.1.4}$$

where a, b, c are some functions of x and y that have continuous derivatives up to the second order inclusive.*

Given a point (x, y), equation (M12.2.1.4) is said to be

$$\begin{array}{ll} \textit{parabolic} & \text{if } b^2 - ac = 0, \\ \textit{hyperbolic} & \text{if } b^2 - ac > 0, \\ \textit{elliptic} & \text{if } b^2 - ac < 0 \end{array}$$

at this point.

In order to reduce equation (M12.2.1.4) to a canonical form, one should first write out the characteristic equation

$$a\,(dy)^2 - 2b\,dx\,dy + c\,(dx)^2 = 0,$$

which splits into two equations

$$a\,dy - \left(b + \sqrt{b^2 - ac}\right)dx = 0 \tag{M12.2.1.5}$$

and

$$a\,dy - \left(b - \sqrt{b^2 - ac}\right)dx = 0, \tag{M12.2.1.6}$$

and then find their general integrals.

---

* The right-hand side of equation (M12.2.1.4) may be nonlinear. The classification and the procedure of reducing such equations to a canonical form are only determined by the left-hand side of the equation.

Remark. The characteristic equations (M12.2.1.5) and (M12.2.1.6) may be used if $a \not\equiv 0$. If $a \equiv 0$, the simpler equations

$$dx = 0,$$
$$2b\,dy - c\,dx = 0$$

should be used; the first equation has the obvious general solution $x = C$.

► **Canonical form of parabolic equations (case $b^2 - ac = 0$).** In this case, equations (M12.2.1.5) and (M12.2.1.6) coincide and have a common general integral,

$$\varphi(x,y) = C.$$

By passing from x, y to new independent variables ξ, η in accordance with the relations

$$\xi = \varphi(x,y), \qquad \eta = \eta(x,y),$$

where $\eta = \eta(x,y)$ is any twice differentiable function that satisfies the condition of nondegeneracy of the Jacobian $\frac{D(\xi,\eta)}{D(x,y)}$ in the given domain, we reduce equation (M12.2.1.4) to the canonical form

$$\frac{\partial^2 w}{\partial \eta^2} = F_1\left(\xi, \eta, w, \frac{\partial w}{\partial \xi}, \frac{\partial w}{\partial \eta}\right). \qquad \text{(M12.2.1.7)}$$

As η, one can take $\eta = x$ or $\eta = y$.

It is apparent that the transformed equation (M12.2.1.7) has only one highest-derivative term, just as the heat equation (M12.2.1.1).

Remark. In the degenerate case where the function F_1 does not depend on the partial derivative $\partial_\xi w$, equation (M12.2.1.7) is an ordinary differential equation for the variable η, in which ξ serves as a parameter.

► **Canonical forms of hyperbolic equations (case $b^2 - ac > 0$).** The general integrals

$$\varphi(x,y) = C_1, \qquad \psi(x,y) = C_2$$

of equations (M12.2.1.5) and (M12.2.1.6) are real and different. These integrals determine two different families of real characteristics.

By passing from x, y to new independent variables ξ, η in accordance with the relations

$$\xi = \varphi(x,y), \qquad \eta = \psi(x,y),$$

we reduce equation (M12.2.1.4) to

$$\frac{\partial^2 w}{\partial \xi \partial \eta} = F_2\left(\xi, \eta, w, \frac{\partial w}{\partial \xi}, \frac{\partial w}{\partial \eta}\right).$$

This is the so-called *first canonical form of a hyperbolic equation*.

The transformation

$$\xi = t + z, \qquad \eta = t - z$$

brings the above equation to another canonical form,

$$\frac{\partial^2 w}{\partial t^2} - \frac{\partial^2 w}{\partial z^2} = F_3\left(t, z, w, \frac{\partial w}{\partial t}, \frac{\partial w}{\partial z}\right),$$

where $F_3 = 4F_2$. This is the so-called *second canonical form of a hyperbolic equation*. Apart from notation, the left-hand side of the last equation coincides with that of the wave equation (M12.2.1.2).

In some cases, reduction of an equation to a canonical form allows finding its general solution.

► **Canonical form of elliptic equations (case $b^2 - ac < 0$).** In this case the general integrals of equations (M12.2.1.5) and (M12.2.1.6) are complex conjugate; these determine two families of complex characteristics.

Let the general integral of equation (M12.2.1.5) have the form

$$\varphi(x,y) + i\psi(x,y) = C, \qquad i^2 = -1,$$

where $\varphi(x,y)$ and $\psi(x,y)$ are real-valued functions.

By passing from x, y to new independent variables ξ, η in accordance with the relations

$$\xi = \varphi(x,y), \qquad \eta = \psi(x,y),$$

we reduce equation (M12.2.1.4) to the canonical form

$$\frac{\partial^2 w}{\partial \xi^2} + \frac{\partial^2 w}{\partial \eta^2} = F_4\left(\xi, \eta, w, \frac{\partial w}{\partial \xi}, \frac{\partial w}{\partial \eta}\right).$$

Apart from notation, the left-hand side of the last equation coincides with that of the Laplace equation (M12.2.1.3).

M12.2.2. Equations with Many Independent Variables

Let us consider a second-order partial differential equation with n independent variables $x_1, \dots, x_n$ that has the form

$$\sum_{i,j=1}^{n} a_{ij}(\mathbf{x}) \frac{\partial^2 w}{\partial x_i \partial x_j} = F\left(\mathbf{x}, w, \frac{\partial w}{\partial x_1}, \dots, \frac{\partial w}{\partial x_n}\right), \tag{M12.2.2.1}$$

where the a_{ij} are some functions that have continuous derivatives with respect to all variables to the second order inclusive, and $\mathbf{x} = \{x_1, \dots, x_n\}$. [The right-hand side of equation (M12.2.2.1) may be nonlinear. The left-hand side only is required for the classification of this equation.]

At a point $\mathbf{x} = \mathbf{x}_0$, the following quadratic form is assigned to equation (M12.2.2.1):

$$Q = \sum_{i,j=1}^{n} a_{ij}(\mathbf{x}_0) \xi_i \xi_j. \tag{M12.2.2.2}$$

By an appropriate linear nondegenerate transformation

$$\xi_i = \sum_{k=1}^{n} \beta_{ik} \eta_k \qquad (i = 1, \dots, n) \tag{M12.2.2.3}$$

the quadratic form (M12.2.2.2) can be reduced to the canonical form

$$Q = \sum_{i=1}^{n} c_i \eta_i^2, \tag{M12.2.2.4}$$

where the coefficients c_i assume the values 1, –1, and 0. The number of negative and zero coefficients in (M12.2.2.4) does not depend on the way in which the quadratic form is reduced to the canonical form.

TABLE M12.1
Classification of equations with many independent variables.

Type of equation (M12.2.2.1) at a point $\mathbf{x} = \mathbf{x}_0$	Coefficients of the canonical form (M12.2.2.4)
Parabolic (in the broad sense)	At least one coefficient of the c_i is zero
Hyperbolic (in the broad sense)	All c_i are nonzero and some c_i differ in sign
Elliptic	All c_i are nonzero and have like signs

Table M12.1 presents the basic criteria according to which the equations with many independent variables are classified.

Suppose all coefficients of the highest derivatives in (M12.2.2.1) are constant, $a_{ij} = \text{const}$. By introducing the new independent variables $y_1, \ldots, y_n$ in accordance with the formulas $y_i = \sum_{k=1}^{n} \beta_{ik} x_k$, where the β_{ik} are the coefficients of the linear transformation (M12.2.2.3), we reduce equation (M12.2.2.1) to the canonical form

$$\sum_{i=1}^{n} c_i \frac{\partial^2 w}{\partial y_i^2} = F_1\left(\mathbf{y}, w, \frac{\partial w}{\partial y_1}, \ldots, \frac{\partial w}{\partial y_n}\right). \tag{M12.2.2.5}$$

The coefficients c_i here are the same as in the quadratic form (M12.2.2.4), and $\mathbf{y} = \{y_1, \ldots, y_n\}$.

Specific equations of parabolic, hyperbolic, and elliptic types will be discussed further in Sections M12.3, M12.5, and M12.7–M12.9.

M12.3. Basic Problems for Linear Equations of Mathematical Physics

M12.3.1. Initial and Boundary Conditions. Cauchy Problem. Boundary Value Problems

Every equation of mathematical physics governs infinitely many qualitatively similar phenomena or processes. This follows from the fact that differential equations have infinitely many particular solutions. The specific solution that describes the physical phenomenon under study is isolated from the set of particular solutions of the given differential equation by means of initial and boundary conditions.

Throughout this section, we consider linear equations in the n-dimensional Euclidean space $\mathbb{R}^n$ or in an open domain $V \in \mathbb{R}^n$ (exclusive of the boundary) with a sufficiently smooth boundary $S = \partial V$.

► **Parabolic equations. Initial and boundary conditions.** In general, a linear second-order partial differential equation of the parabolic type with n independent variables can be written as

$$\frac{\partial w}{\partial t} - L_{\mathbf{x},t}[w] = \Phi(\mathbf{x}, t), \tag{M12.3.1.1}$$

where

$$L_{\mathbf{x},t}[w] \equiv \sum_{i,j=1}^{n} a_{ij}(\mathbf{x}, t) \frac{\partial^2 w}{\partial x_i \partial x_j} + \sum_{i=1}^{n} b_i(\mathbf{x}, t) \frac{\partial w}{\partial x_i} + c(\mathbf{x}, t) w, \tag{M12.3.1.2}$$

$$\mathbf{x} = \{x_1, \dots, x_n\}, \quad \sum_{i,j=1}^{n} a_{ij}(\mathbf{x}, t)\xi_i\xi_j \geq \sigma \sum_{i=1}^{n} \xi_i^2, \quad \sigma > 0.$$

Parabolic equations govern unsteady thermal, diffusion, and other phenomena dependent on time t.

Equation (M12.3.1.1) is called homogeneous if $\Phi(\mathbf{x}, t) \equiv 0$.

Cauchy problem ($t \geq 0$, $\mathbf{x} \in \mathbb{R}^n$). Find a function w that satisfies equation (M12.3.1.1) for $t > 0$ and the initial condition

$$w = f(\mathbf{x}) \quad \text{at} \quad t = 0. \tag{M12.3.1.3}$$

Example 1. The solution to the Cauchy problem for the one-dimensional heat equation (M12.2.1.1) with the initial condition (M12.3.1.3) is given by

$$w(x, t) = \frac{1}{2\sqrt{\pi t}} \int_{-\infty}^{\infty} f(\xi) \exp\left[-\frac{(x - \xi)^2}{4t}\right] d\xi.$$

The derivation of this formula is shown in the example of Subsection M12.6.2.

*Boundary value problem** ($t \geq 0$, $\mathbf{x} \in V$). Find a function w that satisfies equation (M12.3.1.1) for $t > 0$, the initial condition (M12.3.1.3), and the boundary condition

$$\Gamma_{\mathbf{x},t}[w] = g(\mathbf{x}, t) \quad \text{at} \quad \mathbf{x} \in S \qquad (t > 0). \tag{M12.3.1.4}$$

In general, $\Gamma_{\mathbf{x},t}$ is a first-order linear differential operator in the space variables $\mathbf{x}$ with coefficients dependent on $\mathbf{x}$ and t. The basic types of boundary conditions are described in Subsection M12.3.2.

The initial condition (M12.3.1.3) is called homogeneous if $f(\mathbf{x}) \equiv 0$. The boundary condition (M12.3.1.4) is called homogeneous if $g(\mathbf{x}, t) \equiv 0$.

► **Hyperbolic equations. Initial and boundary conditions.** Consider a second-order linear partial differential equation of the hyperbolic type with n independent variables of the general form

$$\frac{\partial^2 w}{\partial t^2} + \varphi(\mathbf{x}, t)\frac{\partial w}{\partial t} - L_{\mathbf{x},t}[w] = \Phi(\mathbf{x}, t), \tag{M12.3.1.5}$$

where the linear differential operator $L_{\mathbf{x},t}$ is defined by (M12.3.1.2). Hyperbolic equations govern unsteady wave processes, which depend on time t.

Equation (M12.3.1.5) is said to be homogeneous if $\Phi(\mathbf{x}, t) \equiv 0$.

Cauchy problem ($t \geq 0$, $\mathbf{x} \in \mathbb{R}^n$). Find a function w that satisfies equation (M12.3.1.5) for $t > 0$ and the initial conditions

$$\begin{aligned} w &= f_0(\mathbf{x}) \quad \text{at} \quad t = 0, \\ \partial_t w &= f_1(\mathbf{x}) \quad \text{at} \quad t = 0. \end{aligned} \tag{M12.3.1.6}$$

Example 2. The solution to the Cauchy problem for the one-dimensional wave equation (M12.2.1.2) with the initial conditions (M12.3.1.6) is given by *d'Alembert's formula*:

$$w(x, t) = \frac{1}{2}[f_0(x + t) + f_0(x - t)] + \frac{1}{2}\int_{x-t}^{x+t} f_1(\xi)\, d\xi.$$

Boundary value problem ($t \geq 0$, $\mathbf{x} \in V$). Find a function w that satisfies equation (M12.3.1.5) for $t > 0$, the initial conditions (M12.3.1.6), and boundary condition (M12.3.1.4).

The initial conditions (M12.3.1.6) are called homogeneous if $f_0(\mathbf{x}) \equiv 0$ and $f_1(\mathbf{x}) \equiv 0$.

Goursat problem. On the characteristics of a hyperbolic equation with two independent variables, the values of the unknown function w are prescribed; for details, see Subsection M12.8.3.

---

* *Boundary value problems* for parabolic and hyperbolic equations are sometimes called *mixed* or *initial-boundary value problems*.

► **Elliptic equations. Boundary conditions.** In general, a second-order linear partial differential equation of elliptic type with n independent variables can be written as

$$-L_{\mathbf{x}}[w] = \Phi(\mathbf{x}), \qquad \text{(M12.3.1.7)}$$

where

$$L_{\mathbf{x}}[w] \equiv \sum_{i,j=1}^{n} a_{ij}(\mathbf{x})\frac{\partial^2 w}{\partial x_i \partial x_j} + \sum_{i=1}^{n} b_i(\mathbf{x})\frac{\partial w}{\partial x_i} + c(\mathbf{x})w, \qquad \text{(M12.3.1.8)}$$

$$\sum_{i,j=1}^{n} a_{ij}(\mathbf{x})\xi_i\xi_j \ge \sigma \sum_{i=1}^{n} \xi_i^2, \quad \sigma > 0.$$

Elliptic equations govern steady-state thermal, diffusion, and other phenomena independent of time t.

Equation (M12.3.1.7) is said to be homogeneous if $\Phi(\mathbf{x}) \equiv 0$.

Boundary value problem. Find a function w that satisfies equation (M12.3.1.7) and the boundary condition

$$\Gamma_{\mathbf{x}}[w] = g(\mathbf{x}) \quad \text{at} \quad \mathbf{x} \in S. \qquad \text{(M12.3.1.9)}$$

In general, $\Gamma_{\mathbf{x}}$ is a first-order linear differential operator in the space variables $\mathbf{x}$. The basic types of boundary conditions are described below in Subsection M12.3.2.

The boundary condition (M12.3.1.9) is called homogeneous if $g(\mathbf{x}) \equiv 0$. The boundary value problem (M12.3.1.7)–(M12.3.1.9) is said to be homogeneous if $\Phi \equiv 0$ and $g \equiv 0$.

M12.3.2. First, Second, Third, and Mixed Boundary Value Problems

For any (parabolic, hyperbolic, and elliptic) second-order partial differential equations, it is conventional to distinguish four basic types of boundary value problems, depending on the form of the boundary conditions (M12.3.1.4) [see also the analogous condition (M12.3.1.9)]. For simplicity, here we confine ourselves to the case where the coefficients a_{ij} of equations (M12.3.1.1) and (M12.3.1.5), with the operator defined by (M12.3.1.2), have the special form

$$a_{ij}(\mathbf{x},t) = a(\mathbf{x},t)\delta_{ij}, \quad \delta_{ij} = \begin{cases} 1 & \text{if } i = j, \\ 0 & \text{if } i \ne j. \end{cases}$$

This situation is rather frequent in applications; such coefficients are used to describe various phenomena (processes) in isotropic media.

► **First boundary value problem.** The function $w(\mathbf{x},t)$ takes prescribed values at the boundary S of the domain:

$$w(\mathbf{x},t) = g_1(\mathbf{x},t) \quad \text{for} \quad \mathbf{x} \in S. \qquad \text{(M12.3.2.1)}$$

► **Second boundary value problem.** The derivative along the (outward) normal is prescribed at the boundary S of the domain:

$$\frac{\partial w}{\partial N} = g_2(\mathbf{x},t) \quad \text{for} \quad \mathbf{x} \in S. \qquad \text{(M12.3.2.2)}$$

In heat transfer problems, where w is temperature, the left-hand side of the boundary condition (M12.3.2.2) is proportional to the heat flux per unit area of the surface S.

TABLE M12.2
Boundary conditions for various boundary value problems specified by parabolic and hyperbolic equations in two independent variables ($x_1 \le x \le x_2$).

Type of problem	Boundary condition at $x = x_1$	Boundary condition at $x = x_2$
First boundary value problem	$w = g_1(t)$	$w = g_2(t)$
Second boundary value problem	$\partial_x w = g_1(t)$	$\partial_x w = g_2(t)$
Third boundary value problem	$\partial_x w + \beta_1 w = g_1(t)$ $(\beta_1 < 0)$	$\partial_x w + \beta_2 w = g_2(t)$ $(\beta_2 > 0)$
Mixed boundary value problem	$w = g_1(t)$	$\partial_x w = g_2(t)$
Mixed boundary value problem	$\partial_x w = g_1(t)$	$w = g_2(t)$

► **Third boundary value problem.** A linear relationship between the unknown function and its normal derivative is prescribed at the boundary S of the domain:

$$\frac{\partial w}{\partial N} + k(\mathbf{x}, t)w = g_3(\mathbf{x}, t) \quad \text{for} \quad \mathbf{x} \in S. \qquad \text{(M12.3.2.3)}$$

It is usually assumed that $k(\mathbf{x}, t) = \text{const}$. In mass transfer problems, where w is concentration, the boundary condition (M12.3.2.3) with $g_3 \equiv 0$ describes a surface chemical reaction of the first order.

► **Mixed boundary value problems.** Conditions of various types, listed above, are set at different portions of the boundary S.

If $g_1 \equiv 0$, $g_2 \equiv 0$, or $g_3 \equiv 0$, the respective boundary conditions (M12.3.2.1), (M12.3.2.2), and (M12.3.2.3) are said to be homogeneous.

Boundary conditions for various boundary value problems for parabolic and hyperbolic equations in two independent variables x and t are displayed in Table M12.2. The equation coefficients are assumed to be continuous, with the coefficients of the highest derivatives being nonzero in the range $x_1 \le x \le x_2$ considered.

Remark 1. For elliptic equations, the coefficients a_{ij} as well as the right-hand sides of the boundary conditions (M12.3.2.1)–(M12.3.2.3) are independent of time t.

Remark 2. For elliptic equations, the first boundary value problem is often called the *Dirichlet problem*, and the second boundary value problem is called the *Neumann problem*.

M12.4. Properties and Exact Solutions of Linear Equations

M12.4.1. Homogeneous Linear Equations and Their Particular Solutions

► **Preliminary remarks.** For brevity, in this paragraph a homogeneous linear partial differential equation will be written as

$$\mathcal{L}[w] = 0. \qquad \text{(M12.4.1.1)}$$

For second-order linear parabolic and hyperbolic equations, the linear differential operator $\mathcal{L}[w]$ is defined by the left-hand side of equations (M12.3.1.1) and (M12.3.1.5), respectively. It is assumed that equation (M12.4.1.1) is an arbitrary homogeneous linear partial differential equation of any order in the variables t, x_1, …, x_n with sufficiently smooth coefficients.

A linear differential operator $\mathcal{L}$ possesses the properties

$$\begin{aligned}&\mathcal{L}[w_1+w_2]=\mathcal{L}[w_1]+\mathcal{L}[w_2],\\&\mathcal{L}[Aw]=A\mathcal{L}[w],\qquad A=\text{const}.\end{aligned}$$

An arbitrary homogeneous linear equation (M12.4.1.1) has a trivial solution, $w\equiv 0$.

A function w is called a *classical solution* of equation (M12.4.1.1) if w, when substituted into (M12.4.1.1), turns the equation into an identity and if all partial derivatives of w that occur in (M12.4.1.1) are continuous; the notion of a classical solution is directly linked to the range of the independent variables. In what follows, we usually write “solution” instead of “classical solution” for brevity.

► **Use of particular solutions for the construction of other solutions.** Below are some properties of particular solutions of homogeneous linear equations.

1°. Let $w_1=w_1(\mathbf{x},t)$, $w_2=w_2(\mathbf{x},t)$, …, $w_k=w_k(\mathbf{x},t)$ be any particular solutions of the homogeneous equation (M12.4.1.1). Then the linear combination

$$w=A_1w_1+A_2w_2+\cdots+A_kw_k \qquad \text{(M12.4.1.2)}$$

with arbitrary constants A_1, A_2, …, A_k is also a solution of equation (M12.4.1.1); in physics, this property is known as the *principle of linear superposition*.

Suppose $\{w_k\}$ is an infinite sequence of solutions of equation (M12.4.1.1). Then the series $\sum\limits_{k=1}^{\infty} w_k$, irrespective of its convergence, is called a *formal solution* of (M12.4.1.1). If the solutions w_k are classical, the series is uniformly convergent, and the sum of the series has all the necessary partial derivatives, then the sum of the series is a classical solution of equation (M12.4.1.1).

2°. Let the coefficients of the linear differential operator $\mathcal{L}$ be independent of time t. If equation (M12.4.1.1) has a particular solution $\widetilde{w}=\widetilde{w}(\mathbf{x},t)$, then the partial derivatives of $\widetilde{w}$ with respect to time,*

$$\frac{\partial\widetilde{w}}{\partial t},\quad \frac{\partial^2\widetilde{w}}{\partial t^2},\quad \dots,\quad \frac{\partial^k\widetilde{w}}{\partial t^k},\quad \dots,$$

are also solutions of equation (M12.4.1.1).

3°. Let the coefficients of the linear differential operator $\mathcal{L}$ be independent of the space variables $x_1,\dots,x_n$. If equation (M12.4.1.1) has a particular solution $\widetilde{w}=\widetilde{w}(\mathbf{x},t)$, then the partial derivatives of $\widetilde{w}$ with respect to the space coordinates

$$\frac{\partial\widetilde{w}}{\partial x_1},\quad \frac{\partial\widetilde{w}}{\partial x_2},\quad \frac{\partial\widetilde{w}}{\partial x_3},\quad \dots,\quad \frac{\partial^2\widetilde{w}}{\partial x_1^2},\quad \frac{\partial^2\widetilde{w}}{\partial x_1\partial x_2},\quad \dots,\quad \frac{\partial^{k+m}\widetilde{w}}{\partial x_2^k\partial x_3^m},\quad \dots$$

are also solutions of equation (M12.4.1.1).

If the coefficients of $\mathcal{L}$ are independent of only one space coordinate, say x_1, and equation (M12.4.1.1) has a particular solution $\widetilde{w}=\widetilde{w}(\mathbf{x},t)$, then the partial derivatives

$$\frac{\partial\widetilde{w}}{\partial x_1},\quad \frac{\partial^2\widetilde{w}}{\partial x_1^2},\quad \dots,\quad \frac{\partial^k\widetilde{w}}{\partial x_1^k},\quad \dots$$

are also solutions of equation (M12.4.1.1).

---

* Here and in what follows, it is assumed that the particular solution $\widetilde{w}$ is differentiable sufficiently many times with respect to t and $x_1,\dots,x_n$ (or the parameters).

4°. Let the coefficients of the linear differential operator $\mathcal{L}$ be constant and let equation (M12.4.1.1) have a particular solution $\widetilde{w} = \widetilde{w}(\mathbf{x}, t)$. Then any partial derivatives of $\widetilde{w}$ with respect to time and the space coordinates (including mixed derivatives)

$$\frac{\partial \widetilde{w}}{\partial t}, \quad \frac{\partial \widetilde{w}}{\partial x_1}, \quad \dots, \quad \frac{\partial^2 \widetilde{w}}{\partial x_2^2}, \quad \frac{\partial^2 \widetilde{w}}{\partial t \partial x_1}, \quad \dots, \quad \frac{\partial^k \widetilde{w}}{\partial x_3^k}, \quad \dots$$

are solutions of equation (M12.4.1.1).

5°. Suppose equation (M12.4.1.1) has a particular solution dependent on a parameter μ, $\widetilde{w} = \widetilde{w}(\mathbf{x}, t; \mu)$, and the coefficients of the linear differential operator $\mathcal{L}$ are independent of μ (but can depend on time and the space coordinates). Then, by differentiating $\widetilde{w}$ with respect to μ, one obtains other solutions of equation (M12.4.1.1),

$$\frac{\partial \widetilde{w}}{\partial \mu}, \quad \frac{\partial^2 \widetilde{w}}{\partial \mu^2}, \quad \dots, \quad \frac{\partial^k \widetilde{w}}{\partial \mu^k}, \quad \dots$$

Example 1. A linear *heat equation with a source* of the form

$$\frac{\partial w}{\partial t} = a\frac{\partial^2 w}{\partial x^2} + bw$$

has a particular solution

$$w(x, t) = \exp[\mu x + (a\mu^2 + b)t],$$

where μ is an arbitrary constant. Differentiating this solution with respect to μ yields another solution

$$w(x, t) = (x + 2a\mu t)\exp[\mu x + (a\mu^2 + b)t].$$

Let some constants $\mu_1, \dots, \mu_k$ belong to the range of the parameter μ. Then the sum

$$w = A_1\widetilde{w}(\mathbf{x}, t; \mu_1) + \dots + A_k\widetilde{w}(\mathbf{x}, t; \mu_k), \qquad \text{(M12.4.1.3)}$$

where $A_1, \dots, A_k$ are arbitrary constants, is also a solution of the homogeneous linear equation (M12.4.1.1). The number of terms in the sum (M12.4.1.3) can be both finite and infinite.

6°. Another effective way of constructing solutions involves the following considerations. The particular solution $\widetilde{w}(\mathbf{x}, t; \mu)$, which depends on the parameter μ (as before, it is assumed that the coefficients of the linear differential operator $\mathcal{L}$ are independent of μ), is first multiplied by an arbitrary function $\varphi(\mu)$. Then the resulting expression is integrated with respect to μ over some interval $[\alpha, \beta]$. Thus, one obtains a new function,

$$\int_\alpha^\beta \widetilde{w}(\mathbf{x}, t; \mu)\varphi(\mu)\, d\mu,$$

which is also a solution of the original homogeneous linear equation.

The properties listed in Items 1°–6° enable one to use known particular solutions to construct other particular solutions of homogeneous linear equations of mathematical physics.

► **Multiplicative separable solutions.** Many homogeneous linear partial differential equations have solutions that can be represented as the product of functions depending on different arguments. Such solutions are referred to as *multiplicative separable solutions*; very commonly these solutions are briefly, but less accurately, called just *separable solutions*.

TABLE M12.3
Homogeneous linear partial differential equations that admit multiplicative separable solutions.

No.	Form of equation (M12.4.1.1)	Form of particular solutions
1	Equation coefficients are constant	$w(\mathbf{x},t)=A\exp(\lambda t+\beta_1x_1+\cdots+\beta_nx_n)$, $\lambda,\beta_1,\dots,\beta_n$ are related by an algebraic equation
2	Equation coefficients are independent of time t	$w(\mathbf{x},t)=e^{\lambda t}\psi(\mathbf{x})$, λ is an arbitrary constant, $\mathbf{x}=\{x_1,\dots,x_n\}$
3	Equation coefficients are independent of the coordinates $x_1,\dots,x_n$	$w(\mathbf{x},t)=\exp(\beta_1x_1+\cdots+\beta_nx_n)\psi(t)$, $\beta_1,\dots,\beta_n$ are arbitrary constants
4	Equation coefficients are independent of the coordinates $x_1,\dots,x_k$	$w(\mathbf{x},t)=\exp(\beta_1x_1+\cdots+\beta_kx_k)\psi(t,x_{k+1},\dots,x_n)$, $\beta_1,\dots,\beta_k$ are arbitrary constants
5	$L_t[w]+L_{\mathbf{x}}[w]=0$, operator L_t depends on only t, operator $L_{\mathbf{x}}$ depends on only $\mathbf{x}$	$w(\mathbf{x},t)=\varphi(t)\psi(\mathbf{x})$, $\varphi(t)$ satisfies the equation $L_t[\varphi]+\lambda\varphi=0$, $\psi(\mathbf{x})$ satisfies the equation $L_{\mathbf{x}}[\psi]-\lambda\psi=0$
6	$L_t[w]+L_1[w]+\cdots+L_n[w]=0$, operator L_t depends on only t, operator L_k depends on only x_k	$w(\mathbf{x},t)=\varphi(t)\psi_1(x_1)\dots\psi_n(x_n)$, $\varphi(t)$ satisfies the equation $L_t[\varphi]+\lambda\varphi=0$, $\psi_k(x_k)$ satisfies the equation $L_k[\psi_k]+\beta_k\psi_k=0$, $\lambda+\beta_1+\cdots+\beta_n=0$
7	$f_0(x_1)L_t[w]+\sum\limits_{k=1}^{n}f_k(x_1)L_k[w]=0$, operator L_t depends on only t, operator L_k depends on only x_k	$w(\mathbf{x},t)=\varphi(t)\psi_1(x_1)\dots\psi_n(x_n)$, $L_t[\varphi]+\lambda\varphi=0$, $L_k[\psi_k]+\beta_k\psi_k=0,\quad k=2,\dots,n$, $f_1(x_1)L_1[\psi_1]-\Big[\lambda f_0(x_1)+\sum\limits_{k=2}^{n}\beta_kf_k(x_1)\Big]\psi_1=0$

Table M12.3 presents the most commonly encountered types of homogeneous linear differential equations with many independent variables that admit exact separable solutions. Linear combinations of particular solutions that correspond to different values of the separation parameters, λ, β_1, …, β_n, are also solutions of the equations in question. For brevity, the word "operator" is used below to denote "linear differential operator."

For a constant coefficient equation (see the first row in Table M12.3), the separation parameters must satisfy the algebraic equation

$$D(\lambda,\,\beta_1,\,\dots,\beta_n)=0, \qquad \text{(M12.4.1.4)}$$

which results from substituting the solution into equation (M12.4.1.1). In physical applications, equation (M12.4.1.4) is usually referred to as a *dispersion equation*. Any n of the $n+1$ separation parameters in (M12.4.1.4) can be treated as arbitrary.

Example 2. Consider the *telegraph equation*

$$\frac{\partial^2w}{\partial t^2}+k\frac{\partial w}{\partial t}=a^2\frac{\partial^2w}{\partial x^2}+b\frac{\partial w}{\partial x}+cw.$$

A particular solution is sought in the form

$$w=A\exp(\beta x+\lambda t).$$

This results in the dispersion equation $\lambda^2+k\lambda=a^2\beta^2+b\beta+c$, where one of the two parameters β or λ can be treated as arbitrary.

Remark 1. For stationary equations that do not depend on t, one should set $\lambda=0$, $L_t[w]\equiv0$, and $\varphi(t)\equiv1$ in rows 1, 6, and 7 of Table M12.3.

Remark 2. Multiplicative separable solutions play an important role in the theory of linear partial differential equations; they are used for finding solutions to stationary and nonstationary boundary value problems; see Sections M12.5 and M12.7–M12.9.

► Solutions of some linear equations encountered in applications.

1°. Some particular solutions of the heat equation

$$\frac{\partial w}{\partial t} = a\frac{\partial^2 w}{\partial x^2}$$

are listed below:

$$\begin{aligned}
w(x) &= Ax + B,\\
w(x,t) &= A(x^2 + 2at) + B,\\
w(x,t) &= A(x^3 + 6atx) + B,\\
w(x,t) &= A(x^4 + 12atx^2 + 12a^2t^2) + B,\\
w(x,t) &= x^{2n} + \sum_{k=1}^{n} \frac{(2n)(2n-1)\dots(2n-2k+1)}{k!}(at)^k x^{2n-2k},\\
w(x,t) &= x^{2n+1} + \sum_{k=1}^{n} \frac{(2n+1)(2n)\dots(2n-2k+2)}{k!}(at)^k x^{2n-2k+1},\\
w(x,t) &= A\exp(a\mu^2 t \pm \mu x) + B,\\
w(x,t) &= A\frac{1}{\sqrt{t}}\exp\left(-\frac{x^2}{4at}\right) + B,\\
w(x,t) &= A\frac{x}{t^{3/2}}\exp\left(-\frac{x^2}{4at}\right) + B,\\
w(x,t) &= A\exp(-a\mu^2 t)\cos(\mu x + B) + C,\\
w(x,t) &= A\exp(-\mu x)\cos(\mu x - 2a\mu^2 t + B) + C,\\
w(x,t) &= A\,\mathrm{erf}\left(\frac{x}{2\sqrt{at}}\right) + B,
\end{aligned}$$

where A, B, C, and μ are arbitrary constants, n is a positive integer, and $\mathrm{erf}\, z \equiv \frac{2}{\sqrt{\pi}}\int_0^z \exp(-\xi^2)\,d\xi$ is the error function (probability integral).

2°. The general solution of the wave equation

$$\frac{\partial^2 w}{\partial t^2} = a^2\frac{\partial^2 w}{\partial x^2}$$

is given by

$$w(x,t) = \varphi(x + at) + \psi(x - at),$$

where $\varphi(z_1)$ and $\psi(z_2)$ are arbitrary functions.

3°. Particular solutions of Laplace equation (M12.2.1.3) in the Cartesian coordinate system:

$$\begin{aligned}
w(x,y) &= Ax + By + C,\\
w(x,y) &= A(x^2 - y^2) + Bxy,
\end{aligned}$$

$$
\begin{aligned}
w(x,y) &= A(x^3-3xy^2)+B(3x^2y-y^3),\\
w(x,y) &= \frac{Ax+By}{x^2+y^2}+C,\\
w(x,y) &= \exp(\pm\mu x)(A\cos\mu y+B\sin\mu y),\\
w(x,y) &= (A\cos\mu x+B\sin\mu x)\exp(\pm\mu y),\\
w(x,y) &= (A\sinh\mu x+B\cosh\mu x)(C\cos\mu y+D\sin\mu y),\\
w(x,y) &= (A\cos\mu x+B\sin\mu x)(C\sinh\mu y+D\cosh\mu y),
\end{aligned}
$$

where A, B, C, D, and μ are arbitrary constants.

Particular solutions of Laplace equation (M12.2.1.3) in the polar coordinate system:

$$
\begin{aligned}
w(r) &= A\ln r+B,\\
w(r,\varphi) &= \left(Ar^m+\frac{B}{r^m}\right)(C\cos m\varphi+D\sin m\varphi),
\end{aligned}
$$

where A, B, C, and D are arbitrary constants, and $m = 1, 2, \ldots$

M12.4.2. Nonhomogeneous Linear Equations and Their Particular Solutions

► **Simplest properties of nonhomogeneous linear equations.** For brevity, we write a nonhomogeneous linear partial differential equation in the form

$$\mathcal{L}[w] = \Phi(\mathbf{x},t), \qquad \text{(M12.4.2.1)}$$

where the linear differential operator $\mathcal{L}$ is defined above (see the beginning of Subsection M12.4.1).

Below are the simplest properties of particular solutions of the nonhomogeneous equation (M12.4.2.1).

1°. If $\widetilde{w}_\Phi(\mathbf{x},t)$ is a particular solution of the nonhomogeneous equation (M12.4.2.1) and $\widetilde{w}_0(\mathbf{x},t)$ is a particular solution of the corresponding homogeneous equation (M12.4.1.1), then the sum

$$A\widetilde{w}_0(\mathbf{x},t)+\widetilde{w}_\Phi(\mathbf{x},t),$$

with arbitrary constant A, is also a solution of the nonhomogeneous equation (M12.4.2.1). The following, more general statement holds: The general solution of the nonhomogeneous equation (M12.4.2.1) is the sum of the general solution of the corresponding homogeneous equation (M12.4.1.1) and any particular solution of the nonhomogeneous equation (M12.4.2.1).

2°. Suppose w_1 and w_2 are solutions of nonhomogeneous linear equations with the same left-hand side and different right-hand sides, i.e.,

$$\mathcal{L}[w_1] = \Phi_1(\mathbf{x},t), \qquad \mathcal{L}[w_2] = \Phi_2(\mathbf{x},t).$$

Then the function $w = w_1 + w_2$ is a solution of the equation

$$\mathcal{L}[w] = \Phi_1(\mathbf{x},t)+\Phi_2(\mathbf{x},t).$$

► **Fundamental and particular solutions of stationary equations.** Consider the second-order linear stationary (time-independent) nonhomogeneous equation

$$L_{\mathbf{x}}[w] = -\Phi(\mathbf{x}). \tag{M12.4.2.2}$$

Here, $L_{\mathbf{x}}$ is a linear differential operator of the second (or any) order of general form whose coefficients are dependent on $\mathbf{x}$, where $\mathbf{x} \in \mathbb{R}^n$.

A function $\mathscr{E} = \mathscr{E}(\mathbf{x}, \mathbf{y})$ that satisfies the equation with a special right-hand side

$$L_{\mathbf{x}}[\mathscr{E}] = -\delta(\mathbf{x} - \mathbf{y}) \tag{M12.4.2.3}$$

is called a *fundamental solution* corresponding to the operator $L_{\mathbf{x}}$. In (M12.4.2.3), $\delta(\mathbf{x})$ is an n-dimensional Dirac delta function and the vector quantity $\mathbf{y} = \{y_1, \dots, y_n\}$ appears in equation (M12.4.2.3) as an n-dimensional free parameter. It is assumed that $\mathbf{y} \in \mathbb{R}^n$.

The n-dimensional Dirac delta function possesses the following basic properties:

1. $\delta(\mathbf{x}) = \delta(x_1)\delta(x_2)\dots\delta(x_n)$,
2. $\displaystyle\int_{\mathbb{R}^n} \Phi(\mathbf{y})\delta(\mathbf{x} - \mathbf{y})\,d\mathbf{y} = \Phi(\mathbf{x})$,

where $\delta(x_k)$ is the one-dimensional Dirac delta function, $\Phi(\mathbf{x})$ is an arbitrary continuous function, and $d\mathbf{y} = dy_1 \dots dy_n$.

For constant coefficient equations, a fundamental solution always exists.

The fundamental solution $\mathscr{E} = \mathscr{E}(\mathbf{x}, \mathbf{y})$ can be used to construct a particular solution of the linear stationary nonhomogeneous equation (M12.4.2.2) for arbitrary continuous $\Phi(\mathbf{x})$; this particular solution is expressed as follows:

$$w(\mathbf{x}) = \int_{\mathbb{R}^n} \Phi(\mathbf{y})\mathscr{E}(\mathbf{x}, \mathbf{y})\,d\mathbf{y}. \tag{M12.4.2.4}$$

Remark 1. The fundamental solution $\mathscr{E}$ is not unique; it is defined up to an additive term $w_0 = w_0(\mathbf{x})$, which is an arbitrary solution of the homogeneous equation $L_{\mathbf{x}}[w_0] = 0$.

Remark 2. For constant coefficient differential equations, the fundamental solution possesses the property $\mathscr{E}(\mathbf{x}, \mathbf{y}) = \mathscr{E}(\mathbf{x} - \mathbf{y})$.

Remark 3. The right-hand sides of equations (M12.4.2.2) and (M12.4.2.3) are often prefixed with the plus sign. In this case, formula (M12.4.2.4) remains valid.

Example. For the two- and three-dimensional *Poisson equations*, the fundamental solutions have the forms

Equations		*Fundamental solutions*
$\dfrac{\partial^2 w}{\partial x_1^2} + \dfrac{\partial^2 w}{\partial x_2^2} = -\Phi(x_1, x_2)$	$\Longrightarrow$	$\mathscr{E}(x_1, x_2, y_1, y_2) = \dfrac{1}{2\pi} \ln \dfrac{1}{\rho}$,
$\dfrac{\partial^2 w}{\partial x_1^2} + \dfrac{\partial^2 w}{\partial x_2^2} + \dfrac{\partial^2 w}{\partial x_3^2} = -\Phi(x_1, x_2, x_3)$	$\Longrightarrow$	$\mathscr{E}(x_1, x_2, x_3, y_1, y_2, y_3) = \dfrac{1}{4\pi r}$,

where $\rho = \sqrt{(x_1 - y_1)^2 + (x_2 - y_2)^2}$ and $r = \sqrt{(x_1 - y_1)^2 + (x_2 - y_2)^2 + (x_3 - y_3)^2}$.

M12.5. Method of Separation of Variables (Fourier Method)

M12.5.1. Solution of Problems for Parabolic Equations

► **Mathematical statement of the problem.** Consider boundary value problems for a linear homogeneous parabolic equation of the form

$$\frac{\partial w}{\partial t} = a(x)\frac{\partial^2 w}{\partial x^2} + b(x)\frac{\partial w}{\partial x} + \big[c(x) + \gamma(t)\big]w \tag{M12.5.1.1}$$

with homogeneous linear boundary conditions,

$$\begin{aligned} s_1\partial_x w + k_1 w = 0 \quad &\text{at} \quad x = x_1,\\ s_2\partial_x w + k_2 w = 0 \quad &\text{at} \quad x = x_2, \end{aligned} \qquad \text{(M12.5.1.2)}$$

and an arbitrary initial condition,

$$w = f_0(x) \quad \text{at} \quad t = 0. \qquad \text{(M12.5.1.3)}$$

We assume that the coefficients of equation (M12.5.1.1) and boundary conditions (M12.5.1.2) meet the following requirements:

$a(x)$, $b(x)$, $c(x)$, and $\gamma(t)$ are continuous functions; $a(x) > 0$, $|s_1| + |k_1| > 0$, $|s_2| + |k_2| > 0$.

Remark. In various applications, equations of the form (M12.5.1.1) may arise with the coefficient $b(x)$ going to infinity at the boundary, $b(x) \to \infty$ as $x \to x_1$, with the other coefficients being continuous. In this case, the first boundary condition in (M12.5.1.2) should be replaced with a condition of boundedness of the solution as $x \to x_1$. This may occur in spatial problems with central or axial symmetry where the solution depends only on the radial coordinate.

► **Derivation of equations and boundary conditions for particular solutions.** The method of separation of variables is based on searching for particular solutions of equation (M12.5.1.1) in the product form

$$w(x,t) = \varphi(x)\,\psi(t). \qquad \text{(M12.5.1.4)}$$

Let us substitute (M12.5.1.4) into (M12.5.1.1) and divide all terms of the equation by $\varphi(x)\,\psi(t)$. Then we move the terms dependent on t to the left-hand side and those dependent on x to the right-hand side to obtain

$$\frac{\psi'_t}{\psi} - \gamma(t) = \frac{a(x)\varphi''_{xx} + b(x)\varphi'_x + c(x)\varphi}{\varphi}$$

This equality is achieved if both sides are equal to the same constant quantity, $-\lambda$. The free parameter λ is called the *separation constant*. Thus, we arrive at the following linear ordinary differential equations for $\varphi = \varphi(x)$ and $\psi = \psi(t)$:

$$a(x)\varphi''_{xx} + b(x)\varphi'_x + [\lambda + c(x)]\varphi = 0, \qquad \text{(M12.5.1.5)}$$

$$\psi'_t + [\lambda - \gamma(t)]\psi = 0. \qquad \text{(M12.5.1.6)}$$

Substituting (M12.5.1.4) into (M12.5.1.2) yields the boundary conditions for $\varphi = \varphi(x)$:

$$\begin{aligned} s_1\varphi'_x + k_1\varphi = 0 \quad &\text{at} \quad x = x_1,\\ s_2\varphi'_x + k_2\varphi = 0 \quad &\text{at} \quad x = x_2. \end{aligned} \qquad \text{(M12.5.1.7)}$$

The homogeneous linear ordinary differential equation (M12.5.1.5) in conjunction with the homogeneous linear boundary conditions (M12.5.1.7) makes up an eigenvalue problem.

► **Solution of eigenvalue problems. Orthogonality of eigenfunctions.** Let $\widetilde{\varphi}_1(x,\lambda)$ and $\widetilde{\varphi}_2(x,\lambda)$ be linearly independent particular solutions of equation (M12.5.1.5). Then the general solution of this equation can be represented as the linear combination

$$\varphi = C_1\widetilde{\varphi}_1(x,\lambda) + C_2\widetilde{\varphi}_2(x,\lambda), \qquad \text{(M12.5.1.8)}$$

where C_1 and C_2 are arbitrary constants.

Substituting solution (M12.5.1.8) into the boundary conditions (M12.5.1.7) yields the following homogeneous linear algebraic system of equations for C_1 and C_2:

$$\begin{aligned}\sigma_{11}(\lambda)C_1+\sigma_{12}(\lambda)C_2&=0,\\ \sigma_{21}(\lambda)C_1+\sigma_{22}(\lambda)C_2&=0,\end{aligned}\qquad\text{(M12.5.1.9)}$$

where $\sigma_{ij}(\lambda)=\bigl[s_i(\widetilde{\varphi}_j)'_x+k_i\widetilde{\varphi}_j\bigr]_{x=x_i}$. For system (M12.5.1.9) to have nontrivial solutions, its determinant must be zero; we have

$$\sigma_{11}(\lambda)\sigma_{22}(\lambda)-\sigma_{12}(\lambda)\sigma_{21}(\lambda)=0.\qquad\text{(M12.5.1.10)}$$

Solving the transcendental equation (M12.5.1.10) for λ, one obtains the *eigenvalues* $\lambda=\lambda_n$, where $n=1,\ 2,\ \dots$ For these values of λ, equation (M12.5.1.5) has nontrivial solutions,

$$\varphi_n(x)=\sigma_{12}(\lambda_n)\widetilde{\varphi}_1(x,\lambda_n)-\sigma_{11}(\lambda_n)\widetilde{\varphi}_2(x,\lambda_n),\qquad\text{(M12.5.1.11)}$$

which are called *eigenfunctions* (these functions are defined up to a constant multiplier).

To facilitate the further analysis, we represent equation (M12.5.1.5) in the form

$$[p(x)\varphi'_x]'_x+[\lambda\rho(x)-q(x)]\varphi=0,\qquad\text{(M12.5.1.12)}$$

where

$$p(x)=\exp\left[\int\frac{b(x)}{a(x)}\,dx\right],\quad q(x)=-\frac{c(x)}{a(x)}\exp\left[\int\frac{b(x)}{a(x)}\,dx\right],\quad \rho(x)=\frac{1}{a(x)}\exp\left[\int\frac{b(x)}{a(x)}\,dx\right].\qquad\text{(M12.5.1.13)}$$

It follows from the adopted assumptions that $p(x)$, $p'_x(x)$, $q(x)$, and $\rho(x)$ are continuous functions, with $p(x)>0$ and $\rho(x)>0$.

The eigenvalue problem for equation (M12.5.1.12) subject to the boundary conditions (M12.5.1.7) is known to possess the following properties:

1. All eigenvalues $\lambda_1,\ \lambda_2,\ \dots$ are real, and $\lambda_n\to\infty$ as $n\to\infty$; consequently, the number of negative eigenvalues is finite. Each eigenvalue is of multiplicity 1.

2. The system of eigenfunctions $\varphi_1(x),\ \varphi_2(x),\ \dots$ is orthogonal on the interval $x_1\le x\le x_2$ with weight $\rho(x)$, i.e.,

$$\int_{x_1}^{x_2}\rho(x)\varphi_n(x)\varphi_m(x)\,dx=0\quad\text{for}\quad n\neq m.\qquad\text{(M12.5.1.14)}$$

3. If

$$q(x)\ge0,\quad s_1k_1\le0,\quad s_2k_2\ge0,\qquad\text{(M12.5.1.15)}$$

there are no negative eigenvalues. If $q\equiv0$ and $k_1=k_2=0$, the least eigenvalue is $\lambda_1=0$ and the corresponding eigenfunction is $\varphi_1=\text{const}$. Otherwise, all eigenvalues are positive, provided that conditions (M12.5.1.15) are satisfied; the first inequality in (M12.5.1.15) is satisfied if $c(x)\le0$.

Subsection M11.2.4 presents some estimates for the eigenvalues λ_n and eigenfunctions $\varphi_n(x)$.

► **Series solutions of boundary value problems for parabolic equations.** The solution of equation (M12.5.1.1) corresponding to the eigenvalues $\lambda = \lambda_n$ and satisfying the normalizing conditions $\psi_n(0) = 1$ has the form

$$\psi_n(t) = \exp\left[-\lambda_n t + \int_0^t \gamma(\xi)\,d\xi\right]. \qquad \text{(M12.5.1.16)}$$

Then the solution of the nonstationary boundary value problem for equation (M12.5.1.1) with the boundary conditions (M12.5.1.2) and initial condition (M12.5.1.3) is sought in the series form

$$w(x,t) = \sum_{n=1}^{\infty} A_n \varphi_n(x)\,\psi_n(t); \qquad \text{(M12.5.1.17)}$$

the A_n are some constant quantities, whose values are determined in the course of solving the problem. The functions $w_n(x,t) = \varphi_n(x)\,\psi_n(t)$ in (M12.5.1.17) are particular solutions of equation (M12.5.1.1) satisfying the boundary conditions (M12.5.1.2). By the principle of linear superposition, series (M12.5.1.17) is also a solution of the original partial differential equation that satisfies the boundary conditions.

To determine the coefficients A_n, we substitute series (M12.5.1.17) into the initial condition (M12.5.1.3), thus obtaining

$$\sum_{n=1}^{\infty} A_n \varphi_n(x) = f_0(x).$$

Multiplying this equation by $\rho(x)\varphi_n(x)$, where the weight function $\rho(x)$ is defined in (M12.5.1.13), then integrating the resulting relation with respect to x over the interval $x_1 \le x \le x_2$, and taking into account the properties (M12.5.1.14), we find

$$A_n = \frac{1}{\|\varphi_n\|^2} \int_{x_1}^{x_2} \rho(x)\varphi_n(x) f_0(x)\,dx, \qquad \|\varphi_n\|^2 = \int_{x_1}^{x_2} \rho(x)\varphi_n^2(x)\,dx. \qquad \text{(M12.5.1.18)}$$

Relations (M12.5.1.17), (M12.5.1.16), (M12.5.1.11), and (M12.5.1.18) give a formal solution of the nonstationary boundary value problem (M12.5.1.1)–(M12.5.1.3).

Example. Consider the first boundary value problem on the interval $0 \le x \le l$ for the heat equation

$$\frac{\partial w}{\partial t} = \frac{\partial^2 w}{\partial x^2} \qquad \text{(M12.5.1.19)}$$

with the general initial condition (M12.5.1.3) and the homogeneous boundary conditions

$$w = 0 \quad \text{at} \quad x = 0, \qquad w = 0 \quad \text{at} \quad x = l. \qquad \text{(M12.5.1.20)}$$

The functions $\psi_n(t)$ in solution (M12.5.1.17) are found from (M12.5.1.16) where $\gamma(t) = 0$:

$$\psi_n(t) = \exp(-\lambda_n t). \qquad \text{(M12.5.1.21)}$$

The functions $\varphi_n(x)$ are determined by solving the eigenvalue problem (M12.5.1.5), (M12.5.1.7) with $a(x) = 1$, $b(x) = c(x) = 0$, $s_1 = s_2 = 0$, $k_1 = k_2 = 1$, $x_1 = 0$, and $x_2 = l$:

$$\varphi''_{xx} + \lambda\varphi = 0; \qquad \varphi = 0 \quad \text{at} \quad x = 0, \qquad \varphi = 0 \quad \text{at} \quad x = l.$$

So we obtain the eigenfunctions and eigenvalues:

$$\varphi_n(x) = \sin\left(\frac{n\pi x}{l}\right), \qquad \lambda_n = \left(\frac{n\pi}{l}\right)^2, \qquad n = 1,\,2,\,\ldots \qquad \text{(M12.5.1.22)}$$

The solution to problem (M12.5.1.19), (M12.5.1.20), (M12.5.1.3) is given by formulas (M12.5.1.17), (M12.5.1.18), (M12.5.1.21), and (M12.5.1.22). Taking into account that $\|\varphi_n\|^2 = l/2$, we obtain

$$w(x,t) = \sum_{n=1}^{\infty} A_n \sin\left(\frac{n\pi x}{l}\right) \exp\left(-\frac{n^2\pi^2 t}{l^2}\right), \qquad A_n = \frac{2}{l}\int_0^l f_0(\xi)\sin\left(\frac{n\pi\xi}{l}\right)d\xi. \tag{M12.5.1.23}$$

If the function $f_0(x)$ is twice continuously differentiable and the compatibility conditions (see below) are satisfied, then series (M12.5.1.23) is convergent and admits termwise differentiation, once with respect to t and twice with respect to x. In this case, formula (M12.5.1.23) gives the classical smooth solution of problem (M12.5.1.19, (M12.5.1.20), (M12.5.1.3). [If $f_0(x)$ is not as smooth as indicated or if the compatibility conditions are not met, then series (M12.5.1.23) may converge to a discontinuous function, thus giving only a generalized solution.]

► **Conditions of compatibility of initial and boundary conditions.** Suppose the function w has a continuous derivative with respect to t and two continuous derivatives with respect to x and is a solution of problem (M12.5.1.1)–(M12.5.1.3). Then the boundary conditions (M12.5.1.2) and the initial condition (M12.5.1.3) must be consistent; namely, the following compatibility conditions must hold:

$$[s_1 f_0' + k_1 f_0]_{x=x_1} = 0, \quad [s_2 f_0' + k_2 f_0]_{x=x_2} = 0. \tag{M12.5.1.24}$$

If $s_1 = 0$ or $s_2 = 0$, then the additional compatibility conditions

$$\begin{aligned} &[a(x)f_0'' + b(x)f_0']_{x=x_1} = 0 \quad \text{if} \quad s_1 = 0,\\ &[a(x)f_0'' + b(x)f_0']_{x=x_2} = 0 \quad \text{if} \quad s_2 = 0 \end{aligned} \tag{M12.5.1.25}$$

must also hold; the primes denote the derivatives with respect to x.

M12.5.2. Solution of Problems for Hyperbolic Equations

► **Solution of problems by the method of separation of variables.** Consider a linear homogeneous hyperbolic equation of the form

$$\alpha(t)\frac{\partial^2 w}{\partial t^2} + \beta(t)\frac{\partial w}{\partial t} = a(x)\frac{\partial^2 w}{\partial x^2} + b(x)\frac{\partial w}{\partial x} + \big[c(x) + \gamma(t)\big]w \tag{M12.5.2.1}$$

with homogeneous linear boundary conditions (M12.5.1.2) and arbitrary initial conditions,

$$w = f_0(x) \quad \text{at} \quad t = 0, \tag{M12.5.2.2}$$
$$\partial_t w = f_1(x) \quad \text{at} \quad t = 0. \tag{M12.5.2.3}$$

We assume that the coefficients of equation (M12.5.2.1) and boundary conditions (M12.5.1.2) meet the following requirements:

$$\begin{gathered} \alpha(t),\ \beta(t),\ \gamma(t),\ a(x),\ b(x),\ \text{and}\ c(x)\ \text{are continuous functions},\\ \alpha(t) > 0, \quad a(x) > 0, \quad |s_1| + |k_1| > 0, \quad |s_2| + |k_2| > 0. \end{gathered}$$

Let us use the method of separation of variables to solve boundary value problems for homogeneous linear equations of the hyperbolic type (M12.5.2.1) with homogeneous boundary conditions (M12.5.1.2) and nonhomogeneous initial conditions (M12.5.2.2) and (M12.5.2.3).

The approach is based on searching for particular solutions of equation (M12.5.2.1) in the product form (M12.5.1.4). After separating the variables and rearranging (in much the same way as in Subsection M12.5.1 for parabolic equations), one arrives at the following linear ordinary differential equations for the functions $\varphi = \varphi(x)$ and $\psi = \psi(t)$:

$$a(x)\varphi''_{xx} + b(x)\varphi'_x + [\lambda + c(x)]\varphi = 0, \qquad \text{(M12.5.2.4)}$$

$$\alpha(t)\psi''_{tt} + \beta(t)\psi'_t + [\lambda - \gamma(t)]\psi = 0. \qquad \text{(M12.5.2.5)}$$

Note that equation (M12.5.2.4) coincides with (M12.5.1.5).

For hyperbolic equations, the solution of the boundary value problem (M12.5.2.1)–(M12.5.2.3), (M12.5.1.2) is sought in the series form

$$w(x,t) = \sum_{n=1}^{\infty} \varphi_n(x) \left[A_n \psi_{n1}(t) + B_n \psi_{n2}(t)\right]. \qquad \text{(M12.5.2.6)}$$

The A_n and B_n are some constant quantities, whose values are determined further in the course of solving the problem. The functions $\varphi_n(x)$ and the numbers λ_n are determined by solving the eigenvalue problem (M12.5.2.4), (M12.5.1.7). The functions $\psi_{n1}(t)$ and $\psi_{n2}(t)$ are particular solutions of the linear equation (M12.5.2.5) for ψ (with $\lambda = \lambda_n$) that satisfy the conditions

$$\psi_{n1}(0) = 1, \quad \psi'_{n1}(0) = 0; \qquad \psi_{n2}(0) = 0, \quad \psi'_{n2}(0) = 1. \qquad \text{(M12.5.2.7)}$$

Substituting solution (M12.5.2.6) into the initial conditions (M12.5.2.2) and (M12.5.2.3) yields

$$\sum_{n=1}^{\infty} A_n \varphi_n(x) = f_0(x), \qquad \sum_{n=1}^{\infty} B_n \varphi_n(x) = f_1(x).$$

Multiplying these equations by $\rho(x)\varphi_n(x)$, where the weight function $\rho(x)$ is defined in (M12.5.1.13), then integrating the resulting relations with respect to x over the interval $x_1 \le x \le x_2$, and taking into account the properties (M12.5.1.14), we obtain the coefficients of series (M12.5.2.6) in the form

$$A_n = \frac{1}{\|\varphi_n\|^2} \int_{x_1}^{x_2} \rho(x)\varphi_n(x) f_0(x)\,dx, \quad B_n = \frac{1}{\|\varphi_n\|^2} \int_{x_1}^{x_2} \rho(x)\varphi_n(x) f_1(x)\,dx. \qquad \text{(M12.5.2.8)}$$

The quantity $\|\varphi_n\|$ is defined in (M12.5.1.18).

Relations (M12.5.2.6), (M12.5.1.11), and (M12.5.2.8) together with the solutions of the problems for equation (M12.5.2.5) subject to the initial conditions (M12.5.2.7) give a formal solution of the nonstationary boundary value problem for equation (M12.5.2.1) subject to the initial conditions (M12.5.2.2) and (M12.5.2.3) and boundary conditions (M12.5.1.2).

Example. Consider a mixed boundary value problem on the interval $0 \le x \le l$ for the wave equation

$$\frac{\partial^2 w}{\partial t^2} = \frac{\partial^2 w}{\partial x^2} \qquad \text{(M12.5.2.9)}$$

with the general initial conditions (M12.5.2.2) and (M12.5.2.3) and the homogeneous boundary conditions

$$w = 0 \quad \text{at} \quad x = 0, \qquad \partial_x w = 0 \quad \text{at} \quad x = l. \qquad \text{(M12.5.2.10)}$$

The solution of this mixed boundary value problem for equation (M12.5.2.9) is sought in the series form (M12.5.2.6). The functions $\varphi_n(x)$ are determined by solving the eigenvalue problem (M12.5.2.4), (M12.5.1.7) with $a(x) = 1$, $b(x) = c(x) = 0$, $s_1 = k_2 = 0$, $s_2 = k_1 = 1$, $x_1 = 0$, and $x_2 = l$:

$$\varphi''_{xx} + \lambda\varphi = 0; \qquad \varphi = 0 \quad \text{at} \quad x = 0, \qquad \varphi'_x = 0 \quad \text{at} \quad x = l.$$

So we obtain the eigenfunctions and eigenvalues:

$$\varphi_n(x) = \sin(\mu_n x), \quad \mu_n = \sqrt{\lambda_n} = \frac{\pi(2n-1)}{2l}, \quad n = 1,\ 2,\ \dots \tag{M12.5.2.11}$$

The functions $\psi_{n1}(t)$ and $\psi_{n2}(t)$ are determined by the linear equation [see (M12.5.2.5) with $\alpha(t) = 1$, $\beta(t) = \gamma(t) = 0$, and $\lambda = \lambda_n$]

$$\psi''_{tt} + \lambda\psi = 0$$

with the initial conditions (M12.5.2.7). We find

$$\psi_{n1}(t) = \cos\bigl(\sqrt{\lambda_n}\,t\bigr), \quad \psi_{n2}(t) = \frac{1}{\sqrt{\lambda_n}}\sin\bigl(\sqrt{\lambda_n}\,t\bigr). \tag{M12.5.2.12}$$

The solution to problem (M12.5.2.9), (M12.5.2.10), (M12.5.2.2), (M12.5.2.3) is given by formulas (M12.5.2.6), (M12.5.2.11), (M12.5.2.12), and (M12.5.2.8). Taking into account that $\|\varphi_n\|^2 = l/2$, we have

$$\begin{gathered} w(x,t) = \sum_{n=1}^{\infty}\bigl[A_n\cos(\mu_n t) + B_n\sin(\mu_n t)\bigr]\sin(\mu_n x), \quad \mu_n = \frac{\pi(2n-1)}{2l}, \\ A_n = \frac{2}{l}\int_0^l f_0(x)\sin(\mu_n x)\,dx, \quad B_n = \frac{2}{l\mu_n}\int_0^l f_1(x)\sin(\mu_n x)\,dx. \end{gathered} \tag{M12.5.2.13}$$

If $f_0(x)$ and $f_1(x)$ have three and two continuous derivatives, respectively, and the compatibility conditions are met (see below), then series (M12.5.2.13) is convergent and admits double termwise differentiation. In this case, formula (M12.5.2.13) gives the classical smooth solution of problem (M12.5.2.9), (M12.5.2.10), (M12.5.2.2), (M12.5.2.3).

► **Conditions of compatibility of initial and boundary conditions.** Suppose w is a twice continuously differentiable solution of the problem for equation (M12.5.2.1) subject to the initial conditions (M12.5.2.2) and (M12.5.2.3) and boundary conditions (M12.5.1.2). Then conditions (M12.5.1.24) and (M12.5.1.25) must hold. In addition, the following conditions of compatibility of the boundary conditions (M12.5.1.2) and initial condition (M12.5.2.3) must be satisfied:

$$[s_1 f_1' + k_1 f_1]_{x=x_1} = 0, \quad [s_2 f_1' + k_2 f_1]_{x=x_2} = 0.$$

M12.5.3. Solution of Problems for Elliptic Equations

► **Solution of a special problem for elliptic equations.** Now consider a boundary value problem for the elliptic equation

$$a(x)\frac{\partial^2 w}{\partial x^2} + \alpha(y)\frac{\partial^2 w}{\partial y^2} + b(x)\frac{\partial w}{\partial x} + \beta(y)\frac{\partial w}{\partial y} + \bigl[c(x) + \gamma(y)\bigr]w = 0 \tag{M12.5.3.1}$$

with homogeneous linear boundary conditions (M12.5.1.2) in x and the following mixed (homogeneous and nonhomogeneous) boundary conditions in y:

$$\begin{aligned} \sigma_1\partial_y w + \nu_1 w &= 0 && \text{at} \quad y = y_1, \\ \sigma_2\partial_y w + \nu_2 w &= f(x) && \text{at} \quad y = y_2. \end{aligned} \tag{M12.5.3.2}$$

We assume that the coefficients of equation (M12.5.3.1) and boundary conditions (M12.5.1.2) and (M12.5.3.2) meet the following requirements:

$$\begin{gathered} a(x),\ b(x),\ c(x)\ \alpha(y),\ \beta(y),\ \text{and}\ \gamma(y)\ \text{are continuous functions,} \\ a(x) > 0,\ \alpha(y) > 0,\ |s_1| + |k_1| > 0,\ |s_2| + |k_2| > 0,\ |\sigma_1| + |\nu_1| > 0,\ |\sigma_2| + |\nu_2| > 0. \end{gathered}$$

The method of separation of variables is based on searching for particular solutions of equation (M12.5.3.1) in the product form

$$w(x,y)=\varphi(x)\,\psi(y). \qquad \text{(M12.5.3.3)}$$

As before, we first arrive at the eigenvalue problem (M12.5.1.5), (M12.5.1.7) for the function $\varphi=\varphi(x)$; the solution procedure is detailed in Subsection M12.5.1. Further on, we assume that the λ_n and $\varphi_n(x)$ have been found. The functions $\psi_n=\psi_n(y)$ are determined by solving the linear ordinary differential equation

$$\alpha(y)\psi''_{yy}+\beta(y)\psi'_y+[\gamma(y)-\lambda_n]\psi=0 \qquad \text{(M12.5.3.4)}$$

subject to the homogeneous boundary condition

$$\sigma_1\partial_y\psi+\nu_1\psi=0 \quad \text{at} \quad y=y_1, \qquad \text{(M12.5.3.5)}$$

which follows from the first condition in (M12.5.3.2). The functions ψ_n are determined up to a constant factor.

Taking advantage of the principle of linear superposition, we seek the solution to the boundary value problem (M12.5.3.1), (M12.5.3.2), (M12.5.1.2) in the series form

$$w(x,y)=\sum_{n=1}^{\infty}A_n\varphi_n(x)\psi_n(y); \qquad \text{(M12.5.3.6)}$$

The A_n are some constants, which are to be determined. By construction, series (M12.5.3.6) will satisfy equation (M12.5.3.1) with the boundary conditions (M12.5.1.2) and the first boundary condition (M12.5.3.2). In order to find the coefficients A_n, substitute (M12.5.3.6) into the second boundary condition (M12.5.3.2) to obtain

$$\sum_{n=1}^{\infty}A_nB_n\varphi_n(x)=f(x), \qquad B_n=\sigma_2\frac{d\psi_n}{dy}\bigg|_{y=y_2}+\nu_2\psi_n(y_2). \qquad \text{(M12.5.3.7)}$$

Further, we follow the same procedure as in Subsection M12.5.1. Specifically, multiplying (M12.5.3.7) by $\rho(x)\varphi_n(x)$, then integrating the resulting relation with respect to x over the interval $x_1\le x\le x_2$ and taking into account the properties (M12.5.1.14), we obtain

$$A_n=\frac{1}{B_n\|\varphi_n\|^2}\int_{x_1}^{x_2}\rho(x)\varphi_n(x)f(x)\,dx, \quad \|\varphi_n\|^2=\int_{x_1}^{x_2}\rho(x)\varphi_n^2(x)\,dx, \qquad \text{(M12.5.3.8)}$$

where the weight function $\rho(x)$ is defined in (M12.5.1.13).

Example. Consider the first (Dirichlet) boundary value problem for the Laplace equation

$$\frac{\partial^2 w}{\partial x^2}+\frac{\partial^2 w}{\partial y^2}=0 \qquad \text{(M12.5.3.9)}$$

subject to the boundary conditions

$$\begin{aligned} &w=0 \quad \text{at} \quad x=0, \qquad w=0 \quad \text{at} \quad x=l_1;\\ &w=0 \quad \text{at} \quad y=0, \qquad w=f(x) \quad \text{at} \quad y=l_2 \end{aligned} \qquad \text{(M12.5.3.10)}$$

in a rectangular domain $0\le x\le l_1$, $0\le y\le l_2$.

Particular solutions to equation (M12.5.3.9) are sought in the form (M12.5.3.3). We have the following eigenvalue problem for $\varphi(x)$:

$$\varphi''_{xx} + \lambda\varphi = 0; \qquad \varphi = 0 \quad \text{at} \quad x = 0, \qquad \varphi = 0 \quad \text{at} \quad x = l_1.$$

On solving this problem, we find the eigenfunctions with respective eigenvalues

$$\varphi_n(x) = \sin(\mu_n x), \qquad \mu_n = \sqrt{\lambda_n} = \frac{\pi n}{l_1}, \qquad n = 1,\, 2,\, \ldots \tag{M12.5.3.11}$$

The functions $\psi_n = \psi_n(y)$ are determined by solving the following problem for a linear ordinary differential equation with homogeneous boundary conditions (at this stage, the functions ψ_n are determined up to a constant factor each):

$$\psi''_{yy} - \lambda_n\psi = 0; \qquad \psi = 0 \quad \text{at} \quad y = 0. \tag{M12.5.3.12}$$

It is a special case of problem (M12.5.3.4), (M12.5.3.5) with $\alpha(y) = 1$, $\beta(y) = \gamma(y) = 0$, $\sigma_1 = 0$, and $\nu_1 = 1$. The nontrivial solutions of problem (M12.5.3.12) are expressed as

$$\psi_n(y) = \sinh(\mu_n y), \qquad \mu_n = \sqrt{\lambda_n} = \frac{\pi n}{l_1}, \qquad n = 1,\, 2,\, \ldots \tag{M12.5.3.13}$$

Using formulas (M12.5.3.6), (M12.5.3.8), (M12.5.3.11), (M12.5.3.13) and taking into account the relations $B_n = \psi_n(l_2) = \sinh(\mu_n l_2)$, $\rho(x) = 1$, and $\|\varphi_n\|^2 = l_1/2$, we find the solution of the original problem (M12.5.3.9), (M12.5.3.10) in the form

$$w(x,y) = \sum_{n=1}^{\infty} A_n \sin(\mu_n x)\sinh(\mu_n y), \qquad A_n = \frac{2}{l_1 \sinh(\mu_n l_2)} \int_0^{l_1} f(x)\sin(\mu_n x)\,dx, \qquad \mu_n = \frac{\pi n}{l_1}.$$

► **Generalization to the case of nonhomogeneous boundary conditions.** Now consider the linear boundary value problem for the elliptic equation (M12.5.3.1) with general nonhomogeneous boundary conditions

$$\begin{aligned} &s_1\partial_x w + k_1 w = f_1(y) \quad \text{at} \quad x = x_1, \qquad s_2\partial_x w + k_2 w = f_2(y) \quad \text{at} \quad x = x_2, \\ &\sigma_1\partial_y w + \nu_1 w = f_3(x) \quad \text{at} \quad y = y_1, \qquad \sigma_2\partial_y w + \nu_2 w = f_4(x) \quad \text{at} \quad y = y_2. \end{aligned} \tag{M12.5.3.14}$$

The solution to this problem is the sum of solutions to four simpler auxiliary problems for equation (M12.5.3.1), each corresponding to one nonhomogeneous and three homogeneous boundary conditions in (M12.5.3.14); in these problems, all but one of the functions f_n are zero. Each auxiliary problem is solved using the procedure described above in this subsection, beginning with the search for solutions in the form of the product of functions with different arguments (M12.5.3.3), determined by equations (M12.5.1.5) and (M12.5.3.4). The solution to each of the auxiliary problems is sought in the series form (M12.5.3.6).

M12.6. Integral Transforms Method

Various integral transforms are widely used to solve linear problems of mathematical physics. The Laplace transform and the Fourier transform are in most common use (these and other integral transforms are considered in Chapter M10 in detail).

M12.6.1. Laplace Transform and Its Application to Linear Mathematical Physics Equations

► **Laplace and inverse Laplace transforms. Laplace transforms for derivatives.** The Laplace transform of an arbitrary (complex-valued) function $f(t)$ of a real variable t ($t \ge 0$) is defined by

$$\widetilde{f}(p) = \mathfrak{L}\bigl\{f(t)\bigr\}, \quad \text{where} \quad \mathfrak{L}\bigl\{f(t)\bigr\} \equiv \int_0^{\infty} e^{-pt} f(t)\,dt, \tag{M12.6.1.1}$$

where $p = s + i\sigma$ is a complex variable, $i^2 = -1$.

Given the transform $\widetilde{f}(p)$, the function $f(t)$ can be found by means of the inverse Laplace transform

$$f(t) = \mathfrak{L}^{-1}\bigl\{\widetilde{f}(p)\bigr\}, \quad \text{where} \quad \mathfrak{L}^{-1}\bigl\{\widetilde{f}(p)\bigr\} \equiv \frac{1}{2\pi i}\int_{c-i\infty}^{c+i\infty} \widetilde{f}(p)e^{pt}\,dp, \tag{M12.6.1.2}$$

where the integration path is parallel to the imaginary axis and lies to the right of all singularities of $\widetilde{f}(p)$.

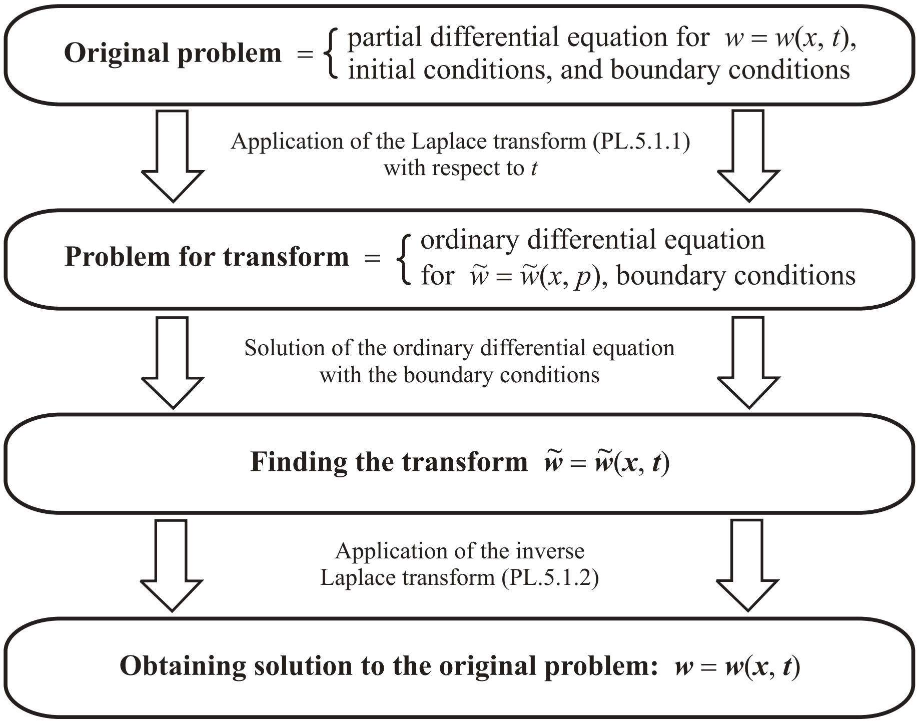
In order to solve nonstationary boundary value problems, the following Laplace transform formulas for derivatives will be required:

$$\begin{aligned} \mathfrak{L}\bigl\{f'(t)\bigr\} &= p\widetilde{f}(p) - f(0), \\ \mathfrak{L}\bigl\{f''(t)\bigr\} &= p^2\widetilde{f}(p) - pf(0) - f'(0), \end{aligned} \tag{M12.6.1.3}$$

where $f(0)$ and $f'(0)$ are the initial values.

More details on the properties of the Laplace transform and the inverse Laplace transform can be found in Section M10.2. The Laplace transforms of some functions are listed in Section S2.1. Tables of inverse Laplace transforms are listed in Section S2.2. Such tables are convenient to use when solving linear problems for partial differential equations.

► **Solution procedure for linear problems using the Laplace transform.** Figure M12.1 shows schematically how one can utilize the Laplace transforms to solve boundary value problems for linear parabolic or hyperbolic equations with two independent variables in the case where the equation coefficients are independent of t (the same procedure can be applied to solving linear problems characterized by higher-order equations). Here and henceforth, the short notation $\widetilde{w}(x,p) = \mathfrak{L}\{w(x,t)\}$ will be used; the arguments of $\widetilde{w}$ may be omitted.



Original problem = { partial differential equation for $w = w(x, t)$, initial conditions, and boundary conditions
Application of the Laplace transform (PL.5.1.1) with respect to t
Problem for transform = { ordinary differential equation for $\widetilde{w} = \widetilde{w}(x, p)$, boundary conditions
Solution of the ordinary differential equation with the boundary conditions
Finding the transform $\widetilde{w} = \widetilde{w}(x, t)$
Application of the inverse Laplace transform (PL.5.1.2)
Obtaining solution to the original problem: $w = w(x, t)$

Figure M12.1. Solution procedure for linear boundary value problems using the Laplace transform.

It is significant that with the Laplace transform, the original problem for a partial differential equation is reduced to a simpler problem for an ordinary differential equation with parameter p; the derivatives with respect to t are replaced by appropriate algebraic expressions taking into account the initial conditions; see formulas (M12.6.1.3).

► **Solving linear problems for parabolic equations using the Laplace transform.** Consider a linear nonstationary boundary value problem for the parabolic equation

$$\frac{\partial w}{\partial t} = a(x)\frac{\partial^2 w}{\partial x^2} + b(x)\frac{\partial w}{\partial x} + c(x)w + \Phi(x,t) \tag{M12.6.1.4}$$

with the initial condition (M12.5.1.3) and the general nonhomogeneous boundary conditions

$$\begin{aligned} s_1\partial_x w + k_1 w &= g_1(t) \quad \text{at} \quad x = x_1, \\ s_2\partial_x w + k_2 w &= g_2(t) \quad \text{at} \quad x = x_2. \end{aligned} \tag{M12.6.1.5}$$

The application of the Laplace transform (M12.6.1.1) results in the problem determined by the ordinary differential equation for x (p is treated as a parameter)

$$a(x)\widetilde{w}''_{xx} + b(x)\widetilde{w}'_x + [c(x) - p]\widetilde{w} + f_0(x) + \widetilde{\Phi}(x,p) = 0 \tag{M12.6.1.6}$$

with the boundary conditions

$$\begin{aligned} s_1\widetilde{w}'_x + k_1\widetilde{w} &= \widetilde{g}_1(p) \quad \text{at} \quad x = x_1, \\ s_2\widetilde{w}'_x + k_2\widetilde{w} &= \widetilde{g}_2(p) \quad \text{at} \quad x = x_2. \end{aligned} \tag{M12.6.1.7}$$

Notation used: $\widetilde{\Phi}(x,p) = \mathfrak{L}\{\Phi(x,t)\}$ and $\widetilde{g}_n(p) = \mathfrak{L}\{g_n(t)\}$ ($n = 1,\ 2$). On solving problem (M12.6.1.6), (M12.6.1.7), one should apply to the resulting solution $\widetilde{w} = \widetilde{w}(x,p)$ the inverse Laplace transform (M12.6.1.2) to obtain the solution, $w = w(x,t)$, of the original problem.

Example. Consider the first boundary value problem for the heat equation:

$$\begin{aligned} &\frac{\partial w}{\partial t} = \frac{\partial^2 w}{\partial x^2} && (x > 0,\ t > 0), \\ &w = 0 \quad \text{at} \quad t = 0 && \text{(initial condition)}, \\ &w = w_0 \quad \text{at} \quad x = 0 && \text{(boundary condition)}, \\ &w \to 0 \quad \text{at} \quad x \to \infty && \text{(boundary condition)}. \end{aligned}$$

We apply the Laplace transform with respect to t. Let us multiply the equation, the initial condition, and the boundary conditions by e^{-pt} and then integrate with respect to t from zero to infinity. Taking into account the relations

$\mathfrak{L}\{\partial_t w\} = p\widetilde{w} - w|_{t=0} = p\widetilde{w}$ (used are first property (M12.6.1.3) and the initial condition),

$\mathfrak{L}\{w_0\} = w_0\mathfrak{L}\{1\} = w_0/p$ (used are the first property of Subsection S2.1.1 and the relation $\mathfrak{L}\{1\} = 1/p$),

we arrive at the following problem for a second-order linear ordinary differential equation with parameter p:

$$\begin{aligned} &\widetilde{w}''_{xx} - p\widetilde{w} = 0, \\ &\widetilde{w} = w_0/p \quad \text{at} \quad x = 0 && \text{(boundary condition)}, \\ &\widetilde{w} \to 0 \quad \text{at} \quad x \to \infty && \text{(boundary condition)}. \end{aligned}$$

Integrating the equation yields the general solution $\widetilde{w} = A_1(p)e^{-x\sqrt{p}} + A_2(p)e^{x\sqrt{p}}$. Using the boundary conditions, we determine the constants, $A_1(p) = w_0/p$ and $A_2(p) = 0$. Thus, we have

$$\widetilde{w} = \frac{w_0}{p}e^{-x\sqrt{p}}.$$

Let us apply the inverse Laplace transform to both sides of this relation. We refer to the table in Subsection S2.2.5, row 20 (where x must be replaced by t and then a by x^2), to find the inverse transform of the right-hand side. Finally, we obtain the solution of the original problem:

$$w = w_0 \operatorname{erfc}\left(\frac{x}{2\sqrt{t}}\right), \qquad \text{where} \quad \operatorname{erfc} z = \frac{2}{\sqrt{\pi}}\int_z^\infty \exp\left(-\xi^2\right) d\xi.$$

M12.6.2. Fourier Transform and Its Application for Linear Equations of Mathematical Physics

► **Fourier transform and its properties.** The Fourier transform is defined as follows:

$$\widetilde{f}(u) = \mathfrak{F}\bigl\{f(x)\bigr\}, \quad \text{where} \quad \mathfrak{F}\bigl\{f(x)\bigr\} \equiv \frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty} f(x)e^{-iux}\,dx, \qquad i^2 = -1. \tag{M12.6.2.1}$$

This relation is meaningful for any function $f(x)$ absolutely integrable on the interval $(-\infty, \infty)$.

Given $\widetilde{f}(u)$, the function $f(x)$ can be found by means of the inverse Fourier transform

$$f(x) = \mathfrak{F}^{-1}\bigl\{\widetilde{f}(u)\bigr\}, \quad \text{where} \quad \mathfrak{F}^{-1}\bigl\{\widetilde{f}(u)\bigr\} \equiv \frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty} \widetilde{f}(u)e^{iux}\,du, \tag{M12.6.2.2}$$

where the integral is understood in the sense of the Cauchy principal value.

The main properties of the correspondence between functions and their Fourier transforms are gathered in Table M10.4.

► **Solving linear problems of mathematical physics by the Fourier transform.** The Fourier transform is usually employed to solve problems for linear partial differential equations whose coefficients are independent of the space variable x, $-\infty < x < \infty$.

The scheme for solving linear boundary value problems with the help of the Fourier transform is similar to that used in solving problems with the help of the Laplace transform. With the Fourier transform, the derivatives with respect to x in the equation are replaced by appropriate algebraic expressions; see Property 4 or 5 in Table M10.4. In the case of two independent variables, the problem for a partial differential equation is reduced to a simpler problem for an ordinary differential equation with parameter u. On solving the latter problem, one determines the transform. After that, by applying the inverse Fourier transform, one obtains the solution of the original boundary value problem.

Example. Consider the following Cauchy problem for the heat equation:

$$\begin{aligned} &\frac{\partial w}{\partial t} = \frac{\partial^2 w}{\partial x^2} && (-\infty < x < \infty), \\ &w = f(x) \quad \text{at} \quad t = 0 && \text{(initial condition).} \end{aligned}$$

We apply the Fourier transform with respect to the space variable x. Setting $\widetilde{w} = \mathfrak{F}\{w(x,t)\}$ and taking into account the relation $\mathfrak{F}\{\partial_{xx}w\} = -u^2\widetilde{w}$ (see Property 4 in Table M10.4), we arrive at the following problem for a linear first-order ordinary differential equation in t with parameter u:

$$\begin{aligned} &\widetilde{w}'_t + u^2\widetilde{w} = 0, \\ &\widetilde{w} = \widetilde{f}(u) \quad \text{at} \quad t = 0, \end{aligned}$$

where $\widetilde{f}(u)$ is defined by (M12.6.2.1). On solving this problem for the transform $\widetilde{w}$, we find

$$\widetilde{w} = \widetilde{f}(u)e^{-u^2 t}.$$

Let us apply the inversion formula to both sides of this equation. After some calculations, we obtain the solution of the original problem in the form

$$\begin{aligned} w &= \frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty} \widetilde{f}(u)e^{-u^2 t}e^{iux}\,du = \frac{1}{2\pi}\int_{-\infty}^{\infty}\left[\int_{-\infty}^{\infty} f(\xi)e^{-iu\xi}d\xi\right]e^{-u^2 t + iux}du \\ &= \frac{1}{2\pi}\int_{-\infty}^{\infty} f(\xi)\,d\xi\int_{-\infty}^{\infty} e^{-u^2 t + iu(x-\xi)}du = \frac{1}{\sqrt{2\pi t}}\int_{-\infty}^{\infty} f(\xi)\exp\left[-\frac{(x-\xi)^2}{4t}\right]d\xi. \end{aligned}$$

At the last stage we used the relation $\displaystyle\int_{-\infty}^{\infty}\exp\bigl(-a^2u^2 + bu\bigr)\,du = \frac{\sqrt{\pi}}{|a|}\exp\left(\frac{b^2}{4a^2}\right)$.

M12.7. Boundary Value Problems for Parabolic Equations with One Space Variable. Green's Function

M12.7.1. Representation of Solutions via the Green's Function

► **Statement of the problem $(t \geq 0,\ x_1 \leq x \leq x_2)$.** In general, a nonhomogeneous linear differential equation of the parabolic type with variable coefficients with one spatial coordinate can be written as

$$\frac{\partial w}{\partial t} - L_{x,t}[w] = \Phi(x,t), \qquad \text{(M12.7.1.1)}$$

where

$$L_{x,t}[w] \equiv a(x,t)\frac{\partial^2 w}{\partial x^2} + b(x,t)\frac{\partial w}{\partial x} + c(x,t)w, \qquad a(x,t) > 0. \qquad \text{(M12.7.1.2)}$$

Consider the nonstationary boundary value problem for equation (M12.7.1.1) with an initial condition of general form

$$w = f(x) \quad \text{at} \quad t = 0, \qquad \text{(M12.7.1.3)}$$

and arbitrary nonhomogeneous linear boundary conditions

$$s_1\frac{\partial w}{\partial x} + k_1 w = g_1(t) \quad \text{at} \quad x = x_1, \qquad \text{(M12.7.1.4)}$$

$$s_2\frac{\partial w}{\partial x} + k_2 w = g_2(t) \quad \text{at} \quad x = x_2. \qquad \text{(M12.7.1.5)}$$

By appropriately choosing the coefficients s_1, s_2, k_1, and k_2 in (M12.7.1.4) and (M12.7.1.5), one arrives at the first, second, third, and mixed boundary value problems for equation (M12.7.1.1).

► **Representation of the problem solution in terms of the Green's function.** The solution of the nonhomogeneous linear boundary value problem (M12.7.1.1)–(M12.7.1.5) can be represented as

$$\begin{aligned} w(x,t) = &\int_0^t \int_{x_1}^{x_2} \Phi(y,\tau)G(x,y,t,\tau)\,dy\,d\tau + \int_{x_1}^{x_2} f(y)G(x,y,t,0)\,dy \\ &+ \int_0^t g_1(\tau)a(x_1,\tau)\Lambda_1(x,t,\tau)\,d\tau + \int_0^t g_2(\tau)a(x_2,\tau)\Lambda_2(x,t,\tau)\,d\tau. \end{aligned} \qquad \text{(M12.7.1.6)}$$

Here, $G(x,y,t,\tau)$ is the Green's function that satisfies, for $t > \tau \geq 0$, the homogeneous equation

$$\frac{\partial G}{\partial t} - L_{x,t}[G] = 0 \qquad \text{(M12.7.1.7)}$$

with the nonhomogeneous initial condition of a special form

$$G = \delta(x-y) \quad \text{at} \quad t = \tau \qquad \text{(M12.7.1.8)}$$

TABLE M12.4
Expressions of the functions $\Lambda_1(x,t,\tau)$ and $\Lambda_2(x,t,\tau)$ involved in the integrands of the last two terms in solution (M12.7.1.6).

Type of problem	Form of boundary conditions	Functions $\Lambda_m(x,t,\tau)$
First boundary value problem $(s_1=s_2=0,\ k_1=k_2=1)$	$w=g_1(t)$ at $x=x_1$ $w=g_2(t)$ at $x=x_2$	$\Lambda_1(x,t,\tau)=\partial_y G(x,y,t,\tau)\big\|_{y=x_1}$ $\Lambda_2(x,t,\tau)=-\partial_y G(x,y,t,\tau)\big\|_{y=x_2}$
Second boundary value problem $(s_1=s_2=1,\ k_1=k_2=0)$	$\partial_x w=g_1(t)$ at $x=x_1$ $\partial_x w=g_2(t)$ at $x=x_2$	$\Lambda_1(x,t,\tau)=-G(x,x_1,t,\tau)$ $\Lambda_2(x,t,\tau)=G(x,x_2,t,\tau)$
Third boundary value problem $(s_1=s_2=1,\ k_1<0,\ k_2>0)$	$\partial_x w+k_1w=g_1(t)$ at $x=x_1$ $\partial_x w+k_2w=g_2(t)$ at $x=x_2$	$\Lambda_1(x,t,\tau)=-G(x,x_1,t,\tau)$ $\Lambda_2(x,t,\tau)=G(x,x_2,t,\tau)$
Mixed boundary value problem $(s_1=k_2=0,\ s_2=k_1=1)$	$w=g_1(t)$ at $x=x_1$ $\partial_x w=g_2(t)$ at $x=x_2$	$\Lambda_1(x,t,\tau)=\partial_y G(x,y,t,\tau)\big\|_{y=x_1}$ $\Lambda_2(x,t,\tau)=G(x,x_2,t,\tau)$
Mixed boundary value problem $(s_1=k_2=1,\ s_2=k_1=0)$	$\partial_x w=g_1(t)$ at $x=x_1$ $w=g_2(t)$ at $x=x_2$	$\Lambda_1(x,t,\tau)=-G(x,x_1,t,\tau)$ $\Lambda_2(x,t,\tau)=-\partial_y G(x,y,t,\tau)\big\|_{y=x_2}$

and the homogeneous boundary conditions

$$s_1\frac{\partial G}{\partial x}+k_1G=0 \quad \text{at} \quad x=x_1, \tag{M12.7.1.9}$$

$$s_2\frac{\partial G}{\partial x}+k_2G=0 \quad \text{at} \quad x=x_2. \tag{M12.7.1.10}$$

The quantities y and τ appear in problem (M12.7.1.7)–(M12.7.1.10) as free parameters, with $x_1\le y\le x_2$, and $\delta(x)$ is the Dirac delta function.

The initial condition (M12.7.1.8) implies the limit relation

$$f(x)=\lim_{t\to\tau}\int_{x_1}^{x_2} f(y)G(x,y,t,\tau)\,dy$$

for any continuous function $f=f(x)$.

The functions $\Lambda_1(x,t,\tau)$ and $\Lambda_2(x,t,\tau)$ involved in the integrands of the last two terms in solution (M12.7.1.6) can be expressed in terms of the Green's function $G(x,y,t,\tau)$. The corresponding formulas for $\Lambda_m(x,t,\tau)$ are given in Table M12.4 for the basic types of boundary value problems.

It is significant that the Green's function G and the functions Λ_1, Λ_2 are independent of the functions Φ, f, g_1, and g_2 that characterize various nonhomogeneities of the boundary value problem.

If the coefficients of equation (M12.7.1.1)–(M12.7.1.2) are independent of time t, i.e., the conditions

$$a=a(x), \quad b=b(x), \quad c=c(x) \tag{M12.7.1.11}$$

hold, then the Green's function depends on only three arguments,

$$G(x,y,t,\tau)=G(x,y,t-\tau). \tag{M12.7.1.12}$$

In this case, the functions Λ_m depend on only two arguments, $\Lambda_m=\Lambda_m(x,t-\tau)$, $m=1,\ 2$.

Formula (M12.7.1.6) also remains valid for the problem with boundary conditions of the third kind if $k_1=k_1(t)$ and $k_2=k_2(t)$. Here, the relations between Λ_m ($m=1,\ 2$) and the Green's function G are the same as in the case of constant k_1 and k_2; the Green's function itself is now different.

Remark. In the first, second, and third boundary value problems that are considered on the interval $x_1 \le x < \infty$, a condition of boundedness of the solution as $x \to \infty$ is set out. In this case, the solution is calculated by formula (M12.7.1.6) with $\Lambda_2 = 0$ and Λ_1 specified in Table M12.4.

► **Formulas for calculating Green's functions.** Consider the parabolic equation of a special form

$$\frac{\partial w}{\partial t} = a(x)\frac{\partial^2 w}{\partial x^2} + b(x)\frac{\partial w}{\partial x} + \bigl[c(x) + \gamma(t)\bigr]w + \Phi(x,t), \qquad \text{(M12.7.1.13)}$$

which is a special case of equation (M12.7.1.1) with operator (M12.7.1.2) where $a(x,t) = a(x)$, $b(x,t) = b(x)$, and $c(x,t) = c(x) + \gamma(t)$. It is assumed that $a(x) > 0$.

The solution of the nonhomogeneous linear boundary value problem (M12.7.1.13), (M12.7.1.2)–(M12.7.1.5) is found by formula (M12.7.1.6), where the Green's function is given by

$$G(x,y,t,\tau) = \rho(y)\sum_{n=1}^{\infty}\frac{\varphi_n(x)\varphi_n(y)}{\|\varphi_n\|^2}\exp\biggl[-\lambda_n(t-\tau) + \int_\tau^t \gamma(\xi)\,d\xi\biggr], \qquad \text{(M12.7.1.14)}$$

where the λ_n and $\varphi_n(x)$ are the eigenvalues and the corresponding eigenfunctions of the Sturm–Liouville problem for the linear ordinary differential equation (M12.5.1.5) with the homogeneous linear boundary conditions (M12.5.1.7), and

$$\rho(y) = \frac{1}{a(y)}\exp\biggl[\int \frac{b(y)}{a(y)}\,dy\biggr], \qquad \|\varphi_n\|^2 = \int_{x_1}^{x_2}\rho(x)\varphi_n^2(x)\,dx, \qquad \text{(M12.7.1.15)}$$

Table M12.5 lists Green's functions for some problems for the nonhomogeneous heat equation that corresponds to $a(x) = a = \text{const}$ and $b(x) = c(x) = \gamma(t) \equiv 0$ in (M12.7.1.13). The function $G(x,y,t-\tau)$ from this table must be substituted for $G(x,y,t,\tau)$ in formula (M12.7.1.6).

M12.7.2. Problems for Parabolic Equation $\rho(x)\frac{\partial w}{\partial t} = \frac{\partial}{\partial x}\Bigl[p(x)\frac{\partial w}{\partial x}\Bigr] - q(x)w + \Phi(x,t)$

► **General formulas for solving nonhomogeneous boundary value problems.** Consider a linear parabolic equation of the special form

$$\rho(x)\frac{\partial w}{\partial t} = \frac{\partial}{\partial x}\biggl[p(x)\frac{\partial w}{\partial x}\biggr] - q(x)w + \Phi(x,t). \qquad \text{(M12.7.2.1)}$$

It is often encountered in heat and mass transfer theory and chemical engineering sciences. Throughout this subsection, we assume that the functions ρ, p, p'_x, and q are continuous and $\rho > 0$, $p > 0$, and $x_1 \le x \le x_2$.

The solution of equation (M12.7.2.1) under the initial condition (M12.7.1.3) and the arbitrary linear nonhomogeneous boundary conditions (M12.7.1.4) and (M12.7.1.5) can be represented as the sum

$$\begin{aligned} w(x,t) &= \int_0^t\int_{x_1}^{x_2}\Phi(y,\tau)\mathcal{G}(x,y,t-\tau)\,dy\,d\tau + \int_{x_1}^{x_2}\rho(y)f(y)\mathcal{G}(x,y,t)\,dy \\ &\quad + p(x_1)\int_0^t g_1(\tau)\Lambda_1(x,t-\tau)\,d\tau + p(x_2)\int_0^t g_2(\tau)\Lambda_2(x,t-\tau)\,d\tau. \end{aligned} \qquad \text{(M12.7.2.2)}$$

TABLE M12.5
The Green's functions for some boundary value problems for the heat equation.

Type of problem	Green's function, $G(x,y,t)$	Remarks
First boundary value problem ($0\le x<\infty$)	$\frac{1}{2\sqrt{\pi at}}\Bigl\{\exp\Bigl[-\frac{(x-y)^2}{4at}\Bigr]-\exp\Bigl[-\frac{(x+y)^2}{4at}\Bigr]\Bigr\}$	Looking for solution bounded as $x\to\infty$
Second boundary value problem ($0\le x<\infty$)	$\frac{1}{2\sqrt{\pi at}}\Bigl\{\exp\Bigl[-\frac{(x-y)^2}{4at}\Bigr]+\exp\Bigl[-\frac{(x+y)^2}{4at}\Bigr]\Bigr\}$	Looking for solution bounded as $x\to\infty$
First boundary value problem ($0\le x\le l$)	$\frac{2}{l}\sum_{n=1}^{\infty}\sin\Bigl(\frac{n\pi x}{l}\Bigr)\sin\Bigl(\frac{n\pi y}{l}\Bigr)\exp\Bigl(-\frac{an^2\pi^2t}{l^2}\Bigr)$ $=\frac{1}{2\sqrt{\pi at}}\sum_{n=-\infty}^{\infty}\Bigl\{\exp\Bigl[-\frac{(x-y+2nl)^2}{4at}\Bigr]-\exp\Bigl[-\frac{(x+y+2nl)^2}{4at}\Bigr]\Bigr\}$	The first series converges rapidly at large t and the second series at small t
Second boundary value problem ($0\le x\le l$)	$\frac{1}{l}+\frac{2}{l}\sum_{n=1}^{\infty}\cos\Bigl(\frac{n\pi x}{l}\Bigr)\cos\Bigl(\frac{n\pi y}{l}\Bigr)\exp\Bigl(-\frac{an^2\pi^2t}{l^2}\Bigr)$ $=\frac{1}{2\sqrt{\pi at}}\sum_{n=-\infty}^{\infty}\Bigl\{\exp\Bigl[-\frac{(x-y+2nl)^2}{4at}\Bigr]+\exp\Bigl[-\frac{(x+y+2nl)^2}{4at}\Bigr]\Bigr\}$	The first series converges rapidly at large t and the second series at small t
Mixed boundary value problem ($0\le x\le l$); w set at $x=0$ and $\partial_x w$ set at $x=l$	$\frac{2}{l}\sum_{n=0}^{\infty}\sin\Bigl[\frac{\pi(2n+1)x}{2l}\Bigr]\sin\Bigl[\frac{\pi(2n+1)y}{2l}\Bigr]\exp\Bigl[-\frac{a\pi^2(2n+1)^2t}{4l^2}\Bigr]$ $=\frac{1}{2\sqrt{\pi at}}\sum_{n=-\infty}^{\infty}(-1)^n\Bigl\{\exp\Bigl[-\frac{(x-y+2nl)^2}{4at}\Bigr]-\exp\Bigl[-\frac{(x+y+2nl)^2}{4at}\Bigr]\Bigr\}$	The first series converges rapidly at large t and the second series at small t

Here, the modified Green's function is given by

$$\mathcal{G}(x,y,t)=\sum_{n=1}^{\infty}\frac{\varphi_n(x)\varphi_n(y)}{\|\varphi_n\|^2}\exp(-\lambda_n t),\qquad \|\varphi_n\|^2=\int_{x_1}^{x_2}\rho(x)\varphi_n^2(x)\,dx,\quad \text{(M12.7.2.3)}$$

where the λ_n and $\varphi_n(x)$ are the eigenvalues and corresponding eigenfunctions of the following Sturm–Liouville problem for a second-order linear ordinary differential equation:

$$\begin{aligned}&[p(x)\varphi'_x]'_x+[\lambda\rho(x)-q(x)]\varphi=0,\\ &s_1\varphi'_x+k_1\varphi=0\quad\text{at}\quad x=x_1,\\ &s_2\varphi'_x+k_2\varphi=0\quad\text{at}\quad x=x_2.\end{aligned}\qquad \text{(M12.7.2.4)}$$

The functions $\Lambda_1(x,t)$ and $\Lambda_2(x,t)$ that occur in the integrands of the last two terms in solution (M12.7.2.2) are expressed in terms of the Green's function (M12.7.2.3).

Remark. The corresponding formulas for $\Lambda_m(x,t)$ for the basic types of boundary value problems can be obtained from Table M12.4; to do so, one should set $G=\mathcal{G}$ in all formulas of the last column and omit the last argument τ.

► **Properties of Sturm–Liouville problem (M12.7.2.4). Heat equation with a source.** The basic properties of the Sturm–Liouville problem (M12.7.2.4), which coincides with problem (M12.5.1.12), (M12.5.1.7), are outlined in Subsections M12.5.1 and M11.2.4. In particular, there are infinitely many eigenvalues. All eigenvalues are real and different and can be ordered so that $\lambda_1<\lambda_2<\lambda_3<\cdots$, with $\lambda_n\to\infty$ as $n\to\infty$. The different eigenfunctions $\varphi_n(x)$ and $\varphi_m(x)$ are orthogonal with weight $\rho(x)$ on the interval $x_1\le x\le x_2$; see formulas (M12.5.1.14).

Example. Consider the first boundary value problem in the domain $0 \le x \le l$ for the heat equation with a source

$$\frac{\partial w}{\partial t} = a\frac{\partial^2 w}{\partial x^2} - bw$$

under the initial condition (M12.7.1.3) and boundary conditions

$$w = g_1(t) \quad \text{at} \quad x = 0,$$
$$w = g_2(t) \quad \text{at} \quad x = l.$$

The above equation is a special case of equation (M12.7.2.1) with $\rho(x) = 1$, $p(x) = a$, $q(x) = b$, and $\Phi(x,t) = 0$. The corresponding Sturm–Liouville problem (M12.7.2.4) has the form

$$a\varphi''_{xx} + (\lambda - b)\varphi = 0, \qquad \varphi = 0 \quad \text{at} \quad x = 0, \qquad \varphi = 0 \quad \text{at} \quad x = l.$$

The eigenfunctions and eigenvalues are found to be

$$\varphi_n(x) = \sin\left(\frac{\pi n x}{l}\right), \qquad \lambda_n = b + \frac{a\pi^2 n^2}{l^2}, \qquad n = 1,\ 2,\ \dots$$

Using formula (M12.7.2.3) and taking into account that $\|\varphi_n\|^2 = l/2$, we obtain the Green's function

$$\mathcal{G}(x,y,t) = \frac{2}{l}e^{-bt}\sum_{n=1}^{\infty}\sin\left(\frac{\pi n x}{l}\right)\sin\left(\frac{\pi n y}{l}\right)\exp\left(-\frac{a\pi^2 n^2}{l^2}t\right).$$

Substituting this expression into (M12.7.2.2) with $p(x_1) = p(x_2) = \rho(y) = 1$, $x_1 = 0$, and $x_2 = l$ and taking into account the formulas

$$\Lambda_1(x,t) = \partial_y \mathcal{G}(x,y,t)\big|_{y=x_1}, \qquad \Lambda_2(x,t) = -\partial_y \mathcal{G}(x,y,t)\big|_{y=x_2}$$

(see the first row in Table M12.4 and Remark in Subsection M12.7.2), one obtains the solution to the problem in question.

M12.8. Boundary Value Problems for Hyperbolic Equations with One Space Variable. Green's Function. Goursat Problem

M12.8.1. Representation of Solutions in terms of the Green's Function

► **Statement of the problem ($t \ge 0,\ x_1 \le x \le x_2$).** In general, a one-dimensional nonhomogeneous linear differential equation of hyperbolic type with variable coefficients is written as

$$\frac{\partial^2 w}{\partial t^2} + \varphi(x,t)\frac{\partial w}{\partial t} - L_{x,t}[w] = \Phi(x,t), \qquad \text{(M12.8.1.1)}$$

where the operator $L_{x,t}[w]$ is defined by (M12.7.1.2).

Consider the nonstationary boundary value problem for equation (M12.8.1.1) with the initial conditions

$$\begin{aligned} w &= f_0(x) \quad \text{at} \quad t = 0,\\ \partial_t w &= f_1(x) \quad \text{at} \quad t = 0 \end{aligned} \qquad \text{(M12.8.1.2)}$$

and arbitrary nonhomogeneous linear boundary conditions (M12.7.1.4) and (M12.7.1.5).

► **Representation of the problem solution in terms of the Green's function.** The solution of problem (M12.8.1.1), (M12.8.1.2), (M12.7.1.4), (M12.7.1.5) can be represented as the sum

$$\begin{aligned} w(x,t) = & \int_0^t \int_{x_1}^{x_2} \Phi(y,\tau) G(x,y,t,\tau)\,dy\,d\tau \\ & - \int_{x_1}^{x_2} f_0(y) \left[\frac{\partial}{\partial\tau} G(x,y,t,\tau)\right]_{\tau=0} dy + \int_{x_1}^{x_2} \big[f_1(y) + f_0(y)\varphi(y,0)\big] G(x,y,t,0)\,dy \\ & + \int_0^t g_1(\tau) a(x_1,\tau) \Lambda_1(x,t,\tau)\,d\tau + \int_0^t g_2(\tau) a(x_2,\tau)\Lambda_2(x,t,\tau)\,d\tau. \end{aligned} \qquad \text{(M12.8.1.3)}$$

Here, the Green's function $G(x,y,t,\tau)$ is determined by solving the homogeneous equation

$$\frac{\partial^2 G}{\partial t^2} + \varphi(x,t)\frac{\partial G}{\partial t} - L_{x,t}[G] = 0 \qquad \text{(M12.8.1.4)}$$

with the semihomogeneous initial conditions

$$G = 0 \quad \text{at} \quad t = \tau, \qquad \text{(M12.8.1.5)}$$

$$\partial_t G = \delta(x-y) \quad \text{at} \quad t = \tau, \qquad \text{(M12.8.1.6)}$$

and the homogeneous boundary conditions (M12.7.1.9), (M12.7.1.10). The quantities y and τ appear in problem (M12.8.1.4)–(M12.8.1.6), (M12.7.1.9), (M12.7.1.10) as free parameters ($x_1 \le y \le x_2$), and $\delta(x)$ is the Dirac delta function.

The functions $\Lambda_1(x,t,\tau)$ and $\Lambda_2(x,t,\tau)$ involved in the integrands of the last two terms in solution (M12.8.1.3) can be expressed in terms of the Green's function $G(x,y,t,\tau)$. The corresponding formulas for $\Lambda_m(x,t,\tau)$ are given in Table M12.4 for the basic types of boundary value problems.

It is significant that the Green's function G and Λ_1, Λ_2 are independent of the functions Φ, f_0, f_1, g_1, and g_2 that characterize various nonhomogeneities of the boundary value problem.

If the coefficients of equation (M12.8.1.1) are independent of time t, then the Green's function depends on only three arguments, $G(x,y,t,\tau) = G(x,y,t-\tau)$. In this case, one can set $\frac{\partial}{\partial\tau} G(x,y,t,\tau)\big|_{\tau=0} = -\frac{\partial}{\partial t} G(x,y,t)$ in solution (M12.8.1.3).

► **Formulas for the calculation of Green's functions.** Consider the hyperbolic equation of a special form

$$\frac{\partial^2 w}{\partial t^2} + \beta(t)\frac{\partial w}{\partial t} = a(x)\frac{\partial^2 w}{\partial x^2} + b(x)\frac{\partial w}{\partial x} + \big[c(x) + \gamma(t)\big] w + \Phi(x,t), \qquad \text{(M12.8.1.7)}$$

which is a special case of equation (M12.8.1.1) with operator (M12.7.1.2) where $\varphi(x,t) = \beta(t)$, $a(x,t) = a(x)$, $b(x,t) = b(x)$, and $c(x,t) = c(x) + \gamma(t)$. We assume that $a(x) > 0$.

The solution of the nonhomogeneous linear boundary value problem (M12.8.1.7), (M12.8.1.2), (M12.7.1.4), (M12.7.1.5) is found by formula (M12.8.1.3), where the Green's function is given by

$$G(x,y,t,\tau) = \rho(y) \sum_{n=1}^{\infty} \frac{\varphi_n(x)\varphi_n(y)}{\|\varphi_n\|^2} \psi_n(t,\tau), \qquad \text{(M12.8.1.8)}$$

TABLE M12.6
The Green's functions for some boundary value problems for the wave equation $\frac{\partial^2 w}{\partial t^2} = a^2 \frac{\partial^2 w}{\partial x^2}$ in a bounded domain $0 \le x \le l$.

Type of problem	Green's function, $G(x,\xi,t)$	Remarks
First boundary value problem	$\dfrac{2}{a\pi}\sum_{n=1}^{\infty}\dfrac{1}{n}\sin\Bigl(\dfrac{n\pi x}{l}\Bigr)\sin\Bigl(\dfrac{n\pi\xi}{l}\Bigr)\sin\Bigl(\dfrac{n\pi at}{l}\Bigr)$	
Second boundary value problem	$\dfrac{t}{l}+\dfrac{2}{a\pi}\sum_{n=1}^{\infty}\dfrac{1}{n}\cos\Bigl(\dfrac{n\pi x}{l}\Bigr)\cos\Bigl(\dfrac{n\pi\xi}{l}\Bigr)\sin\Bigl(\dfrac{n\pi at}{l}\Bigr)$	
Mixed boundary value problem; w is set at $x=0$ and $\partial_x w$ is set at $x=l$	$\dfrac{2}{al}\sum_{n=1}^{\infty}\dfrac{1}{\lambda_n}\sin(\lambda_n x)\sin(\lambda_n\xi)\sin(\lambda_n at)$	$\lambda_n = \dfrac{\pi(2n+1)}{2l}$

where the λ_n and $\varphi_n(x)$ are the eigenvalues and the corresponding eigenfunctions of the Sturm–Liouville problem for the linear ordinary differential equation (M12.5.1.5) with the homogeneous linear boundary conditions (M12.5.1.7); $\rho(y)$ and $\|\varphi_n\|$ are determined by (M12.7.1.15), and $\psi = \psi_n(t,\tau)$ is the solution of equation (M12.5.2.5) with $\alpha(t) = 1$ and $\lambda = \lambda_n$ that satisfies the initial conditions

$$\psi = 0 \quad \text{at} \quad t = \tau, \qquad \psi'_t = 1 \quad \text{at} \quad t = \tau.$$

In the special case $\beta(t) = \gamma(t) = 0$, we have $\psi_n(t,\tau) = \lambda_n^{-1/2}\sin\bigl[\lambda_n^{1/2}(t-\tau)\bigr]$.

Table M12.6 lists Green's functions for some problems for a nonhomogeneous wave equation, which corresponds to $a(x,t) = a^2 = \text{const}$, $b(x) = c(x) = \beta(t) = \gamma(t) \equiv 0$ in (M12.8.1.7). One should substitute $G(x,y,t-\tau)$ from this table for $G(x,y,t,\tau)$ in formula (M12.8.1.3).

M12.8.2. Problems for Hyperbolic Equation $\rho(x)\frac{\partial^2 w}{\partial t^2} = \frac{\partial}{\partial x}\Bigl[p(x)\frac{\partial w}{\partial x}\Bigr] - q(x)w + \Phi(x,t)$

► **General relations for solving nonhomogeneous boundary value problems.** Consider a linear hyperbolic equation of the special form

$$\rho(x)\frac{\partial^2 w}{\partial t^2} = \frac{\partial}{\partial x}\biggl[p(x)\frac{\partial w}{\partial x}\biggr] - q(x)w + \Phi(x,t). \tag{M12.8.2.1}$$

It is assumed that the functions ρ, p, p'_x, and q are continuous and the inequalities $\rho > 0$, $p > 0$ hold for $x_1 \le x \le x_2$.

The solution of equation (M12.8.2.1) under the general initial conditions (M12.8.1.2) and the arbitrary linear nonhomogeneous boundary conditions (M12.7.1.4)–(M12.7.1.5) can be represented as the sum

$$\begin{aligned} w(x,t) &= \int_0^t\int_{x_1}^{x_2}\Phi(\xi,\tau)\mathcal{G}(x,\xi,t-\tau)\,d\xi\,d\tau \\ &\quad + \frac{\partial}{\partial t}\int_{x_1}^{x_2}\rho(\xi)f_0(\xi)\mathcal{G}(x,\xi,t)\,d\xi + \int_{x_1}^{x_2}\rho(\xi)f_1(\xi)\mathcal{G}(x,\xi,t)\,d\xi \\ &\quad + p(x_1)\int_0^t g_1(\tau)\Lambda_1(x,t-\tau)\,d\tau + p(x_2)\int_0^t g_2(\tau)\Lambda_2(x,t-\tau)\,d\tau. \end{aligned} \tag{M12.8.2.2}$$

Here, the modified Green's function is determined by

$$\mathcal{G}(x,\xi,t)=\sum_{n=1}^{\infty}\frac{\varphi_n(x)\varphi_n(\xi)\sin\bigl(t\sqrt{\lambda_n}\,\bigr)}{\|\varphi_n\|^2\sqrt{\lambda_n}},\qquad \|\varphi_n\|^2=\int_{x_1}^{x_2}\rho(x)\varphi_n^2(x)\,dx,\quad \text{(M12.8.2.3)}$$

where the λ_n and $\varphi_n(x)$ are the eigenvalues and the corresponding eigenfunctions of the Sturm–Liouville problem for the second-order linear ordinary differential equation:

$$\begin{gathered}[p(x)\varphi'_x]'_x+[\lambda\rho(x)-q(x)]\varphi=0,\\ s_1\varphi'_x+k_1\varphi=0\quad\text{at}\quad x=x_1,\\ s_2\varphi'_x+k_2\varphi=0\quad\text{at}\quad x=x_2.\end{gathered}\qquad \text{(M12.8.2.4)}$$

The functions $\Lambda_1(x,t)$ and $\Lambda_2(x,t)$ that occur in the integrands of the last two terms in solution (M12.8.2.2) are expressed in terms of the Green's function of (M12.8.2.3).

Remark. The corresponding formulas for $\Lambda_m(x,t)$ for the basic types of boundary value problems can be obtained using Table M12.4; to do so, one should set $G=\mathcal{G}$ in all formulas of the last column and omit the last argument τ.

► **Properties of the Sturm–Liouville problem. The Klein–Gordon equation.** The general and special properties of the Sturm–Liouville problem (M12.8.2.4) are given in Subsections M12.5.1 and M11.2.5; various asymptotic and approximate formulas for eigenvalues and eigenfunctions can also be found there.

Example. Consider the second boundary value problem in the domain $0\le x\le l$ for the Klein–Gordon equation

$$\frac{\partial^2 w}{\partial t^2}=a^2\frac{\partial^2 w}{\partial x^2}-bw,$$

under the initial conditions (M12.8.1.2) and boundary conditions

$$\begin{aligned}\partial_x w&=g_1(t)\quad\text{at}\quad x=0,\\ \partial_x w&=g_2(t)\quad\text{at}\quad x=l.\end{aligned}$$

The Klein–Gordon equation is a special case of equation (M12.8.2.1) with $\rho(x)=1$, $p(x)=a^2$, $q(x)=b$, and $\Phi(x,t)=0$. The corresponding Sturm–Liouville problem (M12.8.2.4) has the form

$$a^2\varphi''_{xx}+(\lambda-b)\varphi=0,\qquad \varphi'_x=0\quad\text{at}\quad x=0,\qquad \varphi'_x=0\quad\text{at}\quad x=l.$$

The eigenfunctions and eigenvalues are found to be

$$\varphi_{n+1}(x)=\cos\left(\frac{\pi nx}{l}\right),\qquad \lambda_{n+1}=b+\frac{a\pi^2n^2}{l^2},\qquad n=0,\ 1,\ \dots$$

Using formula (M12.8.2.3) and taking into account that $\|\varphi_1\|^2=l$ and $\|\varphi_n\|^2=l/2$ $(n=1,\ 2,\ \dots)$, we find the Green's function:

$$\mathcal{G}(x,\xi,t)=\frac{1}{l\sqrt{b}}\sin\bigl(t\sqrt{b}\,\bigr)+\frac{2}{l}\sum_{n=1}^{\infty}\cos\left(\frac{\pi nx}{l}\right)\cos\left(\frac{\pi n\xi}{l}\right)\frac{\sin\bigl(t\sqrt{(a\pi n/l)^2+b}\,\bigr)}{\sqrt{(a\pi n/l)^2+b}}.$$

Substituting this expression into (M12.8.2.2) with $p(x_1)=p(x_2)=\rho(\xi)=1$, $x_1=0$, and $x_2=l$ and taking into account the formulas

$$\Lambda_1(x,t)=-\mathcal{G}(x,x_1,t),\qquad \Lambda_2(x,t)=\mathcal{G}(x,x_2,t)$$

(see the second row in Table M12.4 and the above remark), one obtains the solution to the problem in question.

M12.8.3. Goursat Problem (a Problem with Initial Data of Characteristics)

► **Statement of the Goursat problem. Basic property of the solution.** Consider the general linear hyperbolic equation in two independent variables which is reduced to the first canonical form (see Subsection M12.2.1):

$$\frac{\partial^2 w}{\partial x \partial y} + a(x,y)\frac{\partial w}{\partial x} + b(x,y)\frac{\partial w}{\partial y} + c(x,y)w = f(x,y), \qquad \text{(M12.8.3.1)}$$

where $a(x,y)$, $b(x,y)$, $c(x,y)$, and $f(x,y)$ are continuous functions.

The *Goursat problem* for equation (M12.8.3.1) is stated as follows: find a solution to equation (M12.8.3.1) that satisfies the conditions at characteristics

$$w(x,y)|_{x=x_1} = g(y), \qquad w(x,y)|_{y=y_1} = h(x), \qquad \text{(M12.8.3.2)}$$

where $g(y)$ and $h(x)$ are given continuous functions that match each other at the point of intersection of the characteristics, so that

$$g(y_1) = h(x_1).$$

Basic properties of the Goursat problem: the value of the solution at any point $M(x_0,y_0)$ depends only on the values of $g(y)$ at the segment AN (which is part of the characteristic $x = x_1$), the values of $h(x)$ at the segment BN (which is part of the characteristic $y = y_1$), and the values of the functions $a(x,y)$, $b(x,y)$, $c(x,y)$, and $f(x,y)$ in the rectangle $NAMB$; see Fig. M12.2. The domain of influence on the solution at the point $M(x_0,y_0)$ is shaded for clarity.

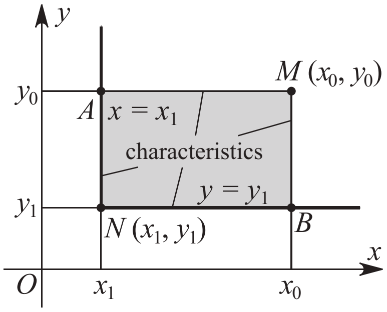


Figure M12.2. Domain of influence of the solution to the Goursat problem at a point M.

► **Riemann function.** A *Riemann function*, $\mathcal{R} = \mathcal{R}(x,y;x_0,y_0)$, corresponding to equation (M12.8.3.1) is defined as a solution to the equation

$$\frac{\partial^2 \mathcal{R}}{\partial x \partial y} - \frac{\partial}{\partial x}\Big[a(x,y)\mathcal{R}\Big] - \frac{\partial}{\partial y}\Big[b(x,y)\mathcal{R}\Big] + c(x,y)\mathcal{R} = 0 \qquad \text{(M12.8.3.3)}$$

that satisfies the conditions

$$\mathcal{R} = \exp\left[\int_{y_0}^{y} a(x_0,\xi)\,d\xi\right] \quad \text{at} \quad x = x_0, \qquad \mathcal{R} = \exp\left[\int_{x_0}^{x} b(\xi,y_0)\,d\xi\right] \quad \text{at} \quad y = y_0 \qquad \text{(M12.8.3.4)}$$

at the characteristics $x = x_0$ and $y = y_0$. Here, (x_0,y_0) is an arbitrary point from the domain of definition of equation (M12.8.3.1). The x_0 and y_0 appear in problem (M12.8.3.3), (M12.8.3.4) as parameters in the boundary conditions only.

THEOREM. *If the functions a, b, c and the partial derivatives a_x, b_y are all continuous, then the Riemann function $\mathcal{R}(x,y;x_0,y_0)$ exists. Moreover, the function $\mathcal{R}(x_0,y_0,x,y)$, obtained by swapping the parameters and the arguments, is a solution to the homogeneous equation (M12.8.3.1), with $f=0$.*

Remark. It is significant that the Riemann function is independent of the initial data on characteristics (M12.8.3.2).

Example 1. The Riemann function for the equation $w_{xy}=0$ is just $\mathcal{R}\equiv 1$.

Example 2. The Riemann function for the equation

$$w_{xy}+cw=0 \qquad (c=\text{const})$$

is expressed in terms of the Bessel function $J_0(z)$ as

$$\mathcal{R}=J_0\bigl(\sqrt{4c(x_0-x)(y_0-y)}\,\bigr).$$

► **Solution representation for the Goursat problem in terms of the Riemann function.** Given a Riemann function, the solution to the Goursat problem (M12.8.3.1), (M12.8.3.2) at any point (x_0,y_0) can be written as

$$w(x_0,y_0)=(w\mathcal{R})_N+\int_N^A \mathcal{R}\bigl(g'_y+bg\bigr)\,dy+\int_N^B \mathcal{R}\bigl(h'_x+ah\bigr)\,dx+\iint_{NAMB} f\mathcal{R}\,dx\,dy.$$

The first term on the right-hand side is evaluated at the point of intersection of the characteristics (x_1,y_1). The second and third terms are integrals along the characteristics $y=y_1$ $(x_1\le x\le x_0)$ and $x=x_1$ $(y_1\le y\le y_0)$; these involve the initial data of (M12.8.3.2). The last integral is taken over the rectangular domain $NAMB$ defined by the inequalities $x_1\le x\le x_0$, $y_1\le y\le y_0$.

The Goursat problem for a hyperbolic equation reduced to the second canonical form (see Subsection M12.2.1) is treated similarly.

Example 3. Consider the Goursat problem for the wave equation

$$\frac{\partial^2 w}{\partial t^2}-a^2\frac{\partial^2 w}{\partial x^2}=0$$

with the boundary conditions prescribed on its characteristics

$$\begin{aligned} w&=f(x) \quad \text{for} \quad x-at=0 \quad (0\le x\le b),\\ w&=g(x) \quad \text{for} \quad x+at=0 \quad (0\le x\le c), \end{aligned} \qquad \text{(M12.8.3.5)}$$

where $f(0)=g(0)$.

Substituting the values set on the characteristics (M12.8.3.5) into the general solution of the wave equation, $w=\varphi(x-at)+\psi(x+at)$, we arrive to a system of linear algebraic equations for $\varphi(x)$ and $\psi(x)$. As a result, the solution to the Goursat problem is obtained in the form

$$w(x,t)=f\left(\frac{x+at}{2}\right)+g\left(\frac{x-at}{2}\right)-f(0).$$

The propagation domain of the solution is the parallelogram bounded by the four straight lines

$$x-at=0, \quad x+at=0, \quad x-at=2c, \quad x+at=2b.$$

M12.9. Boundary Value Problems for Elliptic Equations with Two Space Variables

M12.9.1. Problems and the Green's Functions for Equation $a(x)\dfrac{\partial^2 w}{\partial x^2}+\dfrac{\partial^2 w}{\partial y^2}+b(x)\dfrac{\partial w}{\partial x}+c(x)w=-\Phi(x,y)$

► **Statements of boundary value problems.** Consider two-dimensional boundary value problems for the equation

$$a(x)\frac{\partial^2 w}{\partial x^2}+\frac{\partial^2 w}{\partial y^2}+b(x)\frac{\partial w}{\partial x}+c(x)w=-\Phi(x,y) \qquad \text{(M12.9.1.1)}$$

with general boundary conditions in x,

$$\begin{aligned} s_1\frac{\partial w}{\partial x}-k_1w&=f_1(y) \quad \text{at} \quad x=x_1,\\ s_2\frac{\partial w}{\partial x}+k_2w&=f_2(y) \quad \text{at} \quad x=x_2, \end{aligned} \qquad \text{(M12.9.1.2)}$$

and different boundary conditions in y. It is assumed that the coefficients of equation (M12.9.1.1) and the boundary conditions (M12.9.1.2) meet the requirements

$$a(x),\ b(x),\ c(x) \text{ are continuous } (x_1\le x\le x_2); \quad a>0, \quad |s_1|+|k_1|>0, \quad |s_2|+|k_2|>0.$$

► **Relations for the Green's function.** In the general case, the Green's function can be represented as

$$G(x,y,\xi,\eta)=\rho(\xi)\sum_{n=1}^{\infty}\frac{\varphi_n(x)\varphi_n(\xi)}{\|\varphi_n\|^2}\Psi_n(y,\eta;\lambda_n), \qquad \text{(M12.9.1.3)}$$

where

$$\rho(x)=\frac{1}{a(x)}\exp\left[\int\frac{b(x)}{a(x)}\,dx\right], \quad \|\varphi_n\|^2=\int_{x_1}^{x_2}\rho(x)\varphi_n^2(x)\,dx, \qquad \text{(M12.9.1.4)}$$

and the λ_n and $\varphi_n(x)$ are the eigenvalues and eigenfunctions of the homogeneous boundary value problem for the ordinary differential equation

$$a(x)\varphi''_{xx}+b(x)\varphi'_x+[\lambda+c(x)]\varphi=0, \qquad \text{(M12.9.1.5)}$$

$$s_1\varphi'_x-k_1\varphi=0 \quad \text{at} \quad x=x_1, \qquad \text{(M12.9.1.6)}$$

$$s_2\varphi'_x+k_2\varphi=0 \quad \text{at} \quad x=x_2. \qquad \text{(M12.9.1.7)}$$

The functions Ψ_n for various boundary conditions in y are specified in Table M12.7.

Example. Consider a boundary value problem for the Laplace equation

$$\frac{\partial^2 w}{\partial x^2}+\frac{\partial^2 w}{\partial y^2}=0 \qquad \text{(M12.9.1.8)}$$

in a strip $0\le x\le l$, $-\infty<y<\infty$ with mixed boundary conditions

$$w=f_1(y) \quad \text{at} \quad x=0, \qquad \frac{\partial w}{\partial x}=f_2(y) \quad \text{at} \quad x=l.$$

TABLE M12.7

The functions Ψ_n in (M12.9.1.3) for various boundary conditions. Notation: $\sigma_n = \sqrt{\lambda_n}$.

Domain	Boundary conditions	Function $\Psi_n(y, \eta; \lambda_n)$
$-\infty < y < \infty$	$\lvert w\rvert < \infty$ for $y \to \pm\infty$	$\frac{1}{2\sigma_n} e^{-\sigma_n \lvert y-\eta\rvert}$
$0 \le y < \infty$	$w = 0$ for $y = 0$	$\frac{1}{\sigma_n}\begin{cases} e^{-\sigma_n y}\sinh(\sigma_n\eta) & \text{for } y > \eta, \\ e^{-\sigma_n \eta}\sinh(\sigma_n y) & \text{for } \eta > y \end{cases}$
$0 \le y < \infty$	$\partial_y w = 0$ for $y = 0$	$\frac{1}{\sigma_n}\begin{cases} e^{-\sigma_n y}\cosh(\sigma_n\eta) & \text{for } y > \eta, \\ e^{-\sigma_n \eta}\cosh(\sigma_n y) & \text{for } \eta > y \end{cases}$
$0 \le y < \infty$	$\partial_y w - k_3 w = 0$ for $y = 0$	$\frac{1}{\sigma_n(\sigma_n + k_3)}\begin{cases} e^{-\sigma_n y}[\sigma_n\cosh(\sigma_n\eta) + k_3\sinh(\sigma_n\eta)] & \text{for } y > \eta, \\ e^{-\sigma_n \eta}[\sigma_n\cosh(\sigma_n y) + k_3\sinh(\sigma_n y)] & \text{for } \eta > y \end{cases}$
$0 \le y \le h$	$w = 0$ at $y = 0$, $w = 0$ at $y = h$	$\frac{1}{\sigma_n \sinh(\sigma_n h)}\begin{cases} \sinh(\sigma_n\eta)\sinh[\sigma_n(h-y)] & \text{for } y > \eta, \\ \sinh(\sigma_n y)\sinh[\sigma_n(h-\eta)] & \text{for } \eta > y \end{cases}$
$0 \le y \le h$	$\partial_y w = 0$ at $y = 0$, $\partial_y w = 0$ at $y = h$	$\frac{1}{\sigma_n \sinh(\sigma_n h)}\begin{cases} \cosh(\sigma_n\eta)\cosh[\sigma_n(h-y)] & \text{for } y > \eta, \\ \cosh(\sigma_n y)\cosh[\sigma_n(h-\eta)] & \text{for } \eta > y \end{cases}$
$0 \le y \le h$	$w = 0$ at $y = 0$, $\partial_y w = 0$ at $y = h$	$\frac{1}{\sigma_n \cosh(\sigma_n h)}\begin{cases} \sinh(\sigma_n\eta)\cosh[\sigma_n(h-y)] & \text{for } y > \eta, \\ \sinh(\sigma_n y)\cosh[\sigma_n(h-\eta)] & \text{for } \eta > y \end{cases}$

This equation is a special case of equation (M12.9.1.1) with $a(x) = 1$ and $b(x) = c(x) = \Phi(x,t) = 0$. The corresponding Sturm–Liouville problem (M12.9.1.5)–(M12.9.1.7) is written as

$$u''_{xx} + \lambda u = 0, \qquad u = 0 \quad \text{at} \quad x = 0, \qquad u'_x = 0 \quad \text{at} \quad x = l.$$

The eigenfunctions and eigenvalues are found as

$$\varphi_n(x) = \sin\left[\frac{\pi(2n-1)x}{l}\right], \qquad \lambda_n = \frac{\pi^2(2n-1)^2}{l^2}, \qquad n = 1,\ 2,\ \ldots$$

Using formulas (M12.9.1.3) and (M12.9.1.4) and taking into account the identities $\rho(\xi) = 1$ and $\|y_n\|^2 = l/2$ ($n = 1,\ 2,\ \ldots$) and the expression for Ψ_n from the first row in Table M12.7, we obtain the Green's function in the form

$$G(x,y,\xi,\eta) = \frac{1}{l}\sum_{n=1}^{\infty}\frac{1}{\sigma_n}\sin(\sigma_n x)\sin(\sigma_n \xi)e^{-\sigma_n|y-\eta|}, \qquad \sigma_n = \sqrt{\lambda_n} = \frac{\pi(2n-1)}{l}.$$

M12.9.2. Representation of Solutions to Boundary Value Problems via the Green's Functions

► **First boundary value problem.** The solution of the first boundary value problem for equation (M12.9.1.1) with the boundary conditions

$$w = f_1(y) \quad \text{at} \quad x = x_1, \qquad w = f_2(y) \quad \text{at} \quad x = x_2,$$
$$w = f_3(x) \quad \text{at} \quad y = 0, \qquad w = f_4(x) \quad \text{at} \quad y = h$$

is expressed in terms of the Green's function as

$$\begin{aligned} w(x,y) = {}& a(x_1)\int_0^h f_1(\eta)\left[\frac{\partial}{\partial\xi}G(x,y,\xi,\eta)\right]_{\xi=x_1} d\eta - a(x_2)\int_0^h f_2(\eta)\left[\frac{\partial}{\partial\xi}G(x,y,\xi,\eta)\right]_{\xi=x_2} d\eta \\ &+ \int_{x_1}^{x_2} f_3(\xi)\left[\frac{\partial}{\partial\eta}G(x,y,\xi,\eta)\right]_{\eta=0} d\xi - \int_{x_1}^{x_2} f_4(\xi)\left[\frac{\partial}{\partial\eta}G(x,y,\xi,\eta)\right]_{\eta=h} d\xi \\ &+ \int_{x_1}^{x_2}\int_0^h \Phi(\xi,\eta)G(x,y,\xi,\eta)\,d\eta\,d\xi. \end{aligned}$$

► **Second boundary value problem.** The solution of the second boundary value problem for equation (M12.9.1.1) with the boundary conditions

$$\begin{aligned} &\partial_x w = f_1(y) \quad \text{at} \quad x = x_1, \qquad \partial_x w = f_2(y) \quad \text{at} \quad x = x_2, \\ &\partial_y w = f_3(x) \quad \text{at} \quad y = 0, \qquad \partial_y w = f_4(x) \quad \text{at} \quad y = h \end{aligned}$$

is expressed in terms of the Green's function as

$$\begin{aligned} w(x,y) = &-a(x_1)\int_0^h f_1(\eta)G(x,y,x_1,\eta)\,d\eta + a(x_2)\int_0^h f_2(\eta)G(x,y,x_2,\eta)\,d\eta \\ &-\int_{x_1}^{x_2} f_3(\xi)G(x,y,\xi,0)\,d\xi + \int_{x_1}^{x_2} f_4(\xi)G(x,y,\xi,h)\,d\xi \\ &+\int_{x_1}^{x_2}\int_0^h \Phi(\xi,\eta)G(x,y,\xi,\eta)\,d\eta\,d\xi. \end{aligned}$$

M12.9.3. Solutions of Problems for the Laplace Equation in the Polar Coordinate System

In the polar coordinates, defined by $x = r\cos\varphi$ and $y = r\sin\varphi$, Laplace's equation (M12.9.1.8) becomes

$$\Delta w \equiv \frac{1}{r}\frac{\partial}{\partial r}\left(r\frac{\partial w}{\partial r}\right) + \frac{1}{r^2}\frac{\partial^2 w}{\partial \varphi^2} = 0. \qquad \text{(M12.9.3.1)}$$

► **First boundary value problem ($0 \le r \le R$).** A circle is considered. A boundary condition is prescribed:

$$w = f(\varphi) \quad \text{at} \quad r = R. \qquad \text{(M12.9.3.2)}$$

The solution to equation (M12.9.3.1) subject to the boundary condition (M12.9.3.2) is given by

$$w(r,\varphi) = \frac{1}{2\pi}\int_0^{2\pi} f(\psi)\frac{R^2 - r^2}{r^2 - 2Rr\cos(\varphi - \psi) + R^2}\,d\psi.$$

This formula is conventionally referred to as the *Poisson integral*.

► **Second boundary value problem ($0 \le r \le R$).** A circle is considered. A boundary condition is prescribed:

$$\partial_r w = f(\varphi) \quad \text{at} \quad r = R. \qquad \text{(M12.9.3.3)}$$

The solution to equation (M12.9.3.1) subject to the boundary condition (M12.9.3.3) is expressed as

$$w(r,\varphi) = \frac{R}{2\pi}\int_0^{2\pi} f(\psi)\ln\frac{r^2 - 2Rr\cos(\varphi - \psi) + R^2}{R^2}\,d\psi + C,$$

where C is an arbitrary constant; this formula is known as the *Dini integral*.

Remark. The function $f(\varphi)$ must satisfy the solvability condition $\int_0^{2\pi} f(\varphi)\,d\varphi = 0$.

M12.10. Problems with Many Space Variables. Representation of Solutions via Green's Functions

M12.10.1. Boundary Value Problems for Parabolic Equations

► **Statement of the problem.** In general, a nonhomogeneous linear differential equation of the parabolic type in n space variables has the form

$$\frac{\partial w}{\partial t} - L_{\mathbf{x},t}[w] = \Phi(\mathbf{x},t), \qquad \text{(M12.10.1.1)}$$

where

$$\begin{gathered} L_{\mathbf{x},t}[w] \equiv \sum_{i,j=1}^{n} a_{ij}(\mathbf{x},t)\frac{\partial^2 w}{\partial x_i \partial x_j} + \sum_{i=1}^{n} b_i(\mathbf{x},t)\frac{\partial w}{\partial x_i} + c(\mathbf{x},t)w, \\ \mathbf{x} = \{x_1,\dots,x_n\}, \quad \sum_{i,j=1}^{n} a_{ij}(\mathbf{x},t)\xi_i\xi_j \ge \sigma \sum_{i=1}^{n}\xi_i^2, \quad \sigma > 0. \end{gathered} \qquad \text{(M12.10.1.2)}$$

Let V be some simply connected domain in $\mathbb{R}^n$ with a sufficiently smooth boundary S. We consider the nonstationary boundary value problem for equation (M12.10.1.1) in the domain V with an arbitrary initial condition,

$$w = f(\mathbf{x}) \quad \text{at} \quad t = 0, \qquad \text{(M12.10.1.3)}$$

and nonhomogeneous linear boundary conditions,

$$\Gamma_{\mathbf{x},t}[w] = g(\mathbf{x},t) \quad \text{for} \quad \mathbf{x} \in S. \qquad \text{(M12.10.1.4)}$$

In the general case, $\Gamma_{\mathbf{x},t}$ is a first-order linear differential operator in the space coordinates with coefficients dependent on $\mathbf{x}$ and t.

► **Representation of the problem solution in terms of the Green's function.** The solution of the nonhomogeneous linear boundary value problem defined by (M12.10.1.1)–(M12.10.1.4) can be represented as the sum

$$\begin{aligned} w(\mathbf{x},t) = {} & \int_0^t \int_V \Phi(\mathbf{y},\tau) G(\mathbf{x},\mathbf{y},t,\tau)\, dV_y\, d\tau + \int_V f(\mathbf{y}) G(\mathbf{x},\mathbf{y},t,0)\, dV_y \\ & + \int_0^t \int_S g(\mathbf{y},\tau) H(\mathbf{x},\mathbf{y},t,\tau)\, dS_y\, d\tau, \end{aligned} \qquad \text{(M12.10.1.5)}$$

where $G(\mathbf{x},\mathbf{y},t,\tau)$ is the Green's function; for $t > \tau \ge 0$, it satisfies the homogeneous equation

$$\frac{\partial G}{\partial t} - L_{\mathbf{x},t}[G] = 0 \qquad \text{(M12.10.1.6)}$$

with the nonhomogeneous initial condition of special form

$$G = \delta(\mathbf{x}-\mathbf{y}) \quad \text{at} \quad t = \tau \qquad \text{(M12.10.1.7)}$$

and the homogeneous boundary condition

$$\Gamma_{\mathbf{x},t}[G]=0 \quad \text{for} \quad \mathbf{x}\in S. \qquad \text{(M12.10.1.8)}$$

The vector $\mathbf{y}=\{y_1,\dots,y_n\}$ appears in problem (M12.10.1.6)–(M12.10.1.8) as an n-dimensional free parameter ($\mathbf{y}\in V$), and $\delta(\mathbf{x}-\mathbf{y})=\delta(x_1-y_1)\dots\delta(x_n-y_n)$ is the n-dimensional Dirac delta function. The Green's function G is independent of the functions Φ, f, and g that characterize various nonhomogeneities of the boundary value problem. In (M12.10.1.5), the integration is performed everywhere with respect to $\mathbf{y}$, with $dV_y=dy_1\dots dy_n$.

The function $H(\mathbf{x},\mathbf{y},t,\tau)$ in the integrand of the last term in solution (M12.10.1.5) can be expressed via the Green's function $G(\mathbf{x},\mathbf{y},t,\tau)$. The corresponding formulas for $H(\mathbf{x},\mathbf{y},t,\tau)$ are given in Table M12.8 for the three basic types of boundary value problems; in the third boundary value problem, the coefficient k can depend on $\mathbf{x}$ and t. The boundary conditions of the second and third kinds, as well as the solution of the first boundary value problem, involve operators of differentiation along the conormal of operator (M12.10.1.2); these operators act as follows:

$$\frac{\partial G}{\partial M_x}\equiv\sum_{i,j=1}^{n}a_{ij}(\mathbf{x},t)N_j\frac{\partial G}{\partial x_i},\qquad \frac{\partial G}{\partial M_y}\equiv\sum_{i,j=1}^{n}a_{ij}(\mathbf{y},\tau)N_j\frac{\partial G}{\partial y_i}, \qquad \text{(M12.10.1.9)}$$

where $\mathbf{N}=\{N_1,\dots,N_n\}$ is the unit outward normal to the surface S. In the special case where $a_{ii}(\mathbf{x},t)=1$ and $a_{ij}(\mathbf{x},t)=0$ for $i\neq j$, operator (M12.10.1.9) coincides with the ordinary operator of differentiation along the outward normal to S.

TABLE M12.8
The form of the function $H(\mathbf{x},\mathbf{y},t,\tau)$ for the basic types of nonstationary boundary value problems.

Type of problem	Form of boundary condition (M12.10.1.4)	Function $H(\mathbf{x},\mathbf{y},t,\tau)$
First boundary value problem	$w=g(\mathbf{x},t)$ for $\mathbf{x}\in S$	$H(\mathbf{x},\mathbf{y},t,\tau)=-\frac{\partial G}{\partial M_y}(\mathbf{x},\mathbf{y},t,\tau)$
Second boundary value problem	$\frac{\partial w}{\partial M_x}=g(\mathbf{x},t)$ for $\mathbf{x}\in S$	$H(\mathbf{x},\mathbf{y},t,\tau)=G(\mathbf{x},\mathbf{y},t,\tau)$
Third boundary value problem	$\frac{\partial w}{\partial M_x}+kw=g(\mathbf{x},t)$ for $\mathbf{x}\in S$	$H(\mathbf{x},\mathbf{y},t,\tau)=G(\mathbf{x},\mathbf{y},t,\tau)$

If the coefficient of equation (M12.10.1.6) and the boundary condition (M12.10.1.8) are independent of t, then the Green's function depends on only three arguments, $G(\mathbf{x},\mathbf{y},t,\tau)=G(\mathbf{x},\mathbf{y},t-\tau)$.

Remark. Let S_i ($i=1,\dots,p$) be different portions of the surface S such that $S=\sum_{i=1}^{p}S_i$ and let boundary conditions of various types be set on the S_i,

$$\Gamma^{(i)}_{\mathbf{x},t}[w]=g_i(\mathbf{x},t) \quad \text{for} \quad \mathbf{x}\in S_i, \qquad i=1,\dots,p. \qquad \text{(M12.10.1.10)}$$

Then formula (M12.10.1.5) remains valid but the last term in (M12.10.1.5) must be replaced by the sum

$$\sum_{i=1}^{p}\int_0^t\int_{S_i}g_i(\mathbf{y},\tau)H_i(\mathbf{x},\mathbf{y},t,\tau)\,dS_y\,d\tau. \qquad \text{(M12.10.1.11)}$$

M12.10.2. Boundary Value Problems for Hyperbolic Equations

► **Statement of the problem.** The general nonhomogeneous linear differential hyperbolic equation in n space variables can be written as

$$\frac{\partial^2 w}{\partial t^2} + \varphi(\mathbf{x},t)\frac{\partial w}{\partial t} - L_{\mathbf{x},t}[w] = \Phi(\mathbf{x},t), \qquad \text{(M12.10.2.1)}$$

where the operator $L_{\mathbf{x},t}[w]$ is defined explicitly in (M12.10.1.2).

We consider the nonstationary boundary value problem for equation (M12.10.2.1) in the domain V with arbitrary initial conditions,

$$w = f_0(\mathbf{x}) \quad \text{at} \quad t=0, \qquad \text{(M12.10.2.2)}$$

$$\partial_t w = f_1(\mathbf{x}) \quad \text{at} \quad t=0, \qquad \text{(M12.10.2.3)}$$

and the nonhomogeneous linear boundary condition (M12.10.1.4).

► **Representation of the problem solution in terms of the Green's function.** The solution of the nonhomogeneous linear boundary value problem defined by (M12.10.2.1)–(M12.10.2.3), (M12.10.1.4) can be represented as the sum

$$\begin{aligned} w(\mathbf{x},t) &= \int_0^t \int_V \Phi(\mathbf{y},\tau) G(\mathbf{x},\mathbf{y},t,\tau)\, dV_y\, d\tau - \int_V f_0(\mathbf{y}) \left[\frac{\partial}{\partial \tau} G(\mathbf{x},\mathbf{y},t,\tau)\right]_{\tau=0} dV_y \\ &+ \int_V \bigl[f_1(\mathbf{y}) + f_0(\mathbf{y})\varphi(\mathbf{y},0)\bigr] G(\mathbf{x},\mathbf{y},t,0)\, dV_y \\ &+ \int_0^t \int_S g(\mathbf{y},\tau) H(\mathbf{x},\mathbf{y},t,\tau)\, dS_y\, d\tau. \end{aligned} \qquad \text{(M12.10.2.4)}$$

Here, $G(\mathbf{x},\mathbf{y},t,\tau)$ is the Green's function; for $t > \tau \geq 0$, it satisfies the homogeneous equation

$$\frac{\partial^2 G}{\partial t^2} + \varphi(\mathbf{x},t)\frac{\partial G}{\partial t} - L_{\mathbf{x},t}[G] = 0 \qquad \text{(M12.10.2.5)}$$

with the semihomogeneous initial conditions

$$\begin{aligned} G &= 0 && \text{at} \quad t=\tau, \\ \partial_t G &= \delta(\mathbf{x}-\mathbf{y}) && \text{at} \quad t=\tau, \end{aligned}$$

and the homogeneous boundary condition (M12.10.1.8).

If the coefficients of equation (M12.10.2.5) and the boundary condition (M12.10.1.8) are independent of time t, then the Green's function depends on only three arguments, $G(\mathbf{x},\mathbf{y},t,\tau) = G(\mathbf{x},\mathbf{y},t-\tau)$. In this case, one can set $\frac{\partial}{\partial\tau} G(\mathbf{x},\mathbf{y},t,\tau)\big|_{\tau=0} = -\frac{\partial}{\partial t} G(\mathbf{x},\mathbf{y},t)$ in solution (M12.10.2.4).

The function $H(\mathbf{x},\mathbf{y},t,\tau)$ in the integrand of the last term in solution (M12.10.2.4) can be expressed via the Green's function $G(\mathbf{x},\mathbf{y},t,\tau)$. The corresponding formulas for H are given in Table M12.8 for the three basic types of boundary value problems; in the third boundary value problem, the coefficient k can depend on $\mathbf{x}$ and t.

M12.10.3. Boundary Value Problems for Elliptic Equations

► **Statement of the problem.** In general, a nonhomogeneous linear elliptic equation can be written as

$$-L_{\mathbf{x}}[w]=\Phi(\mathbf{x}),\qquad\text{(M12.10.3.1)}$$

where

$$L_{\mathbf{x}}[w]\equiv\sum_{i,j=1}^{n}a_{ij}(\mathbf{x})\frac{\partial^2 w}{\partial x_i\partial x_j}+\sum_{i=1}^{n}b_i(\mathbf{x})\frac{\partial w}{\partial x_i}+c(\mathbf{x})w.\qquad\text{(M12.10.3.2)}$$

We consider equation (M12.10.3.1) with operator (M12.10.3.2) in a domain V and assume that the equation is subject to the general linear boundary condition

$$\Gamma_{\mathbf{x}}[w]=g(\mathbf{x})\quad\text{for}\quad\mathbf{x}\in S.\qquad\text{(M12.10.3.3)}$$

The solution of the stationary problem (M12.10.3.1)–(M12.10.3.3) can be obtained by passing in (M12.10.1.5) to the limit as $t\to\infty$. To this end, one should start with equation (M12.10.1.1), whose coefficients are independent of t, and take the homogeneous initial condition (M12.10.1.3), with $f(\mathbf{x})=0$, and the stationary boundary condition (M12.10.3.3).

► **Representation of the problem solution in terms of the Green's function.** The solution of the linear boundary value problem (M12.10.3.1)–(M12.10.3.3) can be represented as the sum

$$w(\mathbf{x})=\int_V\Phi(\mathbf{y})G(\mathbf{x},\mathbf{y})\,dV_y+\int_S g(\mathbf{y})H(\mathbf{x},\mathbf{y})\,dS_y.\qquad\text{(M12.10.3.4)}$$

Here, the Green's function $G(\mathbf{x},\mathbf{y})$ satisfies the nonhomogeneous equation of special form

$$-L_{\mathbf{x}}[G]=\delta(\mathbf{x}-\mathbf{y})\qquad\text{(M12.10.3.5)}$$

with the homogeneous boundary condition

$$\Gamma_{\mathbf{x}}[G]=0\quad\text{for}\quad\mathbf{x}\in S.\qquad\text{(M12.10.3.6)}$$

The vector $\mathbf{y}=\{y_1,\dots,y_n\}$ appears in problem (M12.10.3.5), (M12.10.3.6) as an n-dimensional free parameter ($\mathbf{y}\in V$). Note that G is independent of the functions Φ and g characterizing various nonhomogeneities of the original boundary value problem.

The function $H(\mathbf{x},\mathbf{y})$ in the integrand of the second term in solution (M12.10.3.4) can be expressed via the Green's function $G(\mathbf{x},\mathbf{y})$. The corresponding formulas for H for the three basic types of boundary value problems can be obtained using Table M12.8, where one should consider the functions to be independent of t and τ. The boundary conditions of the second and third kinds, as well as the solution of the first boundary value problem, involve operators of differentiation along the conormal of operator (M12.10.3.2); these operators are defined by (M12.10.1.9); in this case, the coefficients a_{ij} depend on $\mathbf{x}$ only.

M12.10.4. Construction of the Green's Functions. General Formulas and Relations

Table M12.9 lists the Green's functions of boundary value problems for second-order equations of various types in a bounded domain V. It is assumed that $L_{\mathbf{x}}$ is a second-order linear (self-adjoint) differential operator of the form

$$L_{\mathbf{x}}[w]\equiv\sum_{i,j=1}^{n}\frac{\partial}{\partial x_i}\left[a_{ij}(\mathbf{x})\frac{\partial w}{\partial x_j}\right],\quad\text{where}\quad\sum_{i,j=1}^{n}a_{ij}(\mathbf{x})\xi_i\xi_j\ge\sigma\sum_{i=1}^{n}\xi_i^2,\quad\sigma>0,$$

TABLE M12.9
The Green's functions of boundary value problems for equations of various types in bounded domains. In all problems, the operators $L_{\mathbf{x}}$ and $\Gamma_{\mathbf{x}}$ are the same; $\mathbf{x} = \{x_1, \dots, x_n\}$.

Equation	Initial and boundary conditions	Green's function
Elliptic equation $-L_{\mathbf{x}}[w] = \Phi(\mathbf{x})$	$\Gamma_{\mathbf{x}}[w] = g(\mathbf{x})$ for $\mathbf{x} \in S$ (no initial condition required)	$G(\mathbf{x},\mathbf{y}) = \sum\limits_{k=1}^{\infty} \dfrac{u_k(\mathbf{x})u_k(\mathbf{y})}{\lVert u_k \rVert^2 \lambda_k}, \quad \lambda_k \neq 0$
Parabolic equation $\partial_t w - L_{\mathbf{x}}[w] = \Phi(\mathbf{x},t)$	$w = f(\mathbf{x})$ at $t = 0$ $\Gamma_{\mathbf{x}}[w] = g(\mathbf{x},t)$ for $\mathbf{x} \in S$	$G(\mathbf{x},\mathbf{y},t) = \sum\limits_{k=1}^{\infty} \dfrac{u_k(\mathbf{x})u_k(\mathbf{y})}{\lVert u_k \rVert^2} \exp(-\lambda_k t)$
Hyperbolic equation $\partial_{tt} w - L_{\mathbf{x}}[w] = \Phi(\mathbf{x},t)$	$w = f_0(\mathbf{x})$ at $t = 0$ $w = f_1(\mathbf{x})$ at $t = 0$ $\Gamma_{\mathbf{x}}[w] = g(\mathbf{x},t)$ for $\mathbf{x} \in S$	$G(\mathbf{x},\mathbf{y},t) = \sum\limits_{k=1}^{\infty} \dfrac{u_k(\mathbf{x})u_k(\mathbf{y})}{\lVert u_k \rVert^2 \sqrt{\lambda_k}} \sin\bigl(t\sqrt{\lambda_k}\bigr)$

in the space variables $x_1, \dots, x_n$, and $\Gamma_{\mathbf{x}}$ is a zeroth- or first-order linear boundary operator that can define a boundary condition of the first, second, or third kind; the coefficients of the operators $L_{\mathbf{x}}$ and $\Gamma_{\mathbf{x}}$ can depend on the space variables but are independent of time t. The coefficients λ_k and the functions $u_k(\mathbf{x})$ are determined by solving the homogeneous eigenvalue problem

$$L_{\mathbf{x}}[u] + \lambda u = 0, \qquad \text{(M12.11.1.1)}$$

$$\Gamma_{\mathbf{x}}[u] = 0 \quad \text{for} \quad \mathbf{x} \in S. \qquad \text{(M12.11.1.2)}$$

It is apparent from Table M12.9 that, given the Green's function in the problem for a parabolic (or hyperbolic) equation, one can easily construct the Green's functions of the corresponding problems for elliptic and hyperbolic (or parabolic) equations. In particular, the Green's function of the problem for an elliptic equation can be expressed via the Green's function of the problem for a parabolic equation as follows:

$$G_0(\mathbf{x},\mathbf{y}) = \int_0^{\infty} G_1(\mathbf{x},\mathbf{y},t)\,dt. \qquad \text{(M12.11.1.3)}$$

It is assumed here that $\lambda = 0$ is not an eigenvalue of problem (M12.11.1.1), (M12.11.1.2).

Remark 1. Formula (M12.11.1.3) can also be used if the domain V is infinite. In this case, one should make sure that the integral on the right-hand side is convergent.

Remark 2. Suppose the equations given in the first column of Table M12.9 contain $-L_{\mathbf{x}}[w] - \beta w$ instead of $-L_{\mathbf{x}}[w]$, with β being a free parameter. Then the λ_k in the expressions of the Green's function in the third column of Table M12.9 must be replaced by $\lambda_k - \beta$; just as previously, the λ_k and $u_k(\mathbf{x})$ were determined by solving the eigenvalue problem (M12.11.1.1), (M12.11.1.2).

M12.11. Duhamel's Principles in Nonstationary Problems

M12.11.1. Problems for Homogeneous Linear Equations

► **Parabolic equations with two independent variables.** Consider the problem for the homogeneous linear equation of parabolic type

$$\frac{\partial w}{\partial t} = a(x)\frac{\partial^2 w}{\partial x^2} + b(x)\frac{\partial w}{\partial x} + c(x)w \qquad \text{(M12.11.1.1)}$$

with the homogeneous initial condition

$$w = 0 \quad \text{at} \quad t = 0 \tag{M12.11.1.2}$$

and the boundary conditions

$$s_1 \partial_x w + k_1 w = g(t) \quad \text{at} \quad x = x_1, \tag{M12.11.1.3}$$

$$s_2 \partial_x w + k_2 w = 0 \quad \text{at} \quad x = x_2. \tag{M12.11.1.4}$$

By appropriately choosing the values of the coefficients s_1, s_2, k_1, and k_2 in (M12.11.1.3) and (M12.11.1.4), one can obtain the first, second, third, and mixed boundary value problems for equation (M12.11.1.1).

The solution of problem (M12.11.1.1)–(M12.11.1.4) with the nonstationary boundary condition (M12.11.1.3) at $x = x_1$ can be expressed by the formula (*Duhamel's first principle*)

$$w(x,t) = \frac{\partial}{\partial t} \int_0^t u(x, t - \tau)\, g(\tau)\, d\tau = \int_0^t \frac{\partial u}{\partial t}(x, t - \tau)\, g(\tau)\, d\tau \tag{M12.11.1.5}$$

in terms of the solution $u(x,t)$ of the auxiliary problem for equation (M12.11.1.1) with the initial and boundary conditions (M12.11.1.2) and (M12.11.1.4), for u instead of w, and the following simpler stationary boundary condition at $x = x_1$:

$$s_1 \partial_x u + k_1 u = 1 \quad \text{at} \quad x = x_1. \tag{M12.11.1.6}$$

Remark. A similar formula also holds for the homogeneous boundary condition at $x = x_1$ and a nonhomogeneous nonstationary boundary condition at $x = x_2$.

Example. Consider the first boundary value problem for the heat equation

$$\frac{\partial w}{\partial t} = \frac{\partial^2 w}{\partial x^2} \tag{M12.11.1.7}$$

with the homogeneous initial condition (M12.11.1.2) and the boundary condition

$$w = g(t) \quad \text{at} \quad x = 0. \tag{M12.11.1.8}$$

(The second boundary condition is not required, since $0 \le x < \infty$ in this case.)

First consider the following auxiliary problem for the heat equation with the homogeneous initial condition and a simpler boundary condition:

$$\frac{\partial u}{\partial t} = \frac{\partial^2 u}{\partial x^2}, \qquad u = 0 \quad \text{at} \quad t = 0, \qquad u = 1 \quad \text{at} \quad x = 0.$$

This problem has a self-similar solution of the form

$$w = w(z), \qquad z = x t^{-1/2},$$

where the function $w(z)$ is determined by the following ordinary differential equation and boundary conditions:

$$u''_{zz} + \tfrac{1}{2} z u'_z = 0, \qquad u = 1 \quad \text{at} \quad z = 0, \qquad u = 0 \quad \text{at} \quad z = \infty.$$

Its solution is expressed as

$$u(z) = \operatorname{erfc}\left(\frac{z}{2}\right) \quad \Longrightarrow \quad u(x,t) = \operatorname{erfc}\left(\frac{x}{2\sqrt{t}}\right),$$

where $\operatorname{erfc} z = \frac{2}{\sqrt{\pi}} \int_z^\infty \exp(-\xi^2)\, d\xi$ is the complementary error function. Substituting the obtained expression of $u(x,t)$ into (M12.11.1.5), we obtain the solution to the first boundary value problem for the heat equation (M12.11.1.7) with the initial condition (M12.11.1.2) and an arbitrary boundary condition (M12.11.1.8) in the form

$$w(x,t) = \frac{x}{2\sqrt{\pi}} \int_0^t \exp\left[-\frac{x^2}{4(t-\tau)}\right] \frac{g(\tau)\, d\tau}{(t-\tau)^{3/2}}.$$

► **Hyperbolic equations with two independent variables.** Consider the problem for the homogeneous linear hyperbolic equation

$$\frac{\partial^2 w}{\partial t^2} + \varphi(x)\frac{\partial w}{\partial t} = a(x)\frac{\partial^2 w}{\partial x^2} + b(x)\frac{\partial w}{\partial x} + c(x)w \tag{M12.11.1.9}$$

with the homogeneous initial conditions

$$\begin{aligned} w &= 0 \quad \text{at} \quad t = 0,\\ \partial_t w &= 0 \quad \text{at} \quad t = 0, \end{aligned} \tag{M12.11.1.10}$$

and the boundary conditions (M12.11.1.3) and (M12.11.1.4).

The solution of problem (M12.11.1.9), (M12.11.1.10), (M12.11.1.3), (M12.11.1.4) with the nonstationary boundary condition (M12.11.1.3) at $x = x_1$ can be expressed by formula (M12.11.1.5) in terms of the solution $u(x, t)$ of the auxiliary problem for equation (M12.11.1.9) with the initial conditions (M12.11.1.10) and boundary condition (M12.11.1.4), for u instead of w, and the simpler stationary boundary condition (M12.11.1.6) at $x = x_1$.

In this case, the remark made after the boundary condition (M12.11.1.6) remains valid.

M12.11.2. Problems for Nonhomogeneous Linear Equations

► **Parabolic equations.** The solution of the nonhomogeneous linear equation

$$\frac{\partial w}{\partial t} = \sum_{i,j=1}^{n} a_{ij}(\mathbf{x})\frac{\partial^2 w}{\partial x_i \partial x_j} + \sum_{i=1}^{n} b_i(\mathbf{x})\frac{\partial w}{\partial x_i} + c(\mathbf{x})w + \Phi(\mathbf{x}, t)$$

with the homogeneous initial condition (M12.11.1.2) and the homogeneous boundary condition

$$\Gamma_{\mathbf{x}}[w] = 0 \quad \text{for} \quad \mathbf{x} \in S \tag{M12.11.2.1}$$

can be represented in the form (*Duhamel's second principle*)

$$w(\mathbf{x}, t) = \int_0^t U(\mathbf{x}, t - \tau, \tau)\, d\tau. \tag{M12.11.2.2}$$

Here, $U(\mathbf{x}, t, \tau)$ is the solution of the auxiliary problem for the homogeneous equation

$$\frac{\partial U}{\partial t} = \sum_{i,j=1}^{n} a_{ij}(\mathbf{x})\frac{\partial^2 U}{\partial x_i \partial x_j} + \sum_{i=1}^{n} b_i(\mathbf{x})\frac{\partial U}{\partial x_i} + c(\mathbf{x})U$$

with the boundary condition (M12.11.2.1), in which w must be substituted by U, and the nonhomogeneous initial condition

$$U = \Phi(\mathbf{x}, \tau) \quad \text{at} \quad t = 0,$$

where τ is a parameter.

Note that (M12.11.2.1) can represent a boundary condition of the first, second, or third kind; the coefficients of the operator $\Gamma_{\mathbf{x}}$ are assumed to be independent of t.

► **Hyperbolic equations.** The solution of the nonhomogeneous linear equation

$$\frac{\partial^2 w}{\partial t^2}+\varphi(\mathbf{x})\frac{\partial w}{\partial t}=\sum_{i,j=1}^{n}a_{ij}(\mathbf{x})\frac{\partial^2 w}{\partial x_i\partial x_j}+\sum_{i=1}^{n}b_i(\mathbf{x})\frac{\partial w}{\partial x_i}+c(\mathbf{x})w+\Phi(\mathbf{x},t)$$

with the homogeneous initial conditions (M12.11.1.10) and homogeneous boundary condition (M12.11.2.1) can be expressed by formula (M12.11.2.2) in terms of the solution $U=U(\mathbf{x},t,\tau)$ of the auxiliary problem for the homogeneous equation

$$\frac{\partial^2 U}{\partial t^2}+\varphi(\mathbf{x})\frac{\partial U}{\partial t}=\sum_{i,j=1}^{n}a_{ij}(\mathbf{x})\frac{\partial^2 U}{\partial x_i\partial x_j}+\sum_{i=1}^{n}b_i(\mathbf{x})\frac{\partial U}{\partial x_i}+c(\mathbf{x})U$$

with the homogeneous initial and boundary conditions, (M12.11.1.2) and (M12.11.2.1), where w must be replaced by U, and the nonhomogeneous initial condition

$$\partial_t U=\Phi(\mathbf{x},\tau)\quad\text{at}\quad t=0,$$

where τ is a parameter.

Note that (M12.11.2.1) can represent a boundary condition of the first, second, or third kind.

Chapter M13

Special Functions and Their Properties

Throughout Chapter M13 it is assumed that n is a positive integer unless otherwise specified.

M13.1. Some Coefficients, Symbols, and Numbers

M13.1.1. Factorials. Binomial Coefficients. Pochhammer Symbol

► **Factorial.**
$0! = 1! = 1,\ n! = 1\cdot 2\cdot 3\dots(n-1)n,\quad n = 2,\ 3,\ 4,\ \dots$

► **Double factorial.**
$0!! = 1!! = 1,\ (2n)!! = 2\cdot 4\cdot 6\dots(2n),\ (2n+1)!! = 1\cdot 3\cdot 5\dots(2n+1)$, where $n = 1,\ 2,\ 3,\ \dots$

► **Binomial coefficients.**

$$C_n^k = \binom{n}{k} = \frac{n!}{k!\,(n-k)!},\quad \text{where}\quad k = 1,\dots,n;$$

$$C_a^0 = 1,\quad C_a^k = \binom{a}{k} = \frac{a(a-1)\dots(a-k+1)}{k!},\quad \text{where}\quad k = 1,2,\dots$$

Here, a is an arbitrary real number.

Remark. In various texts, the binomial coefficients are also denoted $C_r^n = {}_nC_r = C(n,r)$.

► **Generalization. Some properties.** General case:

$$C_a^b = \frac{\Gamma(a+1)}{\Gamma(b+1)\Gamma(a-b+1)},\quad \text{where}\ \Gamma(x)\ \text{is the gamma function.}$$

Properties:

$$C_a^0 = 1,\quad C_n^k = 0\quad \text{for}\ k = -1,-2,\dots\ \text{or}\ k > n,$$

$$C_a^{b+1} = \frac{a}{b+1}C_{a-1}^b = \frac{a-b}{b+1}C_a^b,\quad C_a^b + C_a^{b+1} = C_{a+1}^{b+1},$$

$$C_{-1/2}^n = \frac{(-1)^n}{2^{2n}}C_{2n}^n = (-1)^n\frac{(2n-1)!!}{(2n)!!},$$

$$C_{1/2}^n = \frac{(-1)^{n-1}}{n2^{2n-1}}C_{2n-2}^{n-1} = \frac{(-1)^{n-1}}{n}\frac{(2n-3)!!}{(2n-2)!!},$$

$$C_{n+1/2}^{2n+1} = (-1)^n 2^{-4n-1}C_{2n}^n,\quad C_{2n+1/2}^n = 2^{-2n}C_{4n+1}^{2n},$$

$$C_n^{1/2} = \frac{2^{2n+1}}{\pi C_{2n}^n},\quad C_n^{n/2} = \frac{2^{2n}}{\pi}C_n^{(n-1)/2}.$$

► **Pochhammer symbol.**

$$(a)_n = a(a+1)\dots(a+n-1) = \frac{\Gamma(a+n)}{\Gamma(a)} = (-1)^n\frac{\Gamma(1-a)}{\Gamma(1-a-n)}.$$

M13.1.2. Bernoulli Numbers

► **Definition.** The *Bernoulli numbers* are defined by the recurrence relation

$$B_0 = 1, \qquad \sum_{k=0}^{n-1} C_n^k B_k = 0, \quad n = 2,\ 3,\ \dots$$

Numerical values:

$$B_0 = 1, \quad B_1 = -\tfrac{1}{2}, \quad B_2 = \tfrac{1}{6}, \quad B_4 = -\tfrac{1}{30}, \quad B_6 = \tfrac{1}{42}, \quad B_8 = -\tfrac{1}{30}, \quad B_{10} = \tfrac{5}{66}, \quad \dots,$$
$$B_{2m+1} = 0 \quad \text{for} \quad m = 1, 2, \dots$$

All odd-numbered Bernoulli numbers but B_1 are zero; all even-numbered Bernoulli numbers have alternating signs.

► **Generating function.**

$$\frac{x}{e^x - 1} = \sum_{n=0}^{\infty} B_n \frac{x^n}{n!}, \qquad |x| < 2\pi.$$

This relation may be regarded as a definition of the Bernoulli numbers.

M13.2. Error Functions. Exponential and Logarithmic Integrals

M13.2.1. Error Function and Complementary Error Function

► **Integral representations.** Definitions:

$$\operatorname{erf} x = \frac{2}{\sqrt{\pi}} \int_0^x \exp(-t^2)\,dt \quad \text{(error function, also called probability integral)},$$
$$\operatorname{erfc} x = 1 - \operatorname{erf} x = \frac{2}{\sqrt{\pi}} \int_x^{\infty} \exp(-t^2)\,dt \quad \text{(complementary error function)}.$$

Properties:

$$\operatorname{erf}(-x) = -\operatorname{erf} x; \quad \operatorname{erf}(0) = 0, \quad \operatorname{erf}(\infty) = 1; \quad \operatorname{erfc}(0) = 1, \quad \operatorname{erfc}(\infty) = 0.$$

► **Expansions as $x \to 0$ and $x \to \infty$. Definite integral.** Expansion of erf x into series in powers of x as $x \to 0$:

$$\operatorname{erf} x = \frac{2}{\sqrt{\pi}} \sum_{k=0}^{\infty} (-1)^k \frac{x^{2k+1}}{k!\,(2k+1)} = \frac{2}{\sqrt{\pi}} \exp\bigl(-x^2\bigr) \sum_{k=0}^{\infty} \frac{2^k x^{2k+1}}{(2k+1)!!}.$$

Asymptotic expansion of erfc x as $x \to \infty$:

$$\operatorname{erfc} x = \frac{1}{\sqrt{\pi}} \exp\bigl(-x^2\bigr) \left[\sum_{m=0}^{M-1} (-1)^m \frac{\left(\frac{1}{2}\right)_m}{x^{2m+1}} + O\bigl(|x|^{-2M-1}\bigr)\right], \qquad M = 1, 2, \dots$$

Integral:

$$\int_0^x \operatorname{erf} t\,dt = x \operatorname{erf} x - \frac{1}{2} + \frac{1}{2}\exp(-x^2).$$

M13.2.2. Exponential Integral

► **Integral representations.** Definition:

$$\operatorname{Ei}(x) = \int_{-\infty}^{x} \frac{e^t}{t}\,dt = -\int_{-x}^{\infty} \frac{e^{-t}}{t}\,dt \qquad \text{for} \quad x < 0,$$

$$\operatorname{Ei}(x) = \lim_{\varepsilon\to+0}\left(\int_{-\infty}^{-\varepsilon} \frac{e^t}{t}\,dt + \int_{\varepsilon}^{x} \frac{e^t}{t}\,dt\right) \qquad \text{for} \quad x > 0.$$

Other integral representations:

$$\operatorname{Ei}(-x) = -e^{-x}\int_0^\infty \frac{x\sin t + t\cos t}{x^2+t^2}\,dt \quad \text{for} \quad x > 0,$$

$$\operatorname{Ei}(-x) = e^{-x}\int_0^\infty \frac{x\sin t - t\cos t}{x^2+t^2}\,dt \quad \text{for} \quad x < 0.$$

► **Expansions as $x \to 0$ and $x \to \infty$.** Expansion into series in powers of x as $x \to 0$:

$$\operatorname{Ei}(x) = \begin{cases} \mathcal{C} + \ln(-x) + \displaystyle\sum_{k=1}^{\infty} \frac{x^k}{k!\,k} & \text{if } x < 0, \\ \mathcal{C} + \ln x + \displaystyle\sum_{k=1}^{\infty} \frac{x^k}{k!\,k} & \text{if } x > 0, \end{cases}$$

where $\mathcal{C} = 0.5772\ldots$ is the Euler constant.

Asymptotic expansion as $x \to \infty$:

$$\operatorname{Ei}(-x) = e^{-x}\sum_{k=1}^{n}(-1)^k\frac{(k-1)!}{x^k} + R_n, \qquad R_n < \frac{n!}{x^n}.$$

M13.2.3. Logarithmic Integral

► **Integral representations.** Definition:

$$\operatorname{li}(x) = \begin{cases} \displaystyle\int_0^x \frac{dt}{\ln t} & \text{if } 0 < x < 1, \\ \displaystyle\lim_{\varepsilon\to+0}\left(\int_0^{1-\varepsilon} \frac{dt}{\ln t} + \int_{1+\varepsilon}^{x} \frac{dt}{\ln t}\right) & \text{if } x > 1. \end{cases}$$

► **Limiting properties. Relation to the exponential integral.** For small x,

$$\operatorname{li}(x) \approx \frac{x}{\ln(1/x)}.$$

For large x,

$$\operatorname{li}(x) \approx \frac{x}{\ln x}.$$

Asymptotic expansion as $x \to 1$:

$$\operatorname{li}(x) = \mathcal{C} + \ln|\ln x| + \sum_{k=1}^{\infty} \frac{\ln^k x}{k!\,k}, \qquad \mathcal{C} = 0.5772\ldots$$

M13.3. Sine Integral and Cosine Integral. Fresnel Integrals

M13.3.1. Sine Integral

► **Integral representations. Properties.** Definition:

$$\operatorname{Si}(x)=\int_0^x \frac{\sin t}{t}\,dt, \qquad \operatorname{si}(x)=-\int_x^\infty \frac{\sin t}{t}\,dt=\operatorname{Si}(x)-\frac{\pi}{2}.$$

Specific values:

$$\operatorname{Si}(0)=0, \quad \operatorname{Si}(\infty)=\frac{\pi}{2}, \quad \operatorname{si}(\infty)=0.$$

Properties:

$$\operatorname{Si}(-x)=-\operatorname{Si}(x), \quad \operatorname{si}(x)+\operatorname{si}(-x)=-\pi, \quad \lim_{x\to-\infty}\operatorname{si}(x)=-\pi.$$

► **Expansions as $x \to 0$ and $x \to \infty$.** Expansion into series in powers of x as $x \to 0$:

$$\operatorname{Si}(x)=\sum_{k=1}^{\infty}\frac{(-1)^{k+1}x^{2k-1}}{(2k-1)\,(2k-1)!}.$$

Asymptotic expansion as $x \to \infty$:

$$\operatorname{si}(x)=-\cos x\left[\sum_{m=0}^{M-1}\frac{(-1)^m(2m)!}{x^{2m+1}}+O\bigl(|x|^{-2M-1}\bigr)\right]+\sin x\left[\sum_{m=1}^{N-1}\frac{(-1)^m(2m-1)!}{x^{2m}}+O\bigl(|x|^{-2N}\bigr)\right],$$

where $M, N = 1, 2, \dots$

M13.3.2. Cosine Integral

► **Integral representations.** Definition:

$$\operatorname{Ci}(x)=-\int_x^\infty \frac{\cos t}{t}\,dt=\mathcal{C}+\ln x+\int_0^x \frac{\cos t-1}{t}\,dt,$$

where $\mathcal{C}=0.5772\dots$ is the Euler constant.

► **Expansions as $x \to 0$ and $x \to \infty$.** Expansion into series in powers of x as $x \to 0$:

$$\operatorname{Ci}(x)=\mathcal{C}+\ln x+\sum_{k=1}^{\infty}\frac{(-1)^k x^{2k}}{2k\,(2k)!}.$$

Asymptotic expansion as $x \to \infty$:

$$\operatorname{Ci}(x)=\cos x\left[\sum_{m=1}^{M-1}\frac{(-1)^m(2m-1)!}{x^{2m}}+O\bigl(|x|^{-2M}\bigr)\right]+\sin x\left[\sum_{m=0}^{N-1}\frac{(-1)^m(2m)!}{x^{2m+1}}+O\bigl(|x|^{-2N-1}\bigr)\right],$$

where $M, N = 2, 3, \dots$

M13.3.3. Fresnel Integrals

► **Integral representations.** Definitions:

$$S(x) = \frac{1}{\sqrt{2\pi}} \int_0^x \frac{\sin t}{\sqrt{t}}\,dt = \sqrt{\frac{2}{\pi}} \int_0^{\sqrt{x}} \sin t^2\,dt,$$
$$C(x) = \frac{1}{\sqrt{2\pi}} \int_0^x \frac{\cos t}{\sqrt{t}}\,dt = \sqrt{\frac{2}{\pi}} \int_0^{\sqrt{x}} \cos t^2\,dt.$$

► **Expansions as $x \to 0$ and $x \to \infty$.** Expansion into series in powers of x as $x \to 0$:

$$S(x) = \sqrt{\frac{2}{\pi}}\, x \sum_{k=0}^{\infty} \frac{(-1)^k x^{2k+1}}{(4k+3)\,(2k+1)!},$$
$$C(x) = \sqrt{\frac{2}{\pi}}\, x \sum_{k=0}^{\infty} \frac{(-1)^k x^{2k}}{(4k+1)\,(2k)!}.$$

Asymptotic expansion as $x \to \infty$:

$$S(x) = \frac{1}{2} - \frac{\cos x}{\sqrt{2\pi x}} P(x) - \frac{\sin x}{\sqrt{2\pi x}} Q(x),$$
$$C(x) = \frac{1}{2} + \frac{\sin x}{\sqrt{2\pi x}} P(x) - \frac{\cos x}{\sqrt{2\pi x}} Q(x),$$
$$P(x) = 1 - \frac{1\times 3}{(2x)^2} + \frac{1\times 3\times 5\times 7}{(2x)^4} - \cdots, \quad Q(x) = \frac{1}{2x} - \frac{1\times 3\times 5}{(2x)^3} + \cdots.$$

M13.4. Gamma Function, Psi Function, and Beta Function

M13.4.1. Gamma Function

► **Integral representations. Simplest properties.** The gamma function, $\Gamma(z)$, is an analytic function of the complex argument z everywhere except for the points $z = 0, -1, -2, \ldots$

For $\operatorname{Re} z > 0$,

$$\Gamma(z) = \int_0^{\infty} t^{z-1} e^{-t}\,dt.$$

For $-(n+1) < \operatorname{Re} z < -n$, where $n = 0, 1, 2, \ldots$,

$$\Gamma(z) = \int_0^{\infty} \left[e^{-t} - \sum_{m=0}^{n} \frac{(-1)^m}{m!} \right] t^{z-1}\,dt.$$

Simplest properties:

$$\Gamma(z+1) = z\Gamma(z), \quad \Gamma(n+1) = n!, \quad \Gamma(1) = \Gamma(2) = 1.$$

Fractional values of the argument:

$$\Gamma\Big(\frac{1}{2}\Big) = \sqrt{\pi}, \qquad \Gamma\Big(n+\frac{1}{2}\Big) = \frac{\sqrt{\pi}}{2^n}(2n-1)!!,$$
$$\Gamma\Big(-\frac{1}{2}\Big) = -2\sqrt{\pi}, \quad \Gamma\Big(\frac{1}{2}-n\Big) = (-1)^n\frac{2^n\sqrt{\pi}}{(2n-1)!!}.$$

► **Euler, Stirling, and other formulas.** Euler formula

$$\Gamma(z) = \lim_{n\to\infty}\frac{n!\,n^z}{z(z+1)\dots(z+n)} \qquad (z \neq 0, -1, -2, \dots).$$

Symmetry formulas:

$$\Gamma(z)\Gamma(-z) = -\frac{\pi}{z\sin(\pi z)}, \quad \Gamma(z)\Gamma(1-z) = \frac{\pi}{\sin(\pi z)},$$
$$\Gamma\Big(\frac{1}{2}+z\Big)\Gamma\Big(\frac{1}{2}-z\Big) = \frac{\pi}{\cos(\pi z)}.$$

Multiple argument formulas:

$$\Gamma(2z) = \frac{2^{2z-1}}{\sqrt{\pi}}\Gamma(z)\Gamma\Big(z+\frac{1}{2}\Big),$$
$$\Gamma(3z) = \frac{3^{3z-1/2}}{2\pi}\Gamma(z)\Gamma\Big(z+\frac{1}{3}\Big)\Gamma\Big(z+\frac{2}{3}\Big),$$
$$\Gamma(nz) = (2\pi)^{(1-n)/2}n^{nz-1/2}\prod_{k=0}^{n-1}\Gamma\Big(z+\frac{k}{n}\Big).$$

Asymptotic expansion (*Stirling formula*):

$$\Gamma(z) = \sqrt{2\pi}\,e^{-z}z^{z-1/2}\big[1+\tfrac{1}{12}z^{-1}+\tfrac{1}{288}z^{-2}+O(z^{-3})\big] \qquad (|\arg z| < \pi).$$

M13.4.2. Psi Function (Digamma Function)

Definition:

$$\psi(z) = \frac{d\ln\Gamma(z)}{dz} = \frac{\Gamma'_z(z)}{\Gamma(z)}.$$

The psi function is the logarithmic derivative of the gamma function and is also called the *digamma function*.

Integral representations ($\operatorname{Re} z > 0$):

$$\psi(z) = \int_0^\infty \big[e^{-t}-(1+t)^{-z}\big]t^{-1}\,dt,$$
$$\psi(z) = \ln z + \int_0^\infty \big[t^{-1}-(1-e^{-t})^{-1}\big]e^{-tz}\,dt,$$
$$\psi(z) = -\mathcal{C} + \int_0^1 \frac{1-t^{z-1}}{1-t}\,dt,$$

where $\mathcal{C} = -\psi(1) = 0.5772\dots$ is the Euler constant.

Values for integer argument:

$$\psi(1) = -\mathcal{C}, \qquad \psi(n) = -\mathcal{C} + \sum_{k=1}^{n-1} k^{-1} \quad (n = 2, 3, \dots).$$

Asymptotic expansion as $z \to \infty$ ($|\arg z| < \pi$):

$$\psi(z) = \ln z - \frac{1}{2z} - \frac{1}{12z^2} + \frac{1}{120z^4} - \frac{1}{252z^6} + \cdots = \ln z - \frac{1}{2z} - \sum_{n=1}^{\infty} \frac{B_{2n}}{2nz^{2n}},$$

where the B_{2n} are Bernoulli numbers.

M13.4.3. Beta Function

► **Integral representation. Relationship with the gamma function.** Definition:

$$B(x, y) = \int_0^1 t^{x-1}(1-t)^{y-1}\,dt,$$

where $\operatorname{Re} x > 0$ and $\operatorname{Re} y > 0$.

Relationship with the gamma function:

$$B(x, y) = \frac{\Gamma(x)\Gamma(y)}{\Gamma(x+y)}.$$

► **Some properties.**

$$\begin{aligned}
&B(x, y) = B(y, x);\\
&B(x, y+1) = \frac{y}{x} B(x+1, y) = \frac{y}{x+y} B(x, y);\\
&B(x, 1-x) = \frac{\pi}{\sin(\pi x)}, \quad 0 < x < 1;\\
&\frac{1}{B(n, m)} = mC_{n+m-1}^{n-1} = nC_{n+m-1}^{m-1} = mC_{n+m-1}^{m} = nC_{n+m-1}^{n},
\end{aligned}$$

where n and m are positive integers.

M13.5. Incomplete Gamma Function

M13.5.1. Integral Representations. Recurrence Formulas

Definitions:

$$\gamma(\alpha, x) = \int_0^x e^{-t} t^{\alpha-1}\,dt, \qquad \operatorname{Re} \alpha > 0,$$

$$\Gamma(\alpha, x) = \int_x^\infty e^{-t} t^{\alpha-1}\,dt = \Gamma(\alpha) - \gamma(\alpha, x).$$

Recurrence formulas:

$$\begin{aligned}
&\gamma(\alpha+1, x) = \alpha\gamma(\alpha, x) - x^\alpha e^{-x},\\
&\gamma(\alpha+1, x) = (x+\alpha)\gamma(\alpha, x) + (1-\alpha)x\gamma(\alpha-1, x),\\
&\Gamma(\alpha+1, x) = \alpha\Gamma(\alpha, x) + x^\alpha e^{-x}.
\end{aligned}$$

Special cases:

$$\gamma(n+1,x) = n!\left[1 - e^{-x}\left(\sum_{k=0}^{n}\frac{x^k}{k!}\right)\right], \qquad n = 0,\ 1,\ \dots;$$

$$\Gamma(n+1,x) = n!\,e^{-x}\sum_{k=0}^{n}\frac{x^k}{k!}, \qquad n = 0,\ 1,\ \dots;$$

$$\Gamma(-n,x) = \frac{(-1)^n}{n!}\left[\Gamma(0,x) - e^{-x}\sum_{k=0}^{n-1}(-1)^k\frac{k!}{x^{k+1}}\right], \quad n = 1,\ 2,\ \dots$$

M13.5.2. Expansions as $x \to 0$ and $x \to \infty$. Relation to Other Functions

Asymptotic expansions as $x \to 0$:

$$\gamma(\alpha,x) = \sum_{n=0}^{\infty}\frac{(-1)^n x^{\alpha+n}}{n!\,(\alpha+n)},$$

$$\Gamma(\alpha,x) = \Gamma(\alpha) - \sum_{n=0}^{\infty}\frac{(-1)^n x^{\alpha+n}}{n!\,(\alpha+n)}.$$

Asymptotic expansions as $x \to \infty$:

$$\gamma(\alpha,x) = \Gamma(\alpha) - x^{\alpha-1}e^{-x}\left[\sum_{m=0}^{M-1}\frac{(1-\alpha)_m}{(-x)^m} + O\big(|x|^{-M}\big)\right], \qquad M = 1,2,\dots;$$

$$\Gamma(\alpha,x) = x^{\alpha-1}e^{-x}\left[\sum_{m=0}^{M-1}\frac{(1-\alpha)_m}{(-x)^m} + O\big(|x|^{-M}\big)\right] \qquad \big(-\tfrac{3}{2}\pi < \arg x < \tfrac{3}{2}\pi\big).$$

Representation of the error function, complementary error function, and exponential integral in terms of the gamma functions:

$$\operatorname{erf} x = \frac{1}{\sqrt{\pi}}\gamma\Big(\frac{1}{2},\ x^2\Big), \quad \operatorname{erfc} x = \frac{1}{\sqrt{\pi}}\Gamma\Big(\frac{1}{2},\ x^2\Big), \quad \operatorname{Ei}(-x) = -\Gamma(0,x).$$

M13.6. Bessel Functions (Cylinder Functions)

M13.6.1. Definitions and Basic Formulas

► **Bessel functions of the first and the second kind.** The *Bessel function of the first kind*, $J_\nu(x)$, and the *Bessel function of the second kind*, $Y_\nu(x)$ (also called the *Neumann function*), are solutions of the Bessel equation

$$x^2 y''_{xx} + x y'_x + (x^2 - \nu^2)y = 0$$

and are defined by the formulas

$$J_\nu(x) = \sum_{k=0}^{\infty}\frac{(-1)^k (x/2)^{\nu+2k}}{k!\,\Gamma(\nu+k+1)}, \quad Y_\nu(x) = \frac{J_\nu(x)\cos\pi\nu - J_{-\nu}(x)}{\sin\pi\nu}. \tag{M13.6.1.1}$$

The formula for $Y_\nu(x)$ is valid for $\nu \neq 0, \pm1, \pm2, \dots$ (the cases $\nu = 0, \pm1, \pm2, \dots$ are discussed in what follows).

The general solution of the Bessel equation has the form $Z_\nu(x) = C_1 J_\nu(x) + C_2 Y_\nu(x)$ and is called a *cylinder function*.

► **Some formulas.**

$$2\nu Z_\nu(x) = x[Z_{\nu-1}(x) + Z_{\nu+1}(x)],$$

$$\frac{d}{dx} Z_\nu(x) = \frac{1}{2}[Z_{\nu-1}(x) - Z_{\nu+1}(x)] = \pm\left[\frac{\nu}{x} Z_\nu(x) - Z_{\nu\pm1}(x)\right],$$

$$\frac{d}{dx}[x^\nu Z_\nu(x)] = x^\nu Z_{\nu-1}(x), \qquad \frac{d}{dx}[x^{-\nu} Z_\nu(x)] = -x^{-\nu} Z_{\nu+1}(x),$$

$$\left(\frac{1}{x}\frac{d}{dx}\right)^n [x^\nu J_\nu(x)] = x^{\nu-n} J_{\nu-n}(x), \qquad \left(\frac{1}{x}\frac{d}{dx}\right)^n [x^{-\nu} J_\nu(x)] = (-1)^n x^{-\nu-n} J_{\nu+n}(x).$$

► **Bessel functions for $\nu = \pm n \pm \frac{1}{2}$, where $n = 0, 1, 2, \ldots$**

$$J_{1/2}(x) = \sqrt{\frac{2}{\pi x}} \sin x, \qquad J_{-1/2}(x) = \sqrt{\frac{2}{\pi x}} \cos x,$$

$$J_{3/2}(x) = \sqrt{\frac{2}{\pi x}} \left(\frac{1}{x} \sin x - \cos x\right), \qquad J_{-3/2}(x) = \sqrt{\frac{2}{\pi x}} \left(-\frac{1}{x} \cos x - \sin x\right),$$

$$J_{n+1/2}(x) = \sqrt{\frac{2}{\pi x}} \left[\sin\left(x - \frac{n\pi}{2}\right) \sum_{k=0}^{[n/2]} \frac{(-1)^k (n+2k)!}{(2k)!\,(n-2k)!\,(2x)^{2k}} \right.$$
$$\left. + \cos\left(x - \frac{n\pi}{2}\right) \sum_{k=0}^{[(n-1)/2]} \frac{(-1)^k (n+2k+1)!}{(2k+1)!\,(n-2k-1)!\,(2x)^{2k+1}}\right],$$

$$J_{-n-1/2}(x) = \sqrt{\frac{2}{\pi x}} \left[\cos\left(x + \frac{n\pi}{2}\right) \sum_{k=0}^{[n/2]} \frac{(-1)^k (n+2k)!}{(2k)!\,(n-2k)!\,(2x)^{2k}} \right.$$
$$\left. - \sin\left(x + \frac{n\pi}{2}\right) \sum_{k=0}^{[(n-1)/2]} \frac{(-1)^k (n+2k+1)!}{(2k+1)!\,(n-2k-1)!\,(2x)^{2k+1}}\right],$$

$$Y_{1/2}(x) = -\sqrt{\frac{2}{\pi x}} \cos x, \qquad Y_{-1/2}(x) = \sqrt{\frac{2}{\pi x}} \sin x,$$

$$Y_{n+1/2}(x) = (-1)^{n+1} J_{-n-1/2}(x), \qquad Y_{-n-1/2}(x) = (-1)^n J_{n+1/2}(x),$$

where $[A]$ stands for the integer part of the number A.

► **Bessel functions for $\nu = \pm n$, where $n = 0, 1, 2, \ldots$** Let $\nu = n$ be an arbitrary integer. The relations

$$J_{-n}(x) = (-1)^n J_n(x), \qquad Y_{-n}(x) = (-1)^n Y_n(x)$$

are valid. The function $J_n(x)$ is given by the first formula in (M13.6.1.1) with $\nu = n$, and $Y_n(x)$ can be obtained from the second formula in (M13.6.1.1) by passing to the limit $\nu \to n$. For nonnegative n, $Y_n(x)$ can be represented in the form

$$Y_n(x) = \frac{2}{\pi} J_n(x) \ln\frac{x}{2} - \frac{1}{\pi} \sum_{k=0}^{n-1} \frac{(n-k-1)!}{k!} \left(\frac{2}{x}\right)^{n-2k} - \frac{1}{\pi} \sum_{k=0}^{\infty} (-1)^k \left(\frac{x}{2}\right)^{n+2k} \frac{\psi(k+1) + \psi(n+k+1)}{k!\,(n+k)!},$$

where $\psi(1) = -\mathcal{C}$, $\psi(n) = -\mathcal{C} + \sum\limits_{k=1}^{n-1} k^{-1}$, $\mathcal{C} = 0.5772\ldots$ is the Euler constant, and $\psi(x) = [\ln \Gamma(x)]'_x$ is the logarithmic derivative of the gamma function, also known as the digamma function (see Subsection M13.4.2).

► **Wronskians.**

$$W(J_\nu, J_{-\nu}) = -\frac{2}{\pi x}\sin(\pi\nu), \qquad W(J_\nu, Y_\nu) = \frac{2}{\pi x},$$

Here, the notation $W(f,g) = fg'_x - f'_x g$ is used.

M13.6.2. Integral Representations and Asymptotic Expansions

► **Integral representations.** The functions $J_\nu(x)$ and $Y_\nu(x)$ can be represented in the form of definite integrals (for $x > 0$):

$$\pi J_\nu(x) = \int_0^\pi \cos(x\sin\theta - \nu\theta)\,d\theta - \sin\pi\nu\int_0^\infty \exp(-x\sinh t - \nu t)\,dt,$$
$$\pi Y_\nu(x) = \int_0^\pi \sin(x\sin\theta - \nu\theta)\,d\theta - \int_0^\infty (e^{\nu t} + e^{-\nu t}\cos\pi\nu)\,e^{-x\sinh t}\,dt.$$

For $|\nu| < \frac{1}{2}$, $x > 0$,

$$J_\nu(x) = \frac{2^{1+\nu}x^{-\nu}}{\pi^{1/2}\Gamma(\frac{1}{2}-\nu)}\int_1^\infty \frac{\sin(xt)\,dt}{(t^2-1)^{\nu+1/2}},$$
$$Y_\nu(x) = -\frac{2^{1+\nu}x^{-\nu}}{\pi^{1/2}\Gamma(\frac{1}{2}-\nu)}\int_1^\infty \frac{\cos(xt)\,dt}{(t^2-1)^{\nu+1/2}}.$$

For $\nu > -\frac{1}{2}$,

$$J_\nu(x) = \frac{2(x/2)^\nu}{\pi^{1/2}\Gamma(\frac{1}{2}+\nu)}\int_0^{\pi/2}\cos(x\cos t)\sin^{2\nu}t\,dt \quad (\textit{Poisson's formula}).$$

For $\nu = 0$, $x > 0$,

$$J_0(x) = \frac{2}{\pi}\int_0^\infty \sin(x\cosh t)\,dt, \qquad Y_0(x) = -\frac{2}{\pi}\int_0^\infty \cos(x\cosh t)\,dt.$$

For integer $\nu = n = 0, 1, 2, \ldots,$

$$J_n(x) = \frac{1}{\pi}\int_0^\pi \cos(nt - x\sin t)\,dt \quad (\textit{Bessel's formula}),$$
$$J_{2n}(x) = \frac{2}{\pi}\int_0^{\pi/2}\cos(x\sin t)\cos(2nt)\,dt,$$
$$J_{2n+1}(x) = \frac{2}{\pi}\int_0^{\pi/2}\sin(x\sin t)\sin[(2n+1)t]\,dt.$$

► **Asymptotic expansions as $|x| \to \infty$.**

$$J_\nu(x) = \sqrt{\frac{2}{\pi x}}\left\{\cos\left(\frac{4x - 2\nu\pi - \pi}{4}\right)\left[\sum_{m=0}^{M-1}(-1)^m(\nu, 2m)(2x)^{-2m} + O(|x|^{-2M})\right]\right.$$

$$-\sin\Bigl(\frac{4x-2\nu\pi-\pi}{4}\Bigr)\biggl[\sum_{m=0}^{M-1}(-1)^m(\nu,2m+1)(2x)^{-2m-1}+O(|x|^{-2M-1})\biggr]\biggr\},$$

$$Y_\nu(x)=\sqrt{\frac{2}{\pi x}}\biggl\{\sin\Bigl(\frac{4x-2\nu\pi-\pi}{4}\Bigr)\biggl[\sum_{m=0}^{M-1}(-1)^m(\nu,2m)(2x)^{-2m}+O(|x|^{-2M})\biggr]$$

$$+\cos\Bigl(\frac{4x-2\nu\pi-\pi}{4}\Bigr)\biggl[\sum_{m=0}^{M-1}(-1)^m(\nu,2m+1)(2x)^{-2m-1}+O(|x|^{-2M-1})\biggr]\biggr\},$$

where $(\nu,m)=\dfrac{1}{2^{2m}m!}(4\nu^2-1)(4\nu^2-3^2)\dots[4\nu^2-(2m-1)^2]=\dfrac{\Gamma(\frac12+\nu+m)}{m!\,\Gamma(\frac12+\nu-m)}$.

For nonnegative integer n and large x,

$$\sqrt{\pi x}\,J_{2n}(x)=(-1)^n(\cos x+\sin x)+O(x^{-2}),$$
$$\sqrt{\pi x}\,J_{2n+1}(x)=(-1)^{n+1}(\cos x-\sin x)+O(x^{-2}).$$

► **Zeros of Bessel functions.** Each of the functions $J_\nu(x)$ and $Y_\nu(x)$ has infinitely many real zeros (for real ν). All zeros are simple, except possibly for the point $x=0$.

The zeros γ_m of $J_0(x)$, i.e., the roots of the equation $J_0(\gamma_m)=0$, are approximately given by

$$\gamma_m=2.4+3.13\,(m-1)\qquad(m=1,2,\dots),$$

with a maximum error of 0.2%.

M13.7. Modified Bessel Functions

M13.7.1. Definitions. Basic Formulas

► **Modified Bessel functions of the first and the second kind.** The *modified Bessel function of the first kind*, $I_\nu(x)$, and the *modified Bessel function of the second kind*, $K_\nu(x)$ (also called the *Macdonald function*), of order ν are solutions of the modified Bessel equation

$$x^2y''_{xx}+xy'_x-(x^2+\nu^2)y=0$$

and are defined by the formulas

$$I_\nu(x)=\sum_{k=0}^{\infty}\frac{(x/2)^{2k+\nu}}{k!\,\Gamma(\nu+k+1)},\qquad K_\nu(x)=\frac{\pi}{2}\frac{I_{-\nu}(x)-I_\nu(x)}{\sin(\pi\nu)},$$

(see below for $K_\nu(x)$ with $\nu=0,1,2,\dots$).

► **Some formulas.** The modified Bessel functions possess the following properties:

$$K_{-\nu}(x)=K_\nu(x);\qquad I_{-n}(x)=(-1)^nI_n(x),\quad n=0,1,2,\dots$$
$$2\nu I_\nu(x)=x[I_{\nu-1}(x)-I_{\nu+1}(x)],\qquad 2\nu K_\nu(x)=-x[K_{\nu-1}(x)-K_{\nu+1}(x)],$$
$$\frac{d}{dx}I_\nu(x)=\frac12[I_{\nu-1}(x)+I_{\nu+1}(x)],\qquad \frac{d}{dx}K_\nu(x)=-\frac12[K_{\nu-1}(x)+K_{\nu+1}(x)].$$

► **Modified Bessel functions for $\nu = \pm n \pm \frac{1}{2}$, where $n = 0, 1, 2, \dots$**

$$I_{1/2}(x) = \sqrt{\frac{2}{\pi x}}\sinh x, \qquad I_{-1/2}(x) = \sqrt{\frac{2}{\pi x}}\cosh x,$$

$$I_{3/2}(x) = \sqrt{\frac{2}{\pi x}}\left(-\frac{1}{x}\sinh x + \cosh x\right), \quad I_{-3/2}(x) = \sqrt{\frac{2}{\pi x}}\left(-\frac{1}{x}\cosh x + \sinh x\right),$$

$$I_{n+1/2}(x) = \frac{1}{\sqrt{2\pi x}}\left[e^x \sum_{k=0}^{n} \frac{(-1)^k (n+k)!}{k!\,(n-k)!\,(2x)^k} - (-1)^n e^{-x} \sum_{k=0}^{n} \frac{(n+k)!}{k!\,(n-k)!\,(2x)^k}\right],$$

$$I_{-n-1/2}(x) = \frac{1}{\sqrt{2\pi x}}\left[e^x \sum_{k=0}^{n} \frac{(-1)^k (n+k)!}{k!\,(n-k)!\,(2x)^k} + (-1)^n e^{-x} \sum_{k=0}^{n} \frac{(n+k)!}{k!\,(n-k)!\,(2x)^k}\right],$$

$$K_{\pm 1/2}(x) = \sqrt{\frac{\pi}{2x}}\,e^{-x}, \qquad K_{\pm 3/2}(x) = \sqrt{\frac{\pi}{2x}}\left(1 + \frac{1}{x}\right)e^{-x},$$

$$K_{n+1/2}(x) = K_{-n-1/2}(x) = \sqrt{\frac{\pi}{2x}}\,e^{-x} \sum_{k=0}^{n} \frac{(n+k)!}{k!\,(n-k)!\,(2x)^k}.$$

► **Modified Bessel functions for $\nu = n$, where $n = 0, 1, 2, \dots$** If $\nu = n$ is a nonnegative integer, then

$$\begin{aligned} K_n(x) = (-1)^{n+1} I_n(x) \ln\frac{x}{2} &+ \frac{1}{2}\sum_{m=0}^{n-1} (-1)^m \left(\frac{x}{2}\right)^{2m-n} \frac{(n-m-1)!}{m!} \\ &+ \frac{1}{2}(-1)^n \sum_{m=0}^{\infty} \left(\frac{x}{2}\right)^{n+2m} \frac{\psi(n+m+1) + \psi(m+1)}{m!\,(n+m)!}; \quad n = 0, 1, 2, \dots, \end{aligned}$$

where $\psi(z)$ is the logarithmic derivative of the gamma function; for $n = 0$, the first sum is omitted.

► **Wronskians.**

$$W(I_\nu, I_{-\nu}) = -\frac{2}{\pi x}\sin(\pi\nu), \qquad W(I_\nu, K_\nu) = -\frac{1}{x},$$

where $W(f, g) = f g'_x - f'_x g$.

M13.7.2. Integral Representations and Asymptotic Expansions

► **Integral representations.** The functions $I_\nu(x)$ and $K_\nu(x)$ can be represented in terms of definite integrals:

$$I_\nu(x) = \frac{x^\nu}{\pi^{1/2} 2^\nu \Gamma(\nu + \frac{1}{2})} \int_{-1}^{1} \exp(-xt)(1 - t^2)^{\nu - 1/2}\,dt \qquad (x > 0,\ \nu > -\tfrac{1}{2}),$$

$$K_\nu(x) = \int_0^\infty \exp(-x\cosh t)\cosh(\nu t)\,dt \qquad (x > 0),$$

$$K_\nu(x) = \frac{1}{\cos\left(\frac{1}{2}\pi\nu\right)} \int_0^\infty \cos(x\sinh t)\cosh(\nu t)\,dt \qquad (x > 0,\ -1 < \nu < 1),$$

$$K_\nu(x) = \frac{1}{\sin\left(\frac{1}{2}\pi\nu\right)} \int_0^\infty \sin(x\sinh t)\sinh(\nu t)\,dt \qquad (x > 0,\ -1 < \nu < 1).$$

For integer $\nu = n$,

$$I_n(x) = \frac{1}{\pi}\int_0^\pi \exp(x\cos t)\cos(nt)\,dt \qquad (n = 0, 1, 2, \dots),$$
$$K_0(x) = \int_0^\infty \cos(x\sinh t)\,dt = \int_0^\infty \frac{\cos(xt)}{\sqrt{t^2+1}}\,dt \qquad (x > 0).$$

► **Asymptotic expansions as $x \to \infty$:**

$$I_\nu(x) = \frac{e^x}{\sqrt{2\pi x}}\left\{1 + \sum_{m=1}^{M}(-1)^m \frac{(4\nu^2-1)(4\nu^2-3^2)\dots[4\nu^2-(2m-1)^2]}{m!\,(8x)^m}\right\},$$
$$K_\nu(x) = \sqrt{\frac{\pi}{2x}}\,e^{-x}\left\{1 + \sum_{m=1}^{M} \frac{(4\nu^2-1)(4\nu^2-3^2)\dots[4\nu^2-(2m-1)^2]}{m!\,(8x)^m}\right\}.$$

The terms of the order of $O(x^{-M-1})$ are omitted in the braces.

M13.8. Degenerate Hypergeometric Functions (Kummer Functions)

M13.8.1. Definitions and Basic Formulas

► **Degenerate hypergeometric functions $\Phi(a, b; x)$ and $\Psi(a, b; x)$.** The *degenerate hypergeometric functions* (*Kummer functions*) $\Phi(a, b; x)$ and $\Psi(a, b; x)$ are solutions of the degenerate hypergeometric equation

$$xy''_{xx} + (b - x)y'_x - ay = 0.$$

In the case $b \neq 0, -1, -2, -3, \dots$, the function $\Phi(a, b; x)$ can be represented as Kummer's series:

$$\Phi(a, b; x) = 1 + \sum_{k=1}^{\infty} \frac{(a)_k}{(b)_k}\frac{x^k}{k!},$$

where $(a)_k = a(a+1)\dots(a+k-1)$, $(a)_0 = 1$.

Table M13.1 presents some special cases where Φ can be expressed in terms of simpler functions.

The function $\Psi(a, b; x)$ is defined as follows:

$$\Psi(a, b; x) = \frac{\Gamma(1-b)}{\Gamma(a-b+1)}\Phi(a, b; x) + \frac{\Gamma(b-1)}{\Gamma(a)}x^{1-b}\Phi(a-b+1,\ 2-b;\ x).$$

Table M13.2 presents some special cases where Ψ can be expressed in terms of simpler functions.

► **Kummer transformation and linear relations.** Kummer transformation:

$$\Phi(a, b; x) = e^x\Phi(b-a, b; -x), \qquad \Psi(a, b; x) = x^{1-b}\Psi(1+a-b, 2-b; x).$$

TABLE M13.1
Special cases of the Kummer function $\Phi(a,b;z)$.

a	b	z	Φ	Notation used
a	a	x	e^x

► **Differentiation formulas and Wronskian.** Differentiation formulas:

$$\frac{d}{dx}\Phi(a,b;x)=\frac{a}{b}\Phi(a+1,b+1;x),\qquad \frac{d^n}{dx^n}\Phi(a,b;x)=\frac{(a)_n}{(b)_n}\Phi(a+n,b+n;x),$$

$$\frac{d}{dx}\Psi(a,b;x)=-a\Psi(a+1,b+1;x),\qquad \frac{d^n}{dx^n}\Psi(a,b;x)=(-1)^n(a)_n\Psi(a+n,b+n;x).$$

Wronskian:

$$W(\Phi,\Psi)=\Phi\Psi'_x-\Phi'_x\Psi=-\frac{\Gamma(b)}{\Gamma(a)}x^{-b}e^x.$$

► **Degenerate hypergeometric functions for $n=0,1,2,\dots$**

$$\Psi(a,n+1;x)=\frac{(-1)^{n-1}}{n!\,\Gamma(a-n)}\biggl\{\Phi(a,n+1;x)\ln x$$
$$+\sum_{r=0}^\infty\frac{(a)_r}{(n+1)_r}\bigl[\psi(a+r)-\psi(1+r)-\psi(1+n+r)\bigr]\frac{x^r}{r!}\biggr\}+\frac{(n-1)!}{\Gamma(a)}\sum_{r=0}^{n-1}\frac{(a-n)_r}{(1-n)_r}\frac{x^{r-n}}{r!},$$

where $n=0,1,2,\dots$ (the last sum is omitted for $n=0$), $\psi(z)=[\ln\Gamma(z)]'_z$ is the logarithmic derivative of the gamma function,

$$\psi(1)=-\mathcal{C},\qquad \psi(n)=-\mathcal{C}+\sum_{k=1}^{n-1}k^{-1},$$

where $\mathcal{C}=0.5772\dots$ is the Euler constant.

If $b < 0$, then the formula

$$\Psi(a, b; x) = x^{1-b}\Psi(a - b + 1,\ 2 - b;\ x)$$

is valid for any x.

For $b \neq 0, -1, -2, -3, \ldots$, the general solution of the degenerate hypergeometric equation can be represented in the form

$$y = C_1\Phi(a, b; x) + C_2\Psi(a, b; x),$$

and for $b = 0, -1, -2, -3, \ldots$, in the form

$$y = x^{1-b}\big[C_1\Phi(a - b + 1,\ 2 - b;\ x) + C_2\Psi(a - b + 1,\ 2 - b;\ x)\big].$$

M13.8.2. Integral Representations and Asymptotic Expansions

► **Integral representations.**

$$\begin{aligned}
\Phi(a, b; x) &= \frac{\Gamma(b)}{\Gamma(a)\,\Gamma(b - a)} \int_0^1 e^{xt} t^{a-1}(1 - t)^{b-a-1}\,dt \quad (\text{for } b > a > 0),\\
\Psi(a, b; x) &= \frac{1}{\Gamma(a)} \int_0^\infty e^{-xt} t^{a-1}(1 + t)^{b-a-1}\,dt \quad (\text{for } a > 0,\ x > 0),
\end{aligned}$$

where $\Gamma(a)$ is the gamma function.

► **Asymptotic expansion as $|x| \to \infty$.**

$$\begin{aligned}
\Phi(a, b; x) &= \frac{\Gamma(b)}{\Gamma(a)} e^x x^{a-b} \left[\sum_{n=0}^{N} \frac{(b - a)_n(1 - a)_n}{n!} x^{-n} + \varepsilon\right], \quad x > 0,\\
\Phi(a, b; x) &= \frac{\Gamma(b)}{\Gamma(b - a)} (-x)^{-a} \left[\sum_{n=0}^{N} \frac{(a)_n(a - b + 1)_n}{n!} (-x)^{-n} + \varepsilon\right], \quad x < 0,\\
\Psi(a, b; x) &= x^{-a} \left[\sum_{n=0}^{N} (-1)^n \frac{(a)_n(a - b + 1)_n}{n!} x^{-n} + \varepsilon\right], \quad -\infty < x < \infty,
\end{aligned}$$

where $\varepsilon = O(x^{-N-1})$.

M13.9. Elliptic Integrals

M13.9.1. Complete Elliptic Integrals

► **Definitions. Properties. Conversion formulas.** *Complete elliptic integral of the first kind*:

$$\mathsf{K}(k) = \int_0^{\pi/2} \frac{d\alpha}{\sqrt{1 - k^2 \sin^2\alpha}} = \int_0^1 \frac{dx}{\sqrt{(1 - x^2)(1 - k^2x^2)}}.$$

Complete elliptic integral of the second kind:

$$\mathsf{E}(k) = \int_0^{\pi/2} \sqrt{1 - k^2 \sin^2\alpha}\,d\alpha = \int_0^1 \frac{\sqrt{1 - k^2x^2}}{\sqrt{1 - x^2}}\,dx.$$

The argument k is called the *elliptic modulus* ($k^2 < 1$).

Notation:

$$k' = \sqrt{1-k^2}, \qquad \mathsf{K}'(k) = \mathsf{K}(k'), \qquad \mathsf{E}'(k) = \mathsf{E}(k'),$$

where k' is the *complementary modulus*.

Properties:

$$\begin{aligned}
&\mathsf{K}(-k) = \mathsf{K}(k), \qquad \mathsf{E}(-k) = \mathsf{E}(k);\\
&\mathsf{K}(k) = \mathsf{K}'(k'), \qquad \mathsf{E}(k) = \mathsf{E}'(k');\\
&\mathsf{E}(k)\,\mathsf{K}'(k) + \mathsf{E}'(k)\,\mathsf{K}(k) - \mathsf{K}(k)\,\mathsf{K}'(k) = \frac{\pi}{2}.
\end{aligned}$$

Conversion formulas for complete elliptic integrals:

$$\begin{aligned}
\mathsf{K}\left(\frac{1-k'}{1+k'}\right) &= \frac{1+k'}{2}\,\mathsf{K}(k),\\
\mathsf{E}\left(\frac{1-k'}{1+k'}\right) &= \frac{1}{1+k'}\big[\mathsf{E}(k) + k'\,\mathsf{K}(k)\big],\\
\mathsf{K}\left(\frac{2\sqrt{k}}{1+k}\right) &= (1+k)\,\mathsf{K}(k),\\
\mathsf{E}\left(\frac{2\sqrt{k}}{1+k}\right) &= \frac{1}{1+k}\big[2\,\mathsf{E}(k) - (k')^2\,\mathsf{K}(k)\big].
\end{aligned}$$

► **Representation of complete elliptic integrals in series form.** Representation of complete elliptic integrals in the form of series in powers of the modulus k:

$$\begin{aligned}
\mathsf{K}(k) &= \frac{\pi}{2}\left\{1 + \left(\frac{1}{2}\right)^2 k^2 + \left(\frac{1\times 3}{2\times 4}\right)^2 k^4 + \cdots + \left[\frac{(2n-1)!!}{(2n)!!}\right]^2 k^{2n} + \cdots\right\},\\
\mathsf{E}(k) &= \frac{\pi}{2}\left\{1 - \left(\frac{1}{2}\right)^2 \frac{k^2}{1} - \left(\frac{1\times 3}{2\times 4}\right)^2 \frac{k^4}{3} - \cdots - \left[\frac{(2n-1)!!}{(2n)!!}\right]^2 \frac{k^{2n}}{2n-1} - \cdots\right\}.
\end{aligned}$$

► **Differentiation formulas. Differential equations.** Differentiation formulas:

$$\frac{d\,\mathsf{K}(k)}{dk} = \frac{\mathsf{E}(k)}{k(k')^2} - \frac{\mathsf{K}(k)}{k}, \qquad \frac{d\,\mathsf{E}(k)}{dk} = \frac{\mathsf{E}(k) - \mathsf{K}(k)}{k}.$$

The functions $\mathsf{K}(k)$ and $\mathsf{K}'(k)$ satisfy the second-order linear ordinary differential equation

$$\frac{d}{dk}\left[k(1-k^2)\frac{d\,\mathsf{K}}{dk}\right] - k\,\mathsf{K} = 0.$$

The functions $\mathsf{E}(k)$ and $\mathsf{E}'(k) - \mathsf{K}'(k)$ satisfy the second-order linear ordinary differential equation

$$(1-k^2)\frac{d}{dk}\left(k\frac{d\,\mathsf{E}}{dk}\right) + k\,\mathsf{E} = 0.$$

M13.9.2. Incomplete Elliptic Integrals

► **Definitions. Properties.** *Elliptic integral of the first kind*:

$$F(\varphi,k)=\int_0^{\varphi}\frac{d\alpha}{\sqrt{1-k^2\sin^2\alpha}}=\int_0^{\sin\varphi}\frac{dx}{\sqrt{(1-x^2)(1-k^2x^2)}}.$$

Elliptic integral of the second kind:

$$E(\varphi,k)=\int_0^{\varphi}\sqrt{1-k^2\sin^2\alpha}\,d\alpha=\int_0^{\sin\varphi}\frac{\sqrt{1-k^2x^2}}{\sqrt{1-x^2}}\,dx.$$

Elliptic integral of the third kind:

$$\Pi(\varphi,n,k)=\int_0^{\varphi}\frac{d\alpha}{(1-n\sin^2\alpha)\sqrt{1-k^2\sin^2\alpha}}=\int_0^{\sin\varphi}\frac{dx}{(1-nx^2)\sqrt{(1-x^2)(1-k^2x^2)}}.$$

The quantity k is called the *elliptic modulus* ($k^2<1$), $k'=\sqrt{1-k^2}$ is the *complementary modulus*, and n is the *characteristic parameter*.

Complete elliptic integrals:

$$\mathsf{K}(k)=F\Big(\frac{\pi}{2},k\Big),\qquad \mathsf{E}(k)=E\Big(\frac{\pi}{2},k\Big),$$
$$\mathsf{K}'(k)=F\Big(\frac{\pi}{2},k'\Big),\qquad \mathsf{E}'(k)=E\Big(\frac{\pi}{2},k'\Big).$$

Properties of elliptic integrals:

$$F(-\varphi,k)=-F(\varphi,k),\qquad F(n\pi\pm\varphi,k)=2n\,\mathsf{K}(k)\pm F(\varphi,k);$$
$$E(-\varphi,k)=-E(\varphi,k),\qquad E(n\pi\pm\varphi,k)=2n\,\mathsf{E}(k)\pm E(\varphi,k).$$

► **Conversion formulas.** Conversion formulas for elliptic integrals (first set):

$$F\left(\psi,\frac{1}{k}\right)=kF(\varphi,k),$$
$$E\left(\psi,\frac{1}{k}\right)=\frac{1}{k}\big[E(\varphi,k)-(k')^2F(\varphi,k)\big],$$

where the arguments φ and ψ, which may be treated as angles, are related by $\sin\psi=k\sin\varphi$, $\cos\psi=\sqrt{1-k^2\sin^2\varphi}$.

Conversion formulas for elliptic integrals (second set):

$$F\left(\psi,\frac{1-k'}{1+k'}\right)=(1+k')F(\varphi,k),$$
$$E\left(\psi,\frac{1-k'}{1+k'}\right)=\frac{2}{1+k'}\big[E(\varphi,k)+k'F(\varphi,k)\big]-\frac{1-k'}{1+k'}\sin\psi,$$

where φ and ψ are related by $\tan(\psi-\varphi)=k'\tan\varphi$.

Transformation formulas for elliptic integrals (third set):

$$F\left(\psi,\frac{2\sqrt{k}}{1+k}\right)=(1+k)F(\varphi,k),$$
$$E\left(\psi,\frac{2\sqrt{k}}{1+k}\right)=\frac{1}{1+k}\left[2E(\varphi,k)-(k')^2F(\varphi,k)+2k\frac{\sin\varphi\,\cos\varphi}{1+k\sin^2\varphi}\sqrt{1-k^2\sin^2\varphi}\right],$$

where φ and ψ are related by $\sin\psi=\dfrac{(1+k)\sin\varphi}{1+k\sin^2\varphi}$.

M13.10. Orthogonal Polynomials

All zeros of each of the orthogonal polynomials $\mathcal{P}_n(x)$ considered in this section are real and simple. The zeros of the polynomials $\mathcal{P}_n(x)$ and $\mathcal{P}_{n+1}(x)$ are alternating.

M13.10.1. Legendre Polynomials and Legendre Functions

► **Explicit and recurrence formulas for Legendre polynomials and functions.** The *Legendre polynomials* $P_n(x)$ and the *Legendre functions* $Q_n(x)$ are solutions of the second-order linear ordinary differential equation

$$(1-x^2)y''_{xx} - 2xy'_x + n(n+1)y = 0.$$

The *Legendre polynomials* $P_n(x)$ and the Legendre functions $Q_n(x)$ are defined by the formulas

$$P_n(x) = \frac{1}{n!\,2^n}\frac{d^n}{dx^n}(x^2-1)^n,$$
$$Q_n(x) = \frac{1}{2}P_n(x)\ln\frac{1+x}{1-x} - \sum_{m=1}^{n}\frac{1}{m}P_{m-1}(x)P_{n-m}(x).$$

The polynomials $P_n(x)$ can be calculated using the formulas

$$P_0(x) = 1, \quad P_1(x) = x, \quad P_2(x) = \frac{1}{2}(3x^2-1),$$
$$P_3(x) = \frac{1}{2}(5x^3-3x), \quad P_4(x) = \frac{1}{8}(35x^4-30x^2+3),$$
$$P_{n+1}(x) = \frac{2n+1}{n+1}xP_n(x) - \frac{n}{n+1}P_{n-1}(x).$$

The first five functions $Q_n(x)$ have the form

$$Q_0(x) = \frac{1}{2}\ln\frac{1+x}{1-x}, \quad Q_1(x) = \frac{x}{2}\ln\frac{1+x}{1-x} - 1,$$
$$Q_2(x) = \frac{1}{4}(3x^2-1)\ln\frac{1+x}{1-x} - \frac{3}{2}x, \quad Q_3(x) = \frac{1}{4}(5x^3-3x)\ln\frac{1+x}{1-x} - \frac{5}{2}x^2 + \frac{2}{3},$$
$$Q_4(x) = \frac{1}{16}(35x^4-30x^2+3)\ln\frac{1+x}{1-x} - \frac{35}{8}x^3 + \frac{55}{24}x.$$

The polynomials $P_n(x)$ have the explicit representation

$$P_n(x) = 2^{-n}\sum_{m=0}^{[n/2]}(-1)^m C_n^m C_{2n-2m}^n x^{n-2m},$$

where $[A]$ stands for the integer part of a number A.

► **Zeros and orthogonality of the Legendre polynomials.** The polynomials $P_n(x)$ (with natural n) have exactly n real distinct zeros; all zeros lie on the interval $-1 < x < 1$. The zeros of $P_n(x)$ and $P_{n+1}(x)$ alternate with each other. The function $Q_n(x)$ has exactly $n+1$ zeros, which lie on the interval $-1 < x < 1$.

The functions $P_n(x)$ form an orthogonal system on the interval $-1 \le x \le 1$, with

$$\int_{-1}^{1} P_n(x)P_m(x)\,dx = \begin{cases} 0 & \text{if } n \neq m, \\ \dfrac{2}{2n+1} & \text{if } n = m. \end{cases}$$

► **Generating functions.** The generating function for Legendre polynomials is

$$\frac{1}{\sqrt{1-2sx+s^2}} = \sum_{n=0}^{\infty} P_n(x)s^n \qquad (|s| < 1).$$

The generating function for Legendre functions is

$$\frac{1}{\sqrt{1-2sx+s^2}} \ln\left[\frac{x-s+\sqrt{1-2sx+s^2}}{\sqrt{1-x^2}}\right] = \sum_{n=0}^{\infty} Q_n(x)s^n \qquad (|s| < 1,\ x > 1).$$

► **Associated Legendre functions with integer indices. Differential equation.** The *associated Legendre functions* $P_n^m(x)$ of order m are defined by the formulas

$$P_n^m(x) = (1-x^2)^{m/2}\frac{d^m}{dx^m}P_n(x), \qquad n = 1,\ 2,\ 3,\ \dots, \quad m = 0,\ 1,\ 2,\ \dots$$

It is assumed by definition that $P_n^0(x) = P_n(x)$.

Properties:

$$P_n^m(x) = 0 \quad \text{if} \quad m > n, \qquad P_n^m(-x) = (-1)^{n-m}P_n^m(x).$$

The associated Legendre functions $P_n^m(x)$ have exactly $n-m$ distinct real zeros, all of which lie on the interval $-1 < x < 1$.

Some of the associated Legendre functions $P_n^m(x)$ with lower indices are

$$P_1^1(x) = (1-x^2)^{1/2}, \quad P_2^1(x) = 3x(1-x^2)^{1/2}, \quad P_2^2(x) = 3(1-x^2),$$
$$P_3^1(x) = \tfrac{3}{2}(5x^2-1)(1-x^2)^{1/2}, \quad P_3^2(x) = 15x(1-x^2), \quad P_3^3(x) = 15(1-x^2)^{3/2}.$$

The associated Legendre functions $P_n^m(x)$ with $n > m$ are solutions of the linear ordinary differential equation

$$(1-x^2)y''_{xx} - 2xy'_x + \left[n(n+1) - \frac{m^2}{1-x^2}\right]y = 0.$$

► **Orthogonality of the associated Legendre functions.** The functions $P_n^m(x)$ form an orthogonal system on the interval $-1 \le x \le 1$, with

$$\int_{-1}^{1} P_n^m(x)P_k^m(x)\,dx = \begin{cases} 0 & \text{if } n \neq k, \\ \dfrac{2}{2n+1}\dfrac{(n+m)!}{(n-m)!} & \text{if } n = k. \end{cases}$$

The functions $P_n^m(x)$ (with $m \neq 0$) are orthogonal on the interval $-1 \le x \le 1$ with weight $(1-x^2)^{-1}$, that is,

$$\int_{-1}^{1} \frac{P_n^m(x)P_n^k(x)}{1-x^2}\,dx = \begin{cases} 0 & \text{if } m \neq k, \\ \dfrac{(n+m)!}{m(n-m)!} & \text{if } m = k. \end{cases}$$

M13.10.2. Laguerre Polynomials and Generalized Laguerre Polynomials

► **Laguerre polynomials.** The Laguerre polynomials $L_n(x)$ satisfy the second-order linear ordinary differential equation

$$xy''_{xx} + (1-x)y'_x + ny = 0$$

and are defined by the formulas

$$L_n(x) = \frac{1}{n!}e^x \frac{d^n}{dx^n}\big(x^n e^{-x}\big) = \frac{(-1)^n}{n!}\left[x^n - n^2 x^{n-1} + \frac{n^2(n-1)^2}{2!}x^{n-2} + \cdots\right].$$

The first four polynomials have the form

$$L_0(x) = 1, \quad L_1(x) = -x+1, \quad L_2(x) = \tfrac{1}{2}(x^2-4x+2), \quad L_3(x) = \tfrac{1}{6}(-x^3+9x^2-18x+6).$$

To calculate $L_n(x)$ for $n \ge 2$, one can use the recurrence formulas

$$L_{n+1}(x) = \frac{1}{n+1}\big[(2n+1-x)L_n(x) - nL_{n-1}(x)\big].$$

The functions $L_n(x)$ form an orthonormal system on the interval $0 < x < \infty$ with weight e^{-x}:

$$\int_0^\infty e^{-x} L_n(x) L_m(x)\,dx = \begin{cases} 0 & \text{if } n \ne m, \\ 1 & \text{if } n = m. \end{cases}$$

The generating function is

$$\frac{1}{1-s}\exp\Big(-\frac{sx}{1-s}\Big) = \sum_{n=0}^\infty L_n(x)s^n, \qquad |s| < 1.$$

► **Generalized Laguerre polynomials.** The generalized Laguerre polynomials $L_n^\alpha(x)$ $(\alpha > -1)$ satisfy the equation

$$xy''_{xx} + (\alpha+1-x)y'_x + ny = 0$$

and are defined by the formulas

$$L_n^\alpha(x) = \frac{1}{n!}x^{-\alpha}e^x\frac{d^n}{dx^n}\big(x^{n+\alpha}e^{-x}\big) = \sum_{m=0}^n C_{n+\alpha}^{n-m}\frac{(-x)^m}{m!} = \sum_{m=0}^n \frac{\Gamma(n+\alpha+1)}{\Gamma(m+\alpha+1)}\,\frac{(-x)^m}{m!\,(n-m)!}.$$

Notation: $L_n^0(x) = L_n(x)$.
Special cases:

$$L_0^\alpha(x) = 1, \quad L_1^\alpha(x) = \alpha+1-x, \quad L_n^{-n}(x) = (-1)^n\frac{x^n}{n!}.$$

To calculate $L_n^\alpha(x)$ for $n \ge 2$, one can use the recurrence formulas

$$L_{n+1}^\alpha(x) = \frac{1}{n+1}\big[(2n+\alpha+1-x)L_n^\alpha(x) - (n+\alpha)L_{n-1}^\alpha(x)\big].$$

Other recurrence formulas:

$$L_n^\alpha(x)=L_{n-1}^\alpha(x)+L_n^{\alpha-1}(x),\quad \frac{d}{dx}L_n^\alpha(x)=-L_{n-1}^{\alpha+1}(x),\quad x\frac{d}{dx}L_n^\alpha(x)=nL_n^\alpha(x)-(n+\alpha)L_{n-1}^\alpha(x).$$

The functions $L_n^\alpha(x)$ form an orthogonal system on the interval $0 < x < \infty$ with weight $x^\alpha e^{-x}$:

$$\int_0^\infty x^\alpha e^{-x} L_n^\alpha(x) L_m^\alpha(x)\,dx = \begin{cases} 0 & \text{if } n \neq m, \\ \frac{\Gamma(\alpha+n+1)}{n!} & \text{if } n = m. \end{cases}$$

The generating function is

$$(1-s)^{-\alpha-1}\exp\Bigl(-\frac{sx}{1-s}\Bigr) = \sum_{n=0}^\infty L_n^\alpha(x)s^n, \qquad |s| < 1.$$

M13.10.3. Chebyshev Polynomials

► **Chebyshev polynomials of the first kind.** The *Chebyshev polynomials of the first kind* $T_n(x)$ satisfy the second-order linear ordinary differential equation

$$(1-x^2)y''_{xx} - xy'_x + n^2y = 0$$

and are defined by the formulas

$$\begin{aligned} T_n(x) = \cos(n \arccos x) &= \frac{(-2)^n n!}{(2n)!}\sqrt{1-x^2}\,\frac{d^n}{dx^n}\bigl[(1-x^2)^{n-\frac12}\bigr] \\ &= \frac{n}{2}\sum_{m=0}^{[n/2]}(-1)^m\frac{(n-m-1)!}{m!\,(n-2m)!}(2x)^{n-2m} \qquad (n = 0, 1, 2, \dots), \end{aligned}$$

where $[A]$ stands for the integer part of a number A.

An alternative representation of the Chebyshev polynomials:

$$T_n(x) = \frac{(-1)^n}{(2n-1)!!}(1-x^2)^{1/2}\frac{d^n}{dx^n}(1-x^2)^{n-1/2}.$$

The first five Chebyshev polynomials of the first kind are

$$T_0(x) = 1,\quad T_1(x) = x,\quad T_2(x) = 2x^2 - 1,\quad T_3(x) = 4x^3 - 3x,\quad T_4(x) = 8x^4 - 8x^2 + 1.$$

The recurrence formulas:

$$T_{n+1}(x) = 2xT_n(x) - T_{n-1}(x), \qquad n \geq 2.$$

The functions $T_n(x)$ form an orthogonal system on the interval $-1 < x < 1$ with weight $(1-x^2)^{-1/2}$:

$$\int_{-1}^1 \frac{T_n(x)T_m(x)}{\sqrt{1-x^2}}\,dx = \begin{cases} 0 & \text{if } n \neq m, \\ \frac12\pi & \text{if } n = m \neq 0, \\ \pi & \text{if } n = m = 0. \end{cases}$$

The generating function is

$$\frac{1-sx}{1-2sx+s^2} = \sum_{n=0}^\infty T_n(x)s^n \qquad (|s| < 1).$$

The functions $T_n(x)$ have only real simple zeros, all lying on the interval $-1 < x < 1$.

The normalized Chebyshev polynomials of the first kind, $2^{1-n}T_n(x)$, deviate from zero least of all. This means that among all polynomials of degree n with the leading coefficient 1, the maximum of the modulus $\max\limits_{-1\leq x\leq 1}|2^{1-n}T_n(x)|$ has the least value, with the maximum being equal to 2^{1-n}.

► **Chebyshev polynomials of the second kind.** The *Chebyshev polynomials of the second kind* $U_n(x)$ satisfy the second-order linear ordinary differential equation

$$(1-x^2)y''_{xx} - 3xy'_x + n(n+2)y = 0$$

and are defined by the formulas

$$U_n(x) = \frac{\sin[(n+1)\arccos x]}{\sqrt{1-x^2}} = \frac{2^n(n+1)!}{(2n+1)!}\frac{1}{\sqrt{1-x^2}}\frac{d^n}{dx^n}(1-x^2)^{n+1/2}$$
$$= \sum_{m=0}^{[n/2]}(-1)^m\frac{(n-m)!}{m!\,(n-2m)!}(2x)^{n-2m} \qquad (n=0,\ 1,\ 2,\ \ldots).$$

The first five Chebyshev polynomials of the second kind are

$U_0(x)=1,\quad U_1(x)=2x,\quad U_2(x)=4x^2-1,\quad U_3(x)=8x^3-4x,\quad U_4(x)=16x^4-12x^2+1.$

The recurrence formulas:

$$U_{n+1}(x) = 2xU_n(x) - U_{n-1}(x), \qquad n \ge 2.$$

The generating function is

$$\frac{1}{1-2sx+s^2} = \sum_{n=0}^{\infty} U_n(x)s^n \qquad (|s|<1).$$

The Chebyshev polynomials of the first and second kinds are related by

$$U_n(x) = \frac{1}{n+1}\frac{d}{dx}T_{n+1}(x).$$

M13.10.4. Hermite Polynomials

► **Various representations of the Hermite polynomials.** The *Hermite polynomials* $H_n(x)$ satisfy the second-order linear ordinary differential equation

$$y''_{xx} - 2xy'_x + 2ny = 0$$

and are defined by the formulas

$$H_n(x) = (-1)^n\exp\bigl(x^2\bigr)\frac{d^n}{dx^n}\exp\bigl(-x^2\bigr) = \sum_{m=0}^{[n/2]}(-1)^m\frac{n!}{m!\,(n-2m)!}(2x)^{n-2m}.$$

The first five polynomials are

$H_0(x)=1,\quad H_1(x)=2x,\quad H_2(x)=4x^2-2,\quad H_3(x)=8x^3-12x,\quad H_4(x)=16x^4-48x^2+12.$

Recurrence formulas:

$$H_{n+1}(x) = 2xH_n(x) - 2nH_{n-1}(x), \qquad n \ge 2;$$
$$\frac{d}{dx}H_n(x) = 2nH_{n-1}(x).$$

Integral representation:

$$H_{2n}(x) = \frac{(-1)^n 2^{2n+1}}{\sqrt{\pi}}\exp\bigl(x^2\bigr)\int_0^\infty \exp\bigl(-t^2\bigr)t^{2n}\cos(2xt)\,dt,$$
$$H_{2n+1}(x) = \frac{(-1)^n 2^{2n+2}}{\sqrt{\pi}}\exp\bigl(x^2\bigr)\int_0^\infty \exp\bigl(-t^2\bigr)t^{2n+1}\sin(2xt)\,dt,$$

where $n=0,\ 1,\ 2,\ \ldots$

► **Orthogonality. The generating function. An asymptotic formula.** The functions $H_n(x)$ form an orthogonal system on the interval $-\infty < x < \infty$ with weight e^{-x^2}:

$$\int_{-\infty}^{\infty} \exp\bigl(-x^2\bigr) H_n(x) H_m(x)\,dx = \begin{cases} 0 & \text{if } n \neq m, \\ \sqrt{\pi}\,2^n n! & \text{if } n = m. \end{cases}$$

Generating function:

$$\exp\bigl(-s^2 + 2sx\bigr) = \sum_{n=0}^{\infty} H_n(x) \frac{s^n}{n!}.$$

Asymptotic behavior as $n \to \infty$:

$$H_n(x) \approx 2^{\frac{n+1}{2}} n^{\frac{n}{2}} e^{-\frac{n}{2}} \exp\bigl(x^2\bigr) \cos\bigl(\sqrt{2n+1}\,x - \tfrac{1}{2}\pi n\bigr).$$

► **Hermite functions.** The *Hermite functions* $h_n(x)$ are introduced by the formula

$$h_n(x) = \exp\Bigl(-\frac{1}{2}x^2\Bigr) H_n(x) = (-1)^n \exp\Bigl(\frac{1}{2}x^2\Bigr) \frac{d^n}{dx^n} \exp\bigl(-x^2\bigr), \qquad n = 0, 1, 2, \ldots$$

The Hermite functions satisfy the second-order linear ordinary differential equation

$$h''_{xx} + (2n + 1 - x^2)h = 0.$$

The functions $h_n(x)$ form an orthogonal system on the interval $-\infty < x < \infty$:

$$\int_{-\infty}^{\infty} h_n(x) h_m(x)\,dx = \begin{cases} 0 & \text{if } n \neq m, \\ \sqrt{\pi}\,2^n n! & \text{if } n = m. \end{cases}$$

Chapter M14

Probability Theory

M14.1. Basic Concepts and Simplest Probabilistic Models

M14.1.1. Rules and Formulas of Combinatorics

Below are rules and formulas of combinatorics that are useful in solving problems of probability theory.

► **Rule of sum and rule of product.**

Rule of sum. Suppose there is a collection of objects (of arbitrary nature). If an object α can be chosen from this collection in m different ways and another object β can be chosen in k ways, then one can choose *either object α or object β* in $m+k$ different ways.

Rule of product. If an object α can be chosen in m ways and after that an object β can be chosen in k ways, then one can choose the *ordered pair of objects* (α, β) in mk ways.

Example 1. How many two-digit numbers are there consisting of different digits?

The first digit can be one of 1, 2, ..., 9 and the other, one of the eight remaining plus 0 (i.e., one of nine digits). So, by the rule of product, there are $9\times 9 = 81$ two-digit numbers consisting of different digits.

► **Permutations and combinations.**

Given a set of n (distinct) elements, an arrangement of r elements from this set ($r \le n$) taken in a certain order is called a *permutation*. The total number of different permutations is equal to

$$P_n^r = n(n-1)(n-2)\dots(n-r+1) = \frac{n!}{(n-r)!},$$

which is also denoted $P_r^n = {}_nP_r = P(n,r)$.

Example 2. How many three-digit numbers can be made up from the six digits 0, 1, 2, 3, 4, 5 without repetitions?

Three out of the six digits (in a certain order) can be selected in P_6^3 ways. The triplets that start with 0 (i.e., the number of two-digit numbers consisting of 1, ..., 5) must be subtracted from this. So the desired number of three-digit numbers is $P_6^3 - P_5^2 = 6\cdot 5\cdot 4 - 5\cdot 4 = 100$.

Note that the number of different permutations on a set of n elements (i.e., arrangements that differ from each other by only the order of selection of the n elements) is equal to

$$P_n^n = n! = 1\cdot 2\cdot 3\dots n.$$

Note that $0! = 1$.

Example 3. How many ways can four people be seated at a table?

This can be done in $P_4^4 = 4! = 1\cdot 2\cdot 3\cdot 4 = 24$ ways.

An arrangement of r elements selected from a set of n elements where the order is not important is called a *combination*. The number of combinations is equal to

$$C_n^r = \frac{P_n^r}{P_r^r} = \frac{n(n-1)(n-2)\dots(n-r+1)}{r!} = \frac{n!}{r!\,(n-r)!}$$

and is also denoted $C_r^n = {}_nC_r = C(n,r) = \binom{n}{r}$. Note that the relation $C_n^r = C_n^{n-r}$ holds.

Example 4. How many ways can three balls be selected from a box containing six numbered balls?

The desired number equals the number of combinations of three elements from a set of six elements, or $C_6^3 = \dfrac{6 \cdot 5 \cdot 4}{3 \cdot 2 \cdot 1} = 20$.

M14.1.2. Probabilities of Random Events

► **Random events. Basic definitions.** The simplest mutually exclusive outcomes of an experiment are called *elementary events* ω_i. The set of all elementary outcomes, which we denote by the symbol Ω, is called the *space of elementary events* (or the *sample space*). Any subset of Ω is called a *random event* A (or simply an *event* A). Event A is said to occur when the outcome of the experiment is one of the elementary events that make up A.

Example 1. Suppose the experiment is rolling a six-sided die once. There are six possible mutually exclusive outcomes and the space of elementary events is $\Omega = \{\omega_1, \omega_2, \omega_3, \omega_4, \omega_5, \omega_6\}$, where elementary event ω_k stands for rolling a k on the die. If event A is rolling an odd number on the die, then A occurs when the outcome is one of the elementary events ω_1, ω_3, ω_5.

An event A *implies* an event B ($A \subseteq B$) if B occurs when A occurs. Events A and B are said to be *equivalent* ($A = B$) if A implies B and B implies A, i.e., if both events A and B occur or do not occur simultaneously.

The *union* $C = A \cup B = A + B$ of events A and B is the event that at least one of the events A or B occurs. The elementary outcomes of the union $A + B$ are the elementary outcomes that belong to at least one of the events A and B.

The *intersection* $C = A \cap B = AB$ of events A and B is the event that both A and B occur. The elementary outcomes of the intersection AB are the elementary outcomes that simultaneously belong to A and B.

The *difference* $C = A \backslash B = A - B$ of events A and B is the event that A occurs and B does not occur. The elementary outcomes of the difference $A \backslash B$ are the elementary outcomes of A that do not belong to B.

The event that A does not occur is called the *complement* of A, or the *complementary event*, and is denoted by $\overline{A}$. The elementary outcomes of $\overline{A}$ are the elementary outcomes that do not belong to event A.

The set Ω is called a *sure event* or a *certain event* (it will always happen). The empty set $\varnothing$ is called an *impossible event* (it will never happen).

Two complementary events A and $\overline{A}$ are said to be *opposite*; they simultaneously satisfy the following two conditions:

$$A \cup \overline{A} = \Omega, \quad A \cap \overline{A} = \varnothing.$$

Events A and B are said to be *incompatible*, or *mutually exclusive*, if their simultaneous realization is impossible, i.e., if $A \cap B = \varnothing$.

Events $H_1, \dots, H_n$ are said to form a *complete group of events*, or to be *collectively exhaustive*, if at least one of them necessarily occurs for each trial of the experiment, i.e., if

$$H_1 \cup \cdots \cup H_n = \Omega.$$

Events $H_1, \dots, H_n$ form a *complete group of mutually exclusive* or *pairwise incompatible events* if exactly one of the events necessarily occurs for each trial of the experiment, i.e., if

$$H_1 \cup \cdots \cup H_n = \Omega \quad \text{and} \quad H_i \cap H_j = \varnothing \quad (i \neq j).$$

Main properties of random events:

1. $A \cup B = B \cup A$ and $A \cap B = B \cap A$ (commutativity).

2. $(A\cup B)\cap C=(A\cap C)\cup(B\cap C)$ and $(A\cap B)\cup C=(A\cup C)\cap(B\cup C)$ (distributivity).
3. $(A\cup B)\cup C=A\cup(B\cup C)$ and $(A\cap B)\cap C=A\cap(B\cap C)$ (associativity).
4. $A\cup A=A$ and $A\cap A=A$.
5. $A\cup\Omega=\Omega$ and $A\cap\Omega=A$.
6. $A\cup\overline{A}=\Omega$ and $A\cap\overline{A}=\varnothing$.
7. $\overline{\varnothing}=\Omega$, $\overline{\Omega}=\varnothing$, and $\overline{\overline{A}}=A$.
8. $A\setminus B=A\cap\overline{B}$.
9. $\overline{A\cup B}=\overline{A}\cap\overline{B}$ and $\overline{A\cap B}=\overline{A}\cup\overline{B}$ (*de Morgan's laws*).

► **Discrete probability space. Classical definition of probability.** Suppose that $\Omega=\{\omega_1,\dots,\omega_n\}$ is a finite sample space. To each elementary event $\omega_i\in\Omega$ $(i=1,2,\dots,n)$ there corresponds a number $p(\omega_i)$, called the probability of the elementary event ω_i. Thus a real function satisfying the following two conditions is defined on the set Ω:

1. *Nonnegativity condition*: $p(\omega_i)\ge 0$ for any $\omega_i\in\Omega$.
2. *Normalization condition*: $\sum_{i=1}^{n} p(\omega_i)=1$.

The *probability* $P(A)$ of an event A for any subset $A\subset\Omega$ is defined to be the sum of the probabilities of the elementary events that form A; i.e.,

$$P(A)=\sum_{\omega_i\in A} p(\omega_i). \tag{M14.1.2.1}$$

Note that the relations $0\le P(A)\le 1$, $P(\varnothing)=0$, and $P(\Omega)=1$ are always valid.

A special case of the definition of probability (M14.1.2.1) is the *classical definition of probability*, in which all elementary events are equally likely: $p(\omega_1)=\dots=p(\omega_n)=1/n$. Then the probability of the event A is

$$P(A)=\frac{m}{n}, \tag{M14.1.2.2}$$

where m is the number of elementary events making up A (the number *favorable* outcomes).

Example 2. In example 1, the probability of rolling an odd number is

$$P(A)=\tfrac{3}{6}=\tfrac{1}{2}.$$

Example 3. Let two dice be rolled. Under the assumption that the elementary events are equiprobable, find the probability of the event A that the sum of the numbers rolled is greater than 10. Obviously, the sample space can be represented as $\Omega=\{(i,j):i,j=1,2,3,4,5,6\}$, where i is the number shown by the first die and j is that shown by the second die. The total number of elementary events is $|\Omega|=36$. Event A is represented by the subset $A=\{(5,6),(6,5),(6,6)\}$ of Ω. Since $|A|=3$, formula (M14.1.2.2) gives $P(A)=|A|/|\Omega|=3/36=1/12$.

► **Statistical definition of probability.** Suppose an experiment has been repeated N times and an event A has occurred k times. The ratio k/N is called the *relative frequency* of the event A in the given series of experiments. The number about which the relative frequency oscillates in long series of experiments is called the probability $P(A)$ of the event A.

► **Geometric definition of probability.** In the geometric approach to defining probability, one takes an arbitrary set on a straight line, in a plane, or in space to be the sample space Ω. A trial of an experiment is interpreted as a random selection of a point in Ω. The occurrence of an event A is treated as the occurrence of the point in a subdomain A of Ω. It is assumed that the probability of selecting a point in the domain A is proportional to the measure of A (i.e., to its length, area, or volume) and is independent of the position and shape of the domain. The probability of the event A is defined as

$$P(A)=\frac{\text{measure }A}{\text{measure }\Omega}.$$

Example 3. A point is randomly dropped inside a circle of radius $R = 1$. Find the probability of the event that the point lands in the circle of radius $r = \frac{1}{2}$ concentric with the larger one.

Let A be the event that the point lands in the smaller circle. We find the probability $P(A)$ as the ratio of the area of the smaller circle to that of the larger one:

$$P(A) = \frac{\pi r^2}{\pi R^2} = \frac{1}{4}.$$

► **Axiomatic definition of probability.** The *probability of an event* is defined to be a single-valued real function $P(A)$ satisfying the following three axioms:

1. *Nonnegativity*: $P(A) \geq 0$ for any $A \in \Omega$.
2. *Normalization*: $P(\Omega) = 1$.
3. *Additivity*: $P\Bigl(\bigcup\limits_n A_n\Bigr) = \sum\limits_n P(A_n)$, provided that $A_i \cap A_j = \varnothing$ whenever $i \neq j$.

Properties of probability:

1. The probability of an impossible event is zero; i.e., $P(\varnothing) = 0$.
2. The probability of the event $\overline{A}$ opposite to an event A is equal to $P(\overline{A}) = 1 - P(A)$.
3. Probability is a bounded function; i.e., $0 \leq P(A) \leq 1$.
4. If an event A implies an event B ($A \subseteq B$), then $P(A) \leq P(B)$.
5. If events $A_1, \ldots, A_n$ form a complete group of pairwise incompatible events, then $\sum\limits_{i=1}^{n} P(A_i) = 1$.

M14.1.3. Conditional Probability. Total Probability Formula

► **Probability of the union of events.** The probability of realization of at least one of two events H_1 and H_2 is given by the formula (addition theorem)

$$P(H_1 \cup H_2) = P(H_1) + P(H_2) - P(H_1 \cap H_2).$$

In particular, for $H_1 \cap H_2 = \varnothing$, we have

$$P(H_1 \cup H_2) = P(H_1) + P(H_2).$$

The probability of realization of at least one of n events is given by the formula

$$\begin{aligned} P(H_1 \cup \cdots \cup H_n) &= \sum_{k=1}^{n} P(H_k) - \sum_{1\leq k_1<k_2\leq n} P(H_{k_1} \cap H_{k_2}) \\ &\quad + \sum_{1\leq k_1<k_2<k_3\leq n} P(H_{k_1} \cap H_{k_2} \cap H_{k_3}) - \cdots + (-1)^{n-1} P(H_1 \cap \cdots \cap H_n). \qquad \text{(M14.1.3.1)} \end{aligned}$$

Note that $P(H_1 \cup H_2)$ is also written $P(H_1 + H_2)$.

For n pairwise incompatible events $H_1, H_2, \ldots, H_n$ ($H_i \cap H_j = \varnothing$ for $i \neq j$), formula (M14.1.3.1) simplifies to become

$$P(H_1 \cup \cdots \cup H_n) = P(H_1) + P(H_2) + \cdots + P(H_n).$$

It may often be convenient to calculate the probability of the sum of events via the probability of the product of opposite events:

$$P(H_1 \cup \cdots \cup H_n) = 1 - P(\bar{H}_1 \cap \bar{H}_2 \cap \cdots \cap \bar{H}_n).$$

► **Conditional probability.** The *conditional probability* $P(A|H)$ of an event A given the occurrence of some other event H is defined by the formula

$$P(A|H) = \frac{P(A \cap H)}{P(H)}, \quad P(H) > 0. \qquad \text{(M14.1.3.2)}$$

Relation (M14.1.3.2) can be rewritten (multiplication theorem)

$$P(A \cap H) = P(H)\, P(A|H). \qquad \text{(M14.1.3.3)}$$

The probability $P(A \cap H)$ is also written $P(AH)$.

The formula

$$P(A_1 \cap \cdots \cap A_n) = P(A_1)\, P(A_2|A_1)\, P(A_3|A_1 \cap A_2) \ldots P(A_n|A_1 \cap \cdots \cap A_{n-1})$$

is a generalization of (M14.1.3.3).

Example 1. Two guns shoot one and the same target independently, once each. The probability for the first gun to hit the target is 0.8 and that for the second gun is 0.9. It is required to find:

a) the probability that the target is hit only once and

b) the probability that the target is hit at least once.

a) Let A and B denote the events that the first and second guns hit the target, respectively. Then the probability that the target is hit only once is $P(A\bar{B} + \bar{A}B) = P(A\bar{B}) + P(\bar{A}B) = P(A)P(\bar{B}) + P(\bar{A})P(B) = 0.8\,(1 - 0.9) + (1 - 0.8)\,0.9 = 0.26$.

b) The probability of at least one hit is $P(A+B) = P(A) + P(B) - P(A)P(B) = 0.8 + 0.9 - 0.8 \cdot 0.9 = 0.98$. Note that this result is usually obtained as follows: $P(A+B) = 1 - P(\bar{A}\bar{B}) = 1 - P(\bar{A})P(\bar{B}) = 1 - 0.2 \cdot 0.1 = 0.98$.

► **Independence of events.** Two random events A and B are said to be *independent* if the conditional probability of A, given the occurrence of B, coincides with the unconditional probability of A,

$$P(A|B) = P(A).$$

In this case, $P(A \cap B) = P(A)P(B)$.

Random events $A_1, \ldots, A_n$ are jointly independent if the relation

$$P\biggl(\bigcap_{k=1}^{m} A_{i_k}\biggr) = \prod_{k=1}^{m} P(A_{i_k})$$

holds whenever $1 \le i_1 < \cdots < i_m \le n$ and $m \le n$.

The pairwise independence of the events A_i and A_j for all $i \ne j$ $(i, j = 1, 2, \ldots, n)$ does not imply that the events $A_1, \ldots, A_n$ are jointly independent.

Example 2. Suppose that the experiment is to draw one of four balls. Let three of them be labeled by the numbers 1, 2, and 3, and let the fourth ball bear all these numbers. By A_i $(i = 1, 2, 3)$ we denote the event that the chosen ball bears the number i. Are the events A_1, A_2, and A_3 dependent?

Since each number is encountered twice, $P(A_1) = P(A_2) = P(A_3) = 1/2$. Since any two distinct numbers are present only on one of the balls, we have $P(A_1A_2) = P(A_2A_3) = P(A_1A_3) = 1/4$, and hence the events A_1, A_2, and A_3 are pairwise independent. All three distinct numbers are present only on one of the balls, and $P(A_1A_2A_3) = 1/4 \ne P(A_1)\,P(A_2)\,P(A_3) = 1/8$.

Thus we see that the events A_1, A_2, and A_3 are jointly dependent, even though they are pairwise independent.

► **Total probability formula. Bayes's formula.** Suppose that a group of pairwise incompatible events $H_1, \ldots, H_n$ is given and their probabilities $P(H_1), \ldots, P(H_n)$ as well as the conditional probabilities $P(A|H_1), \ldots, P(A|H_n)$ of an event A are known. Then the probability of A can be determined by the *total probability formula*

$$P(A) = \sum_{k=1}^{n} P(H_k)\, P(A|H_k). \qquad \text{(M14.1.3.4)}$$

The events H_k are called *hypotheses* with respect to the event A.

Example 3. There are two urns: the first urn contains a white balls and b black ones, and the second urn contains c white balls and d black ones. We take one ball from the first urn and put it into the second urn. After this, we draw one ball from the second urn. Find the probability of the event that this ball is white.

Let A be the event of drawing a white ball. Consider the following group of events:

H_1, a white ball is taken from the first urn and put into the second urn.

H_2, a black ball is taken from the first urn and put into the second urn. Obviously,

$$P(H_1)=\frac{a}{a+b},\quad P(H_2)=\frac{b}{a+b};\quad P(A|H_1)=\frac{c+1}{c+d+1},\quad P(A|H_2)=\frac{c}{c+d+1}.$$

Now by the total probability formula (M14.1.3.4) we obtain

$$P(A)=P(H_1)\,P(A|H_1)+P(H_2)\,P(A|H_2)=\frac{a}{a+b}\,\frac{c+1}{c+d+1}+\frac{b}{a+b}\,\frac{c}{c+d+1}.$$

If it is known that the event A has occurred as a result of one trial but it is unknown which of the events $H_1,\dots,H_n$ has occurred, then the conditional probabilities of the hypotheses H_k (under the condition that the event A has occurred) are calculated using *Bayes's formula*:

$$P(H_k|A)=\frac{P(H_k)\,P(A|H_k)}{P(A)}\qquad(k=1,2,\dots,n).$$

Example 4. A box contains same parts made by two automats, 40% produced by the first automat and the rest by the second. It is known that 3% of the first automat's products are faulty, while the percentage of faulty products made by the second automat is 2%. Find

a) the probability that a randomly chosen part will be faulty and

b) the probability that a randomly chosen part was made by the first automat if found faulty.

Let A denote the event that a randomly chosen part is faulty and let H_1 and H_2 denote the events that a part is made by the first and second automat, respectively. Then

a) the total probability formula gives

$$P(A)=P(H_1)\,P(A|H_1)+P(H_2)\,P(A|H_2)=0.4\cdot 0.03+(1-0.4)\cdot 0.02=0.024;$$

b) Bayes's formula gives

$$P(H_1|A)=\frac{P(H_1)\,P(A|H_1)}{P(A)}=\frac{0.4\cdot 0.03}{0.024}=0.5.$$

M14.1.4. Sequence of Trials

► **Bernoulli process.** In this case, some event A occurs with probability $p=P(A)$ (the probability of "success") and does not occur with probability $q=P(\overline{A})=1-P(A)=1-p$ (the probability of "failure") in each trial. The probability that in n independent trials, the event A ("success") occurs exactly k times is determined by the *Bernoulli formula (binomial distribution)*:

$$P_n(k)=C_n^k p^k(1-p)^{n-k}\qquad(k=0,1,\dots,n).\qquad\text{(M14.1.4.1)}$$

Note that the relation $\sum\limits_{k=0}^{n}P_n(k)=1$ holds.

Example 1. Find the probability that there will be 5 heads in tossing a coin 10 times.

We have $n=10$, $k=5$, and $p=\frac{1}{2}$. Then, by the Bernoulli formula, the desired probability is $P_{10}(5)=C_{10}^5\bigl(\frac{1}{2}\bigr)^5\bigl(\frac{1}{2}\bigr)^{10-5}=\frac{10\cdot9\cdot8\cdot7\cdot6}{5\cdot4\cdot3\cdot2\cdot1}\cdot\frac{1}{2^{10}}=\frac{63}{256}$.

Example 2 (Banach's problem). A smoker mathematician has two matchboxes on him, each of which initially contains exactly n matches. Each time he needs to light a cigarette, he selects a matchbox at random. Find the probability of the event that as the mathematician takes out an empty box for the first time, precisely k matches will be left in the other box ($k \le n$).

The mathematician has taken matches $2n - k$ times, n out of them from the box that is eventually empty. This scheme corresponds to the scheme of $2n - k$ independent Bernoulli trials with n "successes." The probability of a "success" in a single trial is equal to 0.5. The desired probability can be found by the formula

$$P_{2n-k}(n) = C_{2n-k}^{n} p^{n} (1-p)^{n-k} = C_{2n-k}^{n} \left(\tfrac{1}{2}\right)^{2n-k}.$$

The probability that the event occurs at least m times in n independent trials is calculated by the formula

$$P_n(k \ge m) = \sum_{k=m}^{n} P_n(k) = 1 - \sum_{k=0}^{m-1} P_n(k).$$

The probability that the event occurs at least once in n independent trials is calculated by the formula

$$P_n(k \ge 1) = 1 - (1-p)^n.$$

The number n of independent trials necessary for the event to occur at least once with probability at least P is given by the formula

$$n \ge \frac{\ln(1-P)}{\ln(1-p)}.$$

► **Limit formulas for Bernoulli process.** It is very difficult to use Bernoulli's formula (M14.1.4.1) for large n an k. In this case, one has to use approximate formulas for calculating $P_n(k)$ with desired accuracy.

Poisson formula. If the number of independent trials increases unboundedly ($n \to \infty$) and the probability p simultaneously goes to zero ($p \to 0$) so that their product np is a constant ($np = \lambda = \text{const}$), then the probability $P_n(k)$ satisfies the limit relation

$$\lim_{n\to\infty} P_n(k) = \frac{\lambda^k}{k!} e^{-\lambda}. \qquad \text{(M14.1.4.2)}$$

Local de Moivre–Laplace theorem. Suppose that $n \to \infty$, $p = \text{const}$, $0 < p < 1$, and $0 < c_1 \le x_{n,k} = (k - np)[np(1-p)]^{-1/2} \le c_2 < \infty$; then

$$P_n(k) = \frac{1}{\sqrt{2\pi np(1-p)}} \exp\left[-\frac{(k-np)^2}{2np(1-p)}\right] \left[1 + O(1/\sqrt{n}\,)\right] \qquad \text{(M14.1.4.3)}$$

uniformly with respect to $x_{n,k} \in [c_1, c_2]$.

Integral de Moivre–Laplace theorem. Suppose that $n \to \infty$ and $p = \text{const}$, $0 < p < 1$. The probability that the number of successes k in n independent trials is between k_1 and k_2 can be approximately calculated by the formula

$$P_n\{k_1 \le k \le k_2\} \approx \Phi\left(\frac{k_2 - np}{\sqrt{np(1-p)}}\right) - \Phi\left(\frac{k_1 - np}{\sqrt{np(1-p)}}\right). \qquad \text{(M14.1.4.4)}$$

Here

$$\Phi(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{x} \exp\left(-\frac{t^2}{2}\right) dt$$

is the cumulative distribution function of the standard normal distribution (also known as the Laplace function), which is tabulated.

The approximate formula (M14.1.4.2) is normally used for $n \ge 50$ and $np \le 10$. The approximate formulas (M14.1.4.3) and (M14.1.4.4) normally are used for $np(1-p) > 9$.

► **Sequence of n independent trials.** In a series of trials, the trials are said to be *independent* if the occurring events are independent.

Let $p_k = P(A_k)$. Then the probability of the event that n_1 events A_1, n_2 events A_2, …, and n_k events A_k occur in n independent trials is equal to

$$P_n(n_1, \dots, n_k) = \frac{n!}{n_1! \dots n_k!} p_1^{n_1} \dots p_k^{n_k}. \qquad \text{(M14.1.4.5)}$$

Remark. The probability (M14.1.4.5) is the coefficient of $x_1^{n_1} \dots x_k^{n_k}$ in the expansion of the polynomial $(p_1 x_1 + \dots + p_k x_k)^n$ in powers of $x_1, \dots, x_k$.

M14.2. Random Variables and Their Characteristics

M14.2.1. One-Dimensional Random Variables

► **Notion of a random variable. The distribution function of a random variable.** Let $\Omega = \{\omega\}$ be the space of elementary events. A *random variable* X is a real number function $X = X(\omega)$ defined on the set Ω.

Any rule (table, function, graph, or otherwise) that permits one to find the probabilities of events is usually called the distribution law of a random variable. In general, random variables can be *discrete* or *continuous*.

The *cumulative distribution function* of a random variable X is the function $F(x)$ whose value at every point x is equal to the probability of the event $\{X < x\}$:

$$F(x) = P(X < x).$$

Properties of the cumulative distribution function:

1. $0 \le F(x) \le 1$.
2. $\lim\limits_{x\to-\infty} F(x) = F(-\infty) = 0$, $\lim\limits_{x\to+\infty} F(x) = F(+\infty) = 1$.
3. If $x_2 > x_1$, then $F(x_2) \ge F(x_1)$.
4. $P(x_1 \le X < x_2) = F(x_2) - F(x_1)$.
5. $F(x)$ is continuous from the left, i.e., $\lim\limits_{x\to x_0-0} F(x) = F(x_0)$.

► **Discrete random variables.** Let X be a *discrete* random variable assuming the values $x_1, x_2, \dots, x_n, \dots$ with probabilities $p_1, p_2, \dots, p_n, \dots$, so its distribution law can be defined by the table

X	x_1	x_2	…	x_n	…
P	p_1	p_2	…	p_n	…

$$\Bigl(\sum_i p_i = 1\Bigr).$$

(Here and in what follows, it is assumed that the values of a discrete random variable X are arranged in ascending order, so that $x_1 < x_2 < \dots < x_{k-1} < x_k < \cdots$.)

In this case, the cumulative distribution function of a discrete random variable X is the step function defined as the sum

$$F(x) = P\{X < x\} = \sum_{x_n < x} p_n.$$

► **Continuous random variables. The probability density function.** A *continuous random variable* is defined by either a distribution function $F(x)$ or a *probability density function* $p(x)$, which are related by

$$p(x) = F'(x), \quad F(x) = \int_{-\infty}^{x} p(z)\,dz.$$

Sometimes, the distribution function and probability density function of a random variable X are denoted $F_X(x)$ and $p_X(x)$, respectively, rather than $F(x)$ and $p(x)$.

Properties of the probability density function:

1. $p(x) \ge 0$.
2. $p(-\infty) = p(+\infty) = 0$.
3. $\int_{-\infty}^{+\infty} p(x)\,dx = 1$.
4. $P\{a \le X \le b\} = \int_a^b p(x)\,dx$.

The differential $dF(x) = p(x)\,dx \approx P(x \le X \le x + dx)$ is called a *probability element*.

Remark. For continuous random variables, one always has $P(X = x_0) = 0$, but the event $\{X = x_0\}$ is not necessarily impossible.

► **Functions of random variables.** Suppose that a random variable Y is related to a random variable X by a functional dependence $Y = \varphi(X)$. If X is discrete, then, obviously, Y is also discrete. To find the distribution law of the random variable Y, it suffices to calculate the values $\varphi(x_i)$. If there are repeated values among $y_i = \varphi(x_i)$, then these repeated values are taken into account only once, the corresponding probabilities being added.

If X is a continuous random variable with probability density function $p(x)$, then, in general, the random variable Y is also continuous. The cumulative distribution function of Y is given by the formula

$$F_Y(y) = P(Y < y) = P(\varphi(X) < y) = \int_{\varphi(x)<y} p(x)\,dx. \qquad \text{(M14.2.1.1)}$$

If the function $y = \varphi(x)$ is differentiable and monotone on the entire range of the argument x, then the probability density function $p_Y(y)$ of the random variable Y is given by the formula

$$p_Y(y) = p(g(y))\,|g'_y(y)|,$$

where g is the inverse of $\varphi(x)$.

Example 1. Suppose that a random variable X has the probability density

$$p(x) = \frac{1}{\sqrt{2\pi}} e^{-x^2/2}.$$

Find the distribution of the random variable $Y = X^2$.

In this case, $y = \varphi(x) = x^2$. According to (M14.2.1.1), we obtain

$$F_Y(y) = \int_{x^2<y} \frac{1}{\sqrt{2\pi}} e^{-x^2/2}\,dx = \frac{1}{\sqrt{2\pi}} \int_{-\sqrt{y}}^{\sqrt{y}} e^{-x^2/2}\,dx = \frac{2}{\sqrt{2\pi}} \int_0^{\sqrt{y}} e^{-x^2/2}\,dx = \frac{1}{\sqrt{2\pi}} \int_0^y \frac{e^{-t/2}}{\sqrt{t}}\,dt.$$

Example 2. Suppose that a random variable X has the probability density

$$p(x) = \frac{1}{\sqrt{2\pi}\sigma} \exp\Bigl[-\frac{(x-a)^2}{2\sigma^2}\Bigr].$$

Find the probability density of the random variable $Y = e^X$.

For $y > 0$, the cumulative distribution function of the random variable $Y = e^X$ is determined by the relations

$$F_Y(y) = P(Y < y) = P(e^X < y) = P(X < \ln y) = F(\ln y).$$

We differentiate this relation and obtain

$$f_Y(y) = \frac{dF_Y(y)}{dy} = \frac{dF(\ln y)}{dy} = p(\ln y)\frac{1}{y} = \frac{1}{\sqrt{2\pi}\sigma y} \exp\Bigl[-\frac{(\ln y - a)^2}{2\sigma^2}\Bigr] \text{ for } y > 0.$$

The distribution of Y is called the *log-normal distribution*.

Example 3. Suppose that a random variable X has the probability density $p(x)$ for $x \in (-\infty, \infty)$. Then the probability density of the random variable $Y = |X|$ is given by the formula $p_Y(y) = p(x) + p(-x)$ $(y \ge 0)$. In particular, if X is symmetric (i.e., the condition $P(X < -x) = P(X > x)$ holds for all x), then $p_Y(y) = 2p(x)$ $(y \ge 0)$.

M14.2.2. Expectation, Variance and Moments of a Random Variable

► **Expectation.** The *expectation* (*expected value*) $E\{X\}$ *of a discrete or continuous random variable* X is the expression given by the formula

$$E\{X\} = \begin{cases} \displaystyle\sum_i x_i p_i & \text{in the discrete case,} \\ \displaystyle\int_{-\infty}^{+\infty} x p(x)\,dx & \text{in the continuous case.} \end{cases} \qquad \text{(M14.2.2.1)}$$

For the existence of the expectation (M14.2.2.1), it is necessary that the corresponding series or integral converge absolutely.

The expectation is the main characteristic defining the "position" of a random variable, i.e., the number near which its possible values are concentrated.

► **Expectation of function of random variable.** If a random variable Y is related to a random variable X by a functional dependence $Y = \varphi(X)$, then the expectation of the random variable $Y = \varphi(X)$ can be determined by two methods. The first method is to construct the distribution of the random variable Y and then use already known formulas to find $E\{Y\}$. The second method is to use the formulas

$$E\{Y\} = E\{\varphi(X)\} = \begin{cases} \displaystyle\sum_i \varphi(x_i) p_i & \text{in the discrete case,} \\ \displaystyle\int_{-\infty}^{+\infty} \varphi(x) p(x)\,dx & \text{in the continuous case} \end{cases}$$

if these expressions exist in the sense of absolute convergence.

Example. Suppose that a random variable X is uniformly distributed in the interval $(-\pi/2, \pi/2)$, i.e., $p(x) = 1/\pi$ for $x \in (-\pi/2, \pi/2)$ and $p(x) = 0$ for $|x| > \pi/2$. Then the expectation of the random variable $Y = \sin(X)$ is equal to

$$E\{Y\} = \int_{-\infty}^{+\infty} \varphi(x)p(x)\,dx = \int_{-\pi/2}^{\pi/2} \frac{1}{\pi} \sin x\,dx = 0.$$

Properties of the expectation:

1. $E\{a\} = a$ for any real number $a =$ const.
2. $E\{\alpha X + \beta Y\} = \alpha E\{X\} + \beta E\{Y\}$ for any real α and β.
3. $E\{XY\} = E\{X\}E\{Y\}$ for independent random variables X and Y.
4. $|E\{X\}| \le E\{|X|\}$.
5. $E\{X\} \le E\{Y\}$ if $X(\omega) \le Y(\omega)$, $\omega \in \Omega$.
6. $g(E\{X\}) \le E\{g(X)\}$ for convex functions $g(X)$.
7. The *Cauchy–Schwarz inequality* $(E\{|XY|\})^2 \le (E\{X\})^2(E\{Y\})^2$ holds.
8. $E\Big\{\sum\limits_{k=1}^{\infty} X_k\Big\} = \sum\limits_{k=1}^{\infty} E\{X_k\}$ if the series $\sum\limits_{k=1}^{\infty} E\{|X_k|\}$ converges.

► **Moments.** The expectation $E\{(X-a)^k\}$ is called the *kth moment* of the random variable X about the number a. The moments about zero are usually referred to simply as the moments of a random variable. (Sometimes they are called *initial moments*.) The kth moment satisfies the relation

$$\alpha_k = E\{X^k\} = \begin{cases} \displaystyle\sum_i x_i^k p_i & \text{in the discrete case,} \\ \displaystyle\int_{-\infty}^{+\infty} x^k p(x)\,dx & \text{in the continuous case.} \end{cases}$$

If $a = E\{X\}$, then the kth moment of the random variable X about a is called the *kth central moment*. The kth central moment satisfies the relation

$$\mu_k = E\{(X - E\{X\})^k\} = \begin{cases} \displaystyle\sum_i (x_i - E\{X\})^k p_i & \text{in the discrete case,} \\ \displaystyle\int_{-\infty}^{+\infty} (x - E\{X\})^k p(x)\,dx & \text{in the continuous case.} \end{cases}$$

In particular, $\mu_0 = 1$ and $\mu_1 = 0$ for any random variable.

The number $m_k = E\{|X - a|^k\}$ is called the *kth absolute moment* of X about a.

The existence of a kth moment α_k or μ_k implies the existence of the moments α_m and μ_m of all orders $m < k$; if the integral (or series) for α_k or μ_k diverges, then all integrals (series) for α_m and μ_m of orders $m > k$ also diverge.

There is a simple relationship between the central and initial moments:

$$\mu_k = \sum_{m=0}^{k} C_k^m \alpha_m (\alpha_1)^{k-m}, \quad \alpha_0 = 1; \quad \alpha_k = \sum_{m=0}^{k} C_k^m \mu_m (\alpha_1)^{k-m}.$$

The probability distribution is uniquely determined by the moments $\alpha_0, \alpha_1, \ldots$ provided that they all exist and the series $\sum\limits_{m=0}^{\infty} |\alpha_m| t^m / m!$ converges for some $t > 0$.

► **Variance.** The *variance* of a random variable, $\operatorname{Var}\{X\}$, is the measure of the deviation of a random variable X from its expectation $E\{X\}$, determined by the relation

$$\operatorname{Var}\{X\} = E\{(X - E\{X\})^2\}.$$

The variance $\operatorname{Var}\{X\}$ is the second central moment of the random variable X. The variance can be determined by the formulas

$$\operatorname{Var}\{X\} = \begin{cases} \displaystyle\sum_i (x_i - E\{X\})^2 p_i & \text{in the discrete case,} \\ \displaystyle\int_{-\infty}^{+\infty} (x - E\{X\})^2 p(x)\,dx & \text{in the continuous case.} \end{cases}$$

The variance characterizes the spread in values of the random variable X about its expectation.

Properties of the variance:

1. $\operatorname{Var}\{a\} = 0$ for any real number $a = \text{const}$.
2. The variance is nonnegative: $\operatorname{Var}\{X\} \geq 0$.
3. $\operatorname{Var}\{X\} = E\{X^2\} - (E\{X\})^2$.
4. $\operatorname{Var}\{\alpha X + \beta\} = \alpha^2 \operatorname{Var}\{X\}$ for any real numbers α and β.
5. $\operatorname{Var}\{X \pm Y\} = \operatorname{Var}\{X\} + \operatorname{Var}\{Y\}$ for independent random variables X and Y.
6. If X and Y are independent random variables, then

$$\operatorname{Var}\{XY\} = \operatorname{Var}\{X\}\operatorname{Var}\{Y\} + \operatorname{Var}\{X\}(E\{Y\})^2 + \operatorname{Var}\{Y\}(E\{X\})^2.$$

7. $\min\limits_m E\{(X - m)^2\} = \operatorname{Var}\{X\}$ and is attained for $m = E\{X\}$.

► **Other numerical characteristics of random variables.** The *standard deviation (root mean square deviation)* of a random variable X is the square root of its variance,

$$\sigma = \sqrt{\mathrm{Var}\{X\}}.$$

The standard deviation has the same dimension as the random variable itself.

The *coefficient of variation* is the ratio of the standard deviation to the expected value,

$$v = \frac{\sigma}{E\{X\}}.$$

The *asymmetry coefficient*, or *skewness*, is defined by the formula

$$\gamma_1 = \frac{\mu_3}{(\mu_2)^{3/2}}.$$

If $\gamma_1 > 0$, then the distribution curve is more flattened to the right of the mode $\mathrm{Mode}\{X\}$; if $\gamma_1 < 0$, then the distribution curve is more flattened to the left of the mode $\mathrm{Mode}\{X\}$ (see Fig. M14.1).

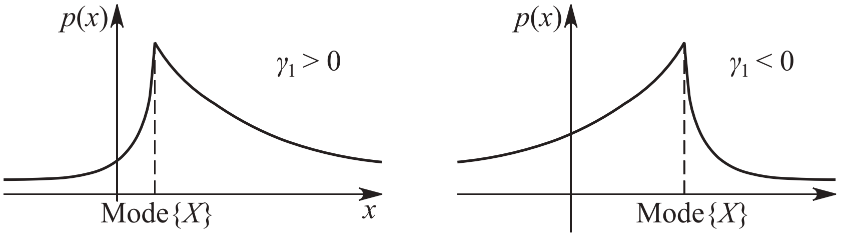

Figure M14.1. Relationship between the distribution curve and the asymmetry coefficient.

The *excess coefficient*, or *excess*, or *kurtosis*, is defined by the formula

$$\gamma_2 = \frac{\mu_4}{\mu_2^2} - 3.$$

One says that for $\gamma_2 = 0$ the distribution has a normal excess, for $\gamma_2 > 0$ the distribution has a positive excess, and for $\gamma_2 < 0$ the distribution has a negative excess.

Remark. The coefficients γ_1^2 and $\gamma_2 + 3$ or $(\gamma_2 + 3)/2$ are often used instead of γ_1 and γ_2.

A *mode* $\mathrm{Mode}\{X\}$ *of a continuous probability distribution* is a point of local maximum of the probability density function $p(x)$. A *mode of a discrete probability distribution* is a value preceded and followed by values having probabilities smaller than $p(\mathrm{Mode}\{X\})$.

Distributions with one, two, or more modes are said to be *unimodal*, *bimodal*, or *multimodal*, respectively.

M14.2.3. Main Discrete Distributions and Their Numerical Characteristics

► **Binomial distribution.** A random variable X has a *binomial distribution* with parameters n and p if

$$P_n(k) = P(X = k) = C_n^k p^k (1-p)^{n-k}, \quad k = 0, 1, \dots, n,$$

where $0 < p < 1$ and $n \ge 1$.

The cumulative distribution function has the form

$$F(x) = \begin{cases} 1 & \text{for } x > n, \\ \sum\limits_{k=1}^{m} C_n^k p^k (1-p)^{n-k} & \text{for } m \le x < m+1 \ \ (m = 1, 2, \ldots, n-1), \\ 0 & \text{for } x < 0, \end{cases}$$

and the numerical characteristics are given by the formulas

$$E\{X\} = np, \quad \operatorname{Var}\{X\} = np(1-p), \quad \gamma_1 = \frac{1-2p}{\sqrt{np(1-p)}}, \quad \gamma_2 = \frac{1-6p(1-p)}{np(1-p)}.$$

The binomial distribution is a model of random experiments consisting of n independent identical Bernoulli trials. If $X_1, \ldots, X_n$ are independent random variables, each of which can take only two values 1 or 0 with probabilities p and $q = 1 - p$, respectively, then the random variable $X = \sum\limits_{k=1}^{n} X_k$ has the binomial distribution with parameters (n, p).

See also the limit formulas (M14.1.4.2)–(M14.1.4.4) for the Bernoulli process.

► **Geometric distribution.** A random variable X has a *geometric distribution* with parameter p $(0 < p < 1)$ if

$$P(X = k) = p(1-p)^k, \quad k = 0, 1, 2, \ldots$$

Numerical characteristics for the geometric distribution can be calculated by the formulas

$$E\{X\} = \frac{1-p}{p}, \quad \operatorname{Var}\{X\} = \frac{1-p}{p^2}, \quad \alpha_2 = \frac{(1-p)(2-p)}{p^2}, \quad \gamma_1 = \frac{2-p}{\sqrt{1-p}}, \quad \gamma_2 = 6 + \frac{p^2}{1-p}.$$

The geometric distribution has a maximum at $k = 0$ and decreases monotonically with increasing k.

The geometric distribution describes a random variable X equal to the number of failures before the first success in a sequence of Bernoulli trials with probability p of success in each trial.

The geometric distribution is the only discrete distribution that is *memoryless*, i.e., satisfies the relation

$$P(X > t + s \mid X > t) = P(X > s)$$

for any $s > 0$ and $t > 0$. This property permits one to view the geometric distribution as the discrete analogue of the exponential distribution (see Subsection M14.2.4).

► **Hypergeometric distribution.** A random variable X has a *hypergeometric distribution* with parameters N, p, and n if

$$P(X = k) = \frac{C_{Np}^{k} C_{N(1-p)}^{n-k}}{C_N^n}, \quad k = 0, 1, \ldots, n,$$

where $0 < p < 1$, $0 \le n \le N$, and $N > 0$.

The numerical characteristics are given by the formulas

$$E\{X\} = np, \quad \operatorname{Var}\{X\} = \frac{N-n}{N-1} np(1-p).$$

A typical scheme in which the hypergeometric distribution arises is as follows: n elements are randomly drawn without replacement from a population of N elements containing exactly Np elements of type I and $N(1-p)$ elements of type II. The number of elements of type I in the sample is described by the hypergeometric distribution.

If $n \ll N$ (in practice, $n < 0.1N$), then

$$\frac{C_{Np}^{k} C_{N(1-p)}^{n-k}}{C_{N}^{n}} \approx C_{n}^{k} p^{k} (1-p)^{n-k};$$

i.e., the hypergeometric distribution tends to the binomial distribution.

► **Poisson distribution.** A random variable X has a *Poisson distribution* with parameter λ ($\lambda > 0$) if

$$P(X = k) = \frac{\lambda^k}{k!} e^{-\lambda}, \quad k = 0, 1, 2, \dots$$

The cumulative distribution function of the Poisson distribution at the points $k = 0, 1, 2, \dots$ is given by the formula

$$F(k) = \frac{1}{k!} \int_{\lambda}^{\infty} x^k e^{-x}\, dx,$$

and the numerical characteristics are given by

$$\begin{gathered} E\{X\} = \lambda, \quad \operatorname{Var}\{X\} = \lambda, \quad \alpha_2 = \lambda^2 + \lambda, \quad \alpha_3 = \lambda(\lambda^2 + 3\lambda + 1), \\ \alpha_4 = \lambda(\lambda^3 + 6\lambda^2 + 7\lambda + 1), \quad \mu_3 = \lambda, \quad \mu_4 = 3\lambda^2 + \lambda, \quad \gamma_1 = \lambda^{-1/2}, \quad \gamma_2 = \lambda^{-1}. \end{gathered}$$

The sum of independent random variables $X_1, \dots, X_n$ obeying the Poisson distributions with parameters $\lambda_1, \dots, \lambda_n$, respectively, has the Poisson distribution with parameter $\lambda_1 + \dots + \lambda_n$.

The Poisson distribution is the limit distribution for many discrete distributions such as the hypergeometric distribution, the binomial distribution, the negative binomial distribution, distributions arising in problems of arrangement of particles in cells, etc. The Poisson distribution is an acceptable model for describing the random number of occurrences of certain events on a given time interval in a given domain in space.

► **Negative binomial distribution.** A random variable X has a *negative binomial distribution* with parameters r and p if

$$P(X = k) = C_{r+k-1}^{r-1} p^r (1-p)^k, \quad k = 0, 1, \dots, r,$$

where $0 < p < 1$ and $r > 0$.

The numerical characteristics can be calculated by the formulas

$$E\{X\} = \frac{r(1-p)}{p}, \quad \operatorname{Var}\{X\} = \frac{r(1-p)}{p^2}, \quad \gamma_1 = \frac{2-p}{\sqrt{r(1-p)}}, \quad \gamma_2 = \frac{6}{r} + \frac{p^2}{r(1-p)}.$$

The negative binomial distribution describes the number X of failures before the rth success in a Bernoulli process with probability p of success on each trial. For $r = 1$, the negative binomial distribution coincides with the geometric distribution.

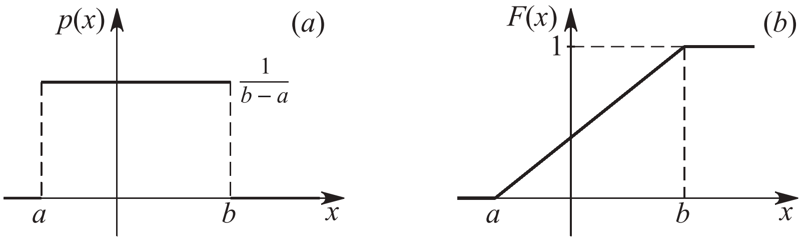

Figure M14.2. Probability density function (*a*) and cumulative distribution function (*b*) of a uniform distribution.

M14.2.4. Main Continuous Distributions and Their Numerical Characteristics

► **Uniform distribution.** A random variable X is *uniformly* distributed on an interval $[a, b]$ (Fig. M14.2 *a*) if

$$p(x) = \begin{cases} \dfrac{1}{b-a} & \text{for } x \in [a, b], \\ 0 & \text{for } x \notin [a, b]. \end{cases}$$

The cumulative distribution function (see Fig. M14.2 *b*) has the form

$$F(x) = \begin{cases} 0 & \text{for } x \le a, \\ \dfrac{x-a}{b-a} & \text{for } a < x \le b, \\ 1 & \text{for } x > b, \end{cases}$$

and the numerical characteristics are given by the expressions

$$E\{X\} = \frac{a+b}{2}, \quad \operatorname{Var}\{X\} = \frac{(b-a)^2}{12}, \quad \gamma_1 = 0, \quad \gamma_2 = -1.2.$$

The uniform distribution does not have a mode.

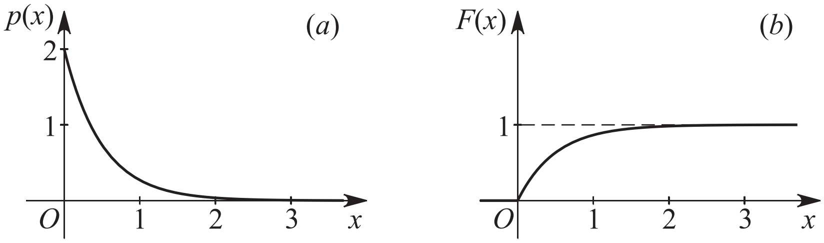

Figure M14.3. Probability density function (*a*) and cumulative distribution function (*b*) of an exponential distribution for $\lambda = 2$.

► **Exponential distribution.** A random variable X has the *exponential distribution* with parameter $\lambda > 0$ (Fig. M14.3 *a*) if

$$p(x) = \begin{cases} \lambda e^{-\lambda x} & \text{for } x > 0, \\ 0 & \text{for } x \le 0. \end{cases}$$

The cumulative distribution function (see Fig. M14.3 *b*) has the form

$$F(x) = \begin{cases} 1 - e^{-\lambda x} & \text{for } x > 0, \\ 0 & \text{for } x \le 0, \end{cases}$$

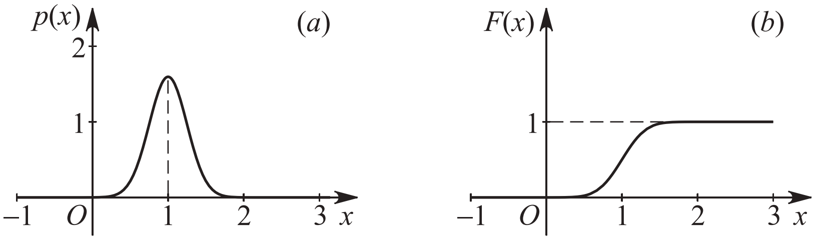

Figure M14.4. Probability density function (*a*) and cumulative distribution function (*b*) of a normal distribution for $a = 1$ and $\sigma = 1/4$.

and the numerical characteristics are given by the formulas

$$E\{X\} = \frac{1}{\lambda}, \quad \operatorname{Var}\{X\} = \frac{1}{\lambda^2}, \quad \alpha_2 = \frac{2}{\lambda^2}, \quad \gamma_1 = 2, \quad \gamma_2 = 6.$$

The exponential distribution is the continuous analogue of the geometric distribution and is memoryless: $P(X > t + s \mid X > t) = P(X > s)$.

► **Normal distribution.** A random variable X has a *normal distribution* with parameters a and σ^2 (see Fig. M14.4 *a*) if its probability density function has the form

$$p(x) = \frac{1}{\sqrt{2\pi}\sigma} \exp\left[-\frac{(x-a)^2}{2\sigma^2}\right], \quad x \in (-\infty, \infty).$$

The cumulative distribution function (see Fig. M14.4 *b*) has the form

$$F(x) = \frac{1}{\sqrt{2\pi}\,\sigma} \int_{-\infty}^{x} \exp\left[-\frac{(t-a)^2}{2\sigma^2}\right] dt \equiv \frac{1}{2}\left[1 + \operatorname{erf}\left(\frac{x-a}{\sqrt{2}\,\sigma}\right)\right],$$

where erf z is the error function (see Section M13.2).

The numerical characteristics are given by the formulas

$$E\{X\} = a, \quad \operatorname{Var}\{X\} = \sigma^2, \quad \operatorname{Mode}\{X\} = a, \quad \gamma_1 = 0, \quad \gamma_2 = 0,$$
$$\mu_k = \begin{cases} 0, & k = 2l-1, \ l = 1, 2, \ldots \\ (2k-1)!!\,\sigma^{2k}, & k = 2l, \ l = 1, 2, \ldots \end{cases}$$

The linear transformation $Y = \frac{X-a}{\sigma}$ reduces the normal distribution with parameters (a, σ^2) and cumulative distribution function $F(x)$ to the standard normal distribution with parameters $(0, 1)$ and cumulative distribution function

$$\Phi(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{x} e^{-t^2/2}\, dt. \qquad \text{(M14.2.4.1)}$$

The probability that a random variable X normally distributed with parameters (m, σ^2) lies in the interval (a, b) is given by the formula

$$P(a < x < b) = \Phi\left(\frac{b-m}{\sigma}\right) - \Phi\left(\frac{a-m}{\sigma}\right).$$

A normally distributed random variable takes values close to its expectation with large probability; this is expressed by the *sigma rule*

$$P(|X-m|\ge k\sigma)=2[1-\Phi(k)]=\begin{cases}0.3173 & \text{for } k=1,\\ 0.0456 & \text{for } k=2,\\ 0.0027 & \text{for } k=3.\end{cases}$$

The three-sigma rule is most frequently used.

The fundamental role of the normal distribution is due to the fact that, under mild assumptions, the distribution of a sum of random variables is asymptotically normal as the number of terms increases. The corresponding conditions are specified in the central limit theorem.

► **Chi-square distribution.** A random variable $X=\chi^2(n)$ has a *chi-square distribution* with n degrees of freedom if its probability density function has the form

$$p(x)=\begin{cases}\dfrac{1}{2^{n/2}\,\Gamma(n/2)}x^{-1+n/2}e^{-x/2} & \text{for } x>0,\\ 0 & \text{for } x\le 0,\end{cases}\qquad\text{(M14.2.4.2)}$$

where $\Gamma(z)$ is the Gamma function (see Subsection M13.4.1).

The cumulative distribution function can be written as

$$F(x)=\frac{1}{2^{n/2}\Gamma(n/2)}\int_0^x \xi^{-1+n/2}e^{-\xi/2}\,d\xi$$

and the numerical characteristics are given by the formulas

$$E\{\chi^2(n)\}=n,\quad \operatorname{Var}\{\chi^2(n)\}=2n,\quad \alpha_k=n(n+2)\cdot\ldots\cdot[n+2(k-1)],$$
$$\gamma_1=2\sqrt{\frac{2}{n}},\quad \gamma_2=\frac{12}{n},\quad \operatorname{Mode}\{\chi^2(n)\}=n-2\quad (n\ge 2).$$

Main property of the chi-square distribution. For an arbitrary n, the sum

$$X=\sum_{k=1}^{n}X_k^2,$$

of squares of independent random variables obeying the standard normal distribution has the chi-square distribution with n degrees of freedom.

Relationship with other distributions:

1. For $n=1$, formula (M14.2.4.2) gives the probability density function of the square X^2 of a random variable with the standard normal distribution.
2. For $n=2$, formula (M14.2.4.2) gives the exponential distribution with parameter $\lambda=\frac{1}{2}$.
3. As $n\to\infty$, the random variable $X=\chi^2(n)$ has an asymptotically normal distribution with parameters $(n,2n)$.
4. As $n\to\infty$, the random variable $\sqrt{2\chi^2(n)}$ has an asymptotically normal distribution with parameters $(\sqrt{2n-1},1)$.

M14.2.5. Two-dimensional and Multivariate Random Variables

► **Distribution of bivariate random variable.** Suppose that random variables X_1 and X_2 are defined in a probability space Ω_2; then one says that a *two-dimensional random vector* $\mathbf{X} = (X_1, X_2)$ or a *system of two random variables* is given.

The *distribution function* $F(x_1, x_2)$ (also denoted $F_{X_1,X_2}(x_1, x_2)$) *of a two-dimensional random vector* (X_1, X_2), or the *joint distribution function of the random variables* X_1 and X_2, is defined as the probability of the simultaneous occurrence (intersection) of the events $(X_1 < x_1)$ and $(X_2 < x_2)$; i.e.,

$$F(x_1, x_2) = P(X_1 < x_1, X_2 < x_2).$$

Properties of the joint distribution function of random variables X_1 and X_2:

1. The function $F(x_1, x_2)$ is a nondecreasing function of each of the arguments.
2. $F(x_1, -\infty) = F(-\infty, x_2) = F(-\infty, -\infty) = 0$.
3. $F(+\infty, +\infty) = 1$.
4. The probability that the random vector lies in a rectangle with sides parallel to the coordinate axes is

$$P(a_1 \le X_1 < b_1, a_2 \le X_2 < b_2) = F(b_1, b_2) - F(b_1, a_2) - F(a_1, b_2) + F(a_1, a_2).$$

5. The function $F(x_1, x_2)$ is left-continuous in either argument.

► **Discrete bivariate random variables.** A bivariate random variable (X_1, X_2) is said to be *discrete* if each of the random variables X_1 and X_2 is discrete.

If the random variable X_1 takes the values $x_{11}, \ldots, x_{1m}$ and the random variable X_2 takes the values $x_{21}, \ldots, x_{2n}$, then the random vector (X_1, X_2) can take only the pairs of values (x_{1i}, x_{2j}) $(i = 1, \ldots, m,\ j = 1, \ldots, n)$. The entries $p_{ij} = P(X_1 = x_{1i}, X_2 = x_{2j})$ are the probabilities of the simultaneous occurrence of the events $(X_1 = x_{1i})$ and $(X_2 = x_{2j})$; $P_{X_1,i} = p_{i1} + \cdots + p_{in}$ is the probability that the random variable X_1 takes the value x_{1i}; $P_{X_2,j} = p_{1j} + \cdots + p_{mj}$ is the probability that the random variable X_2 takes the value x_{2j}.

The distribution function of a discrete bivariate random variable can be determined by the formula

$$F(x_1, x_2) = \sum_{\substack{x_{1i} < x_1 \\ x_{2j} < x_2}} p_{ij}.$$

► **Continuous bivariate random variables.** A bivariate random variable (X_1, X_2) is said to be *continuous* if its joint distribution function $F(x_1, x_2)$ can be represented as

$$F(x_1, x_2) = \int_{-\infty}^{x_2} \int_{-\infty}^{x_1} p(y_1, y_2)\, dy_1\, dy_2, \qquad \text{(M14.2.5.1)}$$

where the *joint probability density function* $p(x_1, x_2)$ is piecewise continuous.

The joint probability density function can be expressed in terms of the joint distribution function as follows:

$$p(x_1, x_2) = \frac{\partial^2}{\partial x_1 \partial x_2} F(x_1, x_2). \qquad \text{(M14.2.5.2)}$$

Formulas (M14.2.5.1) and (M14.2.5.2) establish a one-to-one correspondence (up to sets of probability zero) between the joint probability density functions and the joint distribution functions of continuous bivariate random variables. The differential $p(x_1, x_2)\, dx_1\, dx_2$ is called a *probability element*. Up to higher-order infinitesimals, the probability element is equal to the probability for the random variable (X_1, X_2) to lie in the infinitesimal rectangle $(x_1, x_1 + \Delta x_1) \times (x_2, x_2 + \Delta x_2)$.

Properties of the joint probability density function of random variables X_1 and X_2:

1. The function $p(x_1, x_2)$ is nonnegative; i.e., $p(x_1, x_2) \ge 0$.
2. $\displaystyle\int_{-\infty}^{+\infty}\int_{-\infty}^{+\infty} p(x_1, x_2)\,dx_1\,dx_2 = 1$.
3. $\displaystyle P(a_1 < X_1 < b_1, a_2 < X_2 < b_2) = \int_{a_1}^{b_1} dx_1 \int_{a_2}^{b_2} p(x_1, x_2)\,dx_2 = \int_{a_2}^{b_2} dx_2 \int_{a_1}^{b_1} p(x_1, x_2)\,dx_1$.
4. The probability for a two-dimensional random variable (X_1, X_2) to lie in a domain $D \subset \mathbb{R}^2$ is numerically equal to the volume of the curvilinear cylinder with base D bounded above by the surface of the joint probability density function:

$$P[(X_1, X_2) \in D] = \iint_{(x_1,x_2)\in D} p_{X_1,X_2}(x_1, x_2)\,dx_1\,dx_2.$$

Random variables X_1 and X_2 are said to be *independent* if the relation

$$P(X_1 \in S_1, X_2 \in S_2) = P(X_1 \in S_1)\,P(X_2 \in S_2)$$

holds for any measurable sets S_1 and S_2.

THEOREM. *Random variables X_1 and X_2 are independent if and only if*

$$F(x_1, x_2) = F_1(x_1)\,F_2(x_2),$$

where F_1 and F_2 are the cumulative distribution functions of X_1 and X_2, respectively.

► **Numerical characteristics of bivariate random variables.** The *expectation* of a function $\varphi(X_1, X_2)$ of a bivariate random variable (X_1, X_2) is defined as the expression computed by the formula

$$E\{\varphi(X_1, X_2)\} = \begin{cases} \displaystyle\sum_i \sum_j \varphi(x_{1i}, x_{2j}) p_{ij} & \text{in the discrete case,} \\ \displaystyle\int_{-\infty}^{+\infty}\int_{-\infty}^{+\infty} \varphi(x_1, x_2) p(x_1, x_2)\,dx_1\,dx_2 & \text{in the continuous case,} \end{cases}$$

if these expressions exist in the sense of absolute convergence; otherwise, one says that $E\{\varphi(X_1, X_2)\}$ does not exist.

The *moment of order* $r_1 + r_2$ of a two-dimensional random variable (X_1, X_2) about a point (a_1, a_2) is defined as the expectation $E\{(X_1 - a_1)^{r_1}(X_2 - a_2)^{r_2}\}$.

If $a_1 = a_2 = 0$, then the moment of order $r_1 + r_2$ of a two-dimensional random variable (X_1, X_2) is called simply the moment, or the *initial moment*. The initial moment of order $r_1 + r_2$ is usually denoted by α_{r_1,r_2}; i.e., $\alpha_{r_1,r_2} = E\{X_1^{r_1} X_2^{r_2}\}$.

The first initial moments are the expectations of the random variables X_1 and X_2; i.e., $\alpha_{1,0} = E\{X_1^1 X_2^0\} = E\{X_1\}$ and $\alpha_{0,1} = E\{X_1^0 X_2^1\} = E\{X_2\}$. The point $(E\{X_1\}, E\{X_2\})$ on the OXY-plane characterizes the position of the random point (X_1, X_2); this position spreads about the point $(E\{X_1\}, E\{X_2\})$.

If $a_1 = E\{X_1\}$ and $a_2 = E\{X_2\}$, then the moment of order $r_1 + r_2$ of the bivariate random variable (X_1, X_2) is called the *central moment*. The central moment of order $r_1 + r_2$

is usually denoted by μ_{r_1,r_2}; i.e., $\mu_{r_1,r_2} = E\{(X_1 - E\{X_1\})^{r_1}(X_2 - E\{X_2\})^{r_2}\}$. Obviously, the first central moments are zero.

The second central moments are of special interest and have special names and notation:

$$\lambda_{11} = \mu_{2,0} = \operatorname{Var}\{X_1\}, \quad \lambda_{22} = \mu_{0,2} = \operatorname{Var}\{X_2\},$$

$$\lambda_{12} = \lambda_{21} = \mu_{1,1} = E\{(X_1 - E\{X_1\})(X_2 - E\{X_2\})\}.$$

The first two of these moments are the variances of the respective random variables, and the third one is called the *covariance* and will be considered below.

► **Covariance and correlation of two random variables.** The *covariance* (correlation moment, or mixed second moment) $\operatorname{Cov}(X_1, X_2)$ of random variables X_1 and X_2 is defined as the central moment of order (1 + 1):

$$\operatorname{Cov}(X_1, X_2) = \alpha_{1,1} = E\{(X_1 - E\{X_1\})(X_2 - E\{X_2\})\}.$$

Properties of the covariance:

1. $\operatorname{Cov}(X_1, X_2) = \operatorname{Cov}(X_2, X_1)$.
2. $\operatorname{Cov}(X, X) = \operatorname{Var}\{X\}$.
3. If the random variables X_1 and X_2 are independent, then $\operatorname{Cov}(X_1, X_2) = 0$ and if $\operatorname{Cov}(X_1, X_2) \neq 0$, then the random variables X_1 and X_2 are dependent.
4. If $Y_1 = a_1X_1 + b_1$ and $Y_2 = a_2X_2 + b_2$, then $\operatorname{Cov}(Y_1, Y_2) = a_1a_2\operatorname{Cov}(X_1, X_2)$.
5. $\operatorname{Cov}(X_1, X_2) = E\{X_1X_2\} - E\{X_1\}E\{X_2\}$.
6. $|\operatorname{Cov}(X_1, X_2)| \le \sqrt{\operatorname{Var}\{X_1\}\operatorname{Var}\{X_2\}}$. Moreover, $\operatorname{Cov}(X_1, X_2) = \pm\sqrt{\operatorname{Var}\{X_1\}\operatorname{Var}\{X_2\}}$ if and only if the random variables X_1 and X_2 are linearly dependent.
7. $\operatorname{Var}\{X_1 + X_2\} = \operatorname{Var}\{X_1\} + \operatorname{Var}\{X_2\} + 2\operatorname{Cov}(X_1, X_2)$.

If $\operatorname{Cov}(X_1, X_2) = 0$, then the random variables X_1 and X_2 are said to be *uncorrelated*; if $\operatorname{Cov}(X_1, X_2) \neq 0$, then they are *correlated*. Independent random variables are always uncorrelated, but uncorrelated random variables are not necessarily independent in general.

Example. Suppose that we roll two dice. Let X_1 be the number on the first die and let X_2 be the number on the second die. We consider the random variables $Y_1 = X_1 + X_2$ and $Y_2 = X_1 - X_2$ (the sum and difference of the points obtained). Then

$$\begin{aligned}\operatorname{Cov}(Y_1, Y_2) &= E\{(X_1 + X_2 - E\{X_1 + X_2\})(X_1 - X_2 - E\{X_1 - X_2\})\}\\ &= E\{(X_1 - E\{X_1\})^2 - (X_2 - E\{X_2\})^2\}\\ &= \operatorname{Var}\{X_1\} - \operatorname{Var}\{X_2\} = 0,\end{aligned}$$

since X_1 and X_2 are identically distributed and hence $\operatorname{Var}\{X_1\} = \operatorname{Var}\{X_2\}$. But Y_1 and Y_2 are obviously dependent; for example, if $Y_1 = 2$ then one necessarily has $Y_2 = 0$.

The covariance of random variables X_1 and X_2 characterizes both their dependence on each other and their spread around the point $(E\{X_1\}, E\{X_2\})$. The covariance of X_1 and X_2 has the dimension equal to the product of dimensions of X_1 and X_2. Along with the covariance of X_1 and X_2, one often uses the coefficient of correlation $\rho(X_1, X_2)$, which is a dimensionless normalized quantity. The *correlation coefficient* of random variables X_1 and X_2 is the ratio of the covariance of X_1 and X_2 to the product of their standard deviations,

$$\rho(X_1, X_2) = \frac{\operatorname{Cov}(X_1, X_2)}{\sigma_1\sigma_2}.$$

The correlation coefficient of random variables X_1 and X_2 indicates the degree of linear dependence between the variables. If $\rho(X_1, X_2) = 0$, then there is no linear relation between the random variables, but there may well be some other relation between them.

Properties of the correlation coefficient:

1. $\rho(X_1, X_2) = \rho(X_2, X_1)$.
2. $\rho(X, X) = 1$.
3. If random variables X_1 and X_2 are independent, then $\rho(X_1, X_2) = 0$. If $\rho(X_1, X_2) \neq 0$, then the random variables X_1 and X_2 are dependent.
4. If $Y_1 = a_1 X_1 + b_1$ and $Y_2 = a_2 X_2 + b_2$, then $\rho(Y_1, Y_2) = \pm\rho(X_1, X_2)$.
5. $|\rho(X_1, X_2)| \le 1$. Moreover, $\rho(X_1, X_2) = \pm 1$ if and only if the random variables X_1 and X_2 are linearly dependent.

The theory of distribution functions of multivariate random variables (random vectors) can be developed in a similar way.

M14.3. Limit Theorems

M14.3.1. Convergence of Random Variables

► **Convergence in probability.** A sequence of random variables X_1, X_2, … is said to *converge in probability* to a random variable $X (X_n \xrightarrow{P} X)$ if

$$\lim_{n\to\infty} P(|X_n - X| \ge \varepsilon) = 0$$

for any $\varepsilon > 0$, i.e., if for any $\varepsilon > 0$ and $\delta > 0$ there exists a number N, depending on ε and δ, such that the inequality

$$P(|X_n - X| \ge \varepsilon) < \delta$$

holds for $n > N$. A sequence of k-dimensional random variables $\mathbf{X}_n$ is said to converge in probability to a random variable $\mathbf{X}$ if each coordinate of the random variable $\mathbf{X}_n$ converges in probability to the respective coordinate of the random variable $\mathbf{X}$.

► **Convergence in the mean.** A sequence of random variables X_1, X_2, … with finite qth initial moments ($E\{X^q\} < \infty$, $q = 1, 2, \ldots$) is said to *converge in the qth mean* to a random variable X if

$$\lim_{n\to\infty} E\{|X_n - X|^q\} = 0.$$

Convergence in the qth mean for $q = 2$ is called *convergence in mean square*. If $X_n \to X$ in the qth mean then $X_n \to X$ in the q_1th mean for all $q_1 \le q$.

Convergence in the qth mean implies convergence in probability. The converse statement is generally not true.

► **Convergence in distribution.** Suppose that a sequence $F_1(x)$, $F_2(x)$, … of cumulative distribution functions converges to a distribution function $F(x)$,

$$\lim_{n\to\infty} F_n(x) = F(x),$$

for every point x. In this case, we say that the sequence X_1, X_2, … of the corresponding random variables converges to the random variable X *in distribution*. The random variables X_1, X_2, … can be defined on different probability spaces.

A sequence $F_1(x)$, $F_2(x)$, … of distribution functions *weakly converges* to a distribution function $F(x)$ ($F_n \to F$) if

$$\lim_{n\to\infty} E\{h(X_n)\} = E\{h(X)\}$$

for any bounded continuous function h.

Convergence in distribution and weak convergence of distribution functions are equivalent.

The weak convergence $F_{X_n} \to F$ for random variables having a probability density function means the convergence

$$\int_{-\infty}^{+\infty} g(x)p_{X_n}(x)\,dx \to \int_{-\infty}^{+\infty} g(x)p(x)\,dx$$

for any bounded continuous function $g(x)$, where $p(x) = \lim\limits_{n\to\infty} p_{X_n}(x)$.

M14.3.2. Limit Theorems

► **Law of large numbers.** The law of large numbers consists of several theorems establishing the stability of average results and revealing conditions for this stability to occur.

The notion of convergence in probability is most often used for the case in which the limit random variable X has the degenerate distribution concentrated at a point a ($P(X = a) = 1$) and

$$X_n = \frac{1}{n}\sum_{k=1}^{n} Y_k,$$

where $Y_1, Y_2, \dots$ are arbitrary random variables.

A sequence $Y_1, Y_2, \dots$ satisfies the *weak law of large numbers* if the limit relation

$$\lim_{n\to\infty} P\Bigl(\Bigl|\frac{1}{n}\sum_{k=1}^{n} Y_k - a\Bigr| \ge \varepsilon\Bigr) \equiv \lim_{n\to\infty} P(|X_n - a| \ge \varepsilon) = 0 \qquad \text{(M14.3.2.1)}$$

holds for any $\varepsilon > 0$.

If the relation

$$P\Bigl(\omega \in \Omega : \lim_{n\to\infty} \frac{1}{n}\sum_{k=1}^{n} Y_k = a\Bigr) \equiv P\bigl(\omega \in \Omega : \lim_{n\to\infty} X_n = a\bigr) = 1$$

is satisfied instead of (M14.3.2.1), i.e., the sequence X_n converges to the number a with probability 1, then the sequence $Y_1, Y_2, \dots$ satisfies the *strong law of large numbers*.

Markov's inequality. For any nonnegative random variable X that has an expectation $E\{X\}$, the inequality

$$P(X \ge \varepsilon) \le \frac{E\{X\}}{\varepsilon} \qquad \text{(M14.3.2.2)}$$

holds for any $\varepsilon > 0$. It follows from inequality (M14.3.2.2) that

$$P(X < \varepsilon) \ge 1 - \frac{E\{X\}}{\varepsilon}.$$

Chebyshev's inequality. For any random variable X with finite variance, the inequality

$$P(|X - E\{X\}| \ge \varepsilon) \le \frac{\operatorname{Var}\{X\}}{\varepsilon^2} \qquad \text{(M14.3.2.3)}$$

holds for any $\varepsilon > 0$. It follows from inequality (M14.3.2.3) that

$$P(|X - E\{X\}| < \varepsilon) \ge 1 - \frac{\operatorname{Var}\{X\}}{\varepsilon^2}$$

CHEBYSHEV'S THEOREM. *If* $X_1, X_2, \dots$ *is a sequence of pairwise independent random variables with uniformly bounded finite variances,* $\operatorname{Var}\{X_1\} \le C$, $\operatorname{Var}\{X_2\} \le C$, $\dots$, *then the limit relation*

$$\lim_{n\to\infty} P\biggl(\biggl|\frac{1}{n}\sum_{k=1}^{n} X_k - \frac{1}{n}\sum_{k=1}^{n} E\{X_k\}\biggr| < \varepsilon\biggr) = 1$$

holds for any $\varepsilon > 0$.

BERNOULLI'S THEOREM. *Let* μ_n *be the number of occurrences of an event* A *(the number of successes) in* n *independent trials, and let* $p = P(A)$ *be the probability of the occurrence of the event* A *(the probability of success) in each of the trials. Then the sequence of relative frequencies* μ_n/n *of the occurrence of the event* A *in* n *independent trials converges in probability to* $p = P(A)$ *as* $n \to \infty$*; i.e., the limit relation*

$$\lim_{n\to\infty} P\biggl(\biggl|\frac{\mu_n}{n} - p\biggr| < \varepsilon\biggr) = 1$$

holds for any $\varepsilon > 0$.

POISSON'S THEOREM. *If in a sequence of independent trials the probability that an event* A *occurs in the* k*th trial is equal to* p_k*, then*

$$\lim_{n\to\infty} P\biggl(\biggl|\frac{\mu_n}{n} - \frac{p_1 + \cdots + p_n}{n}\biggr| < \varepsilon\biggr) = 1.$$

KOLMOGOROV'S THEOREM. *If a sequence of independent random variables* $X_1, X_2, \dots$ *satisfies the condition*

$$\sum_{k=1}^{\infty} \frac{\operatorname{Var}\{X_k\}}{k^2} < +\infty,$$

then it obeys the strong law of large numbers.

The existence of the expectation is a necessary and sufficient condition for the strong law of large numbers to apply to a sequence of independent identically distributed random variables.

► **Central limit theorems.** A random variable X_n with distribution function F_{X_n} is *asymptotically normally distributed* if there exists a sequence of pairs of real numbers m_n, σ_n^2 such that the random variables $(X_n - m_n)/\sigma_n$ converge in probability to a standard normal variable. This occurs if and only if the limit relation

$$\lim_{n\to\infty} P(m_n + a\sigma_n < X_n < m_n + b\sigma_n) = \Phi(b) - \Phi(a),$$

where $\Phi(x)$ is the distribution function of the standard normal law (M14.2.4.1), holds for any a and b $(b > a)$.

LYAPUNOV'S CENTRAL LIMIT THEOREM. *If* $X_1, \dots, X_n, \dots$ *is a sequence of independent random variables having finite expectation values* $E\{X_k\}$ *and finite variances* $\operatorname{Var}\{X_k\}$ *and satisfying Lyapunov's condition*

$$\lim_{n\to\infty} \frac{\sum_{k=1}^{n} \alpha_3(X_k)}{\sqrt{\sum_{k=1}^{n} \operatorname{Var}\{X_k\}}} = 0,$$

where $\alpha_3(X_k)$ *is the third initial moment of the random variable* X_k*, then the sequence of random variables*

$$Y_n = \frac{\sum_{k=1}^{n} (X_k - E\{X_k\})}{\sqrt{\sum_{k=1}^{n} \operatorname{Var}\{X_k\}}}$$

converges in distribution to the normal law, i.e., the following limit exists:

$$\lim_{n\to\infty} P\left(\frac{\sum_{k=1}^{n}(X_k - E\{X_k\})}{\sqrt{\sum_{k=1}^{n}\operatorname{Var}\{X_k\}}} < t\right) = \frac{1}{\sqrt{2\pi}}\int_{-\infty}^{t} e^{-u^2/2}\,du = \Phi(t).$$

LINDEBERG'S CENTRAL LIMIT THEOREM. *Let $X_1, X_2, \ldots$ be a sequence of independent identically distributed random variables with finite expectation $E\{X_k\} = m$ and finite variance σ^2. Then, as $n \to \infty$, the random variable $\frac{1}{n}\sum\limits_{k=1}^{n} X_k$ has an asymptotically normal probability distribution with parameters $(m, \sigma^2/n)$.*

Let μ_n be the number of occurrences of an event A (the number of successes) in n independent trials, and let $p = P(A)$ denote the probability of the occurrence of the event A (the probability of success) in each of the trials. Then the sequence of relative frequencies μ_n/n has an asymptotically normal probability distribution with parameters $(p,\ p(1-p)/n)$.

Part II

Physics

Chapter P1

Physical Foundations of Mechanics

Preliminary remarks. *Mechanical motion* is change in the location of a body with respect to other bodies. This definition implies that mechanical motion is relative. In order to describe motion, one should specify a *frame of reference*, which includes a body of reference, a coordinate system fixed relative to the body, and a set of clocks synchronized with one another. Mechanics studies motions of model objects, a point particle (or a point mass) and a rigid body. The location of these objects is determined by a finite set of independent parameters; the objects are said to have finitely many *degrees of freedom*. *Kinematics* deals with the characterization of motion without finding out its reasons.

P1.1. Kinematics of a Point

P1.1.1. Basic Definitions. Velocity and Acceleration

► **Point particle. Law of motion. Path, distance and displacement.** A body whose dimensions can be neglected in studying its motion (compared to the distances of its movement) is called a *point particle* (or just a *particle*). The position of a point particle at an instant of time t is determined by the *position vector* $\mathbf{r}$ from the origin of some reference frame to the particle (see Fig. P1.1). As the particle moves, the end of the position vector traces a spatial curve, a *path* (also called a *trajectory*). In a rectangular Cartesian reference frame, the position vector is determined by its projections onto the coordinate axis, its x-, y-, and z-coordinates. The motion of a particle is completely determined by specifying its *law of motion*, a single vector function $\mathbf{r}(t)$ or three scalar functions $x(t)$, $y(t)$, $z(t)$. A position vector (or any other vector) can be conveniently written in terms of its projections using unit vectors, $\mathbf{i}$, $\mathbf{j}$, and $\mathbf{k}$, of the respective coordinate axes as follows: $\mathbf{r} = x\mathbf{i} + y\mathbf{j} + z\mathbf{k}$. The *distance* traveled by the particle in a given time interval is measured along the curvilinear path. Distance is a scalar quantity; it is nonnegative and nondecreasing with time. The *displacement* of a particle is the vector $\Delta\mathbf{r} = \mathbf{r} - \mathbf{r}_0$ that connects an original position of the particle with a final one and is equal to the difference of the position vectors at the initial and final time.

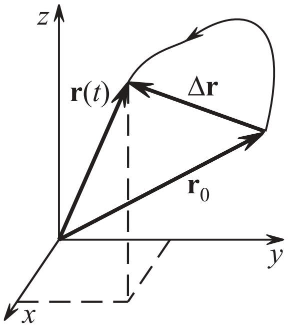

Figure P1.1. Path and displacement.

► **Velocity.** The (instantaneous) *velocity* of a particle is the derivative of its position vector with respect to time:

$$\mathbf{v} = \frac{d\mathbf{r}}{dt}.$$

The velocity is tangent to the path. The (time) average velocity over a finite time interval Δt is defined as the ratio of the displacement to the time interval, $\mathbf{v}_{\text{ave}} = \Delta\mathbf{r}/\Delta t$. (The mean speed is equal to the ratio of the distance traveled to the time interval.) Motion is called *uniform* if $\mathbf{v} = \text{const}$. A uniform motion is a motion along a straight line. A *uniform motion along a given curvilinear path* is a motion with a constant velocity magnitude. (An example of such a motion is a uniform motion in a circle.)

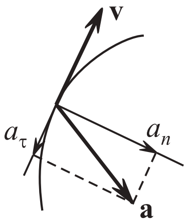

Figure P1.2. Normal and tangential acceleration.

► **Acceleration.** The *acceleration* of a particle is the derivative of the velocity with respect to time:

$$\mathbf{a} = \frac{d\mathbf{v}}{dt}.$$

The vector of acceleration lies in the same plane as the portion of the path where the motion takes places and is directed "inward" the path (if the path is a straight line, the acceleration is directed along it). The projection of the acceleration on the velocity direction is called the *tangential acceleration* and denoted a_τ; it defines the rate at which the velocity magnitude changes with time and equals its time derivative, $a_\tau = dv/dt$. The other component of the acceleration, which is perpendicular to the velocity, is called the *normal acceleration* (Fig. P1.2) and denoted a_n; it characterizes the rate at which the velocity direction changes and equals $a_n = v^2/R$, where R is the radius of curvature of the path (i.e., the radius of the circle that is the best approximation to the path at the given point). The average acceleration over a time interval Δt is defined as $\mathbf{a}_{\text{ave}} = \Delta\mathbf{v}/\Delta t$. A motion is said to be *uniformly accelerated* if $\mathbf{a} = \text{const}$. A *uniformly accelerated motion along a given trajectory* is a motion with $a_\tau = \text{const}$.

P1.1.2. The Direct and Inverse Problems of Kinematics

► **Direct problem.** The problem of determining the characteristics of a motion for a given law of motion is called the *direct problem of kinematics*.

Example 1. Let the law of motion of a particle be given by $x = R\cos\omega t$ and $y = R\sin\omega t$. Find the trajectory equation, velocity, and acceleration of the particle.

Solution. Eliminating time (by making use of the identity $\sin^2\omega t + \cos^2\omega t = 1$) gives the trajectory equation: $x^2 + y^2 = R^2$ (a circle of radius R). Further,

$$\begin{aligned} v_x &= \frac{dx}{dt} = -\omega R\sin\omega t, \\ v_y &= \frac{dy}{dt} = \omega R\cos\omega t \end{aligned} \qquad \text{(velocity components)},$$

$$\left.\begin{aligned} a_x &= \frac{d^2x}{dt^2} = -\omega^2 R\cos\omega t,\\ a_y &= \frac{d^2y}{dt^2} = -\omega^2 R\sin\omega t \end{aligned}\right. \qquad \text{(acceleration components).}$$

The magnitude of the velocity, $v = \sqrt{v_x^2 + v_y^2} = \omega R$, and magnitude of the acceleration, $a = \omega^2 R$, are independent of time and are related by $a = v^2/R$. The acceleration is perpendicular to the velocity and directed towards the center of the circle: $\mathbf{a} = -\omega^2\mathbf{r}$.

► **Inverse problem.** The problem of determining the law of motion for a given acceleration $\mathbf{a}(t)$ is called the *inverse problem of kinematics*. For unique solvability of this problem, one needs to know the *initial conditions*—the position and the velocity of the particle at an initial instant of time.

Example 2. Uniformly accelerated motion. Given the acceleration $\mathbf{a}$ = const of a particle and its initial velocity $\mathbf{v}_0$ and initial position $\mathbf{r}_0$, find the trajectory and the law of motion of the particle.

Solution. Integrating the relation $\frac{d}{dt}\mathbf{v} = \mathbf{a}$ gives the velocity: $\mathbf{v} = \mathbf{v}_0 + \int_0^t \mathbf{a}\,dt = \mathbf{v}_0 + \mathbf{a}t$. Integrating $\frac{d}{dt}\mathbf{r} = \mathbf{v}$ gives the position vector of the particle: $\mathbf{r} = \mathbf{r}_0 + \int_0^t \mathbf{v}\,dt = \mathbf{r}_0 + \mathbf{v}_0 t + \frac{1}{2}\mathbf{a}t^2$.

The particle moves in the plane of the vectors $\mathbf{v}_0$ and $\mathbf{a}$ in a parabola. This becomes apparent in the reference frame where the y-axis is directed along $\mathbf{a}$ and the x-axis is perpendicular to $\mathbf{a}$; we have $x = x_0 + v_{0x}t$ and $y = y_0 + v_{0y}t + \frac{1}{2}at^2$.

► **Other problems.** In the cases where the kinematical problem is neither direct nor inverse and not reduced to a direct or inverse problem, one has to consider a differential equation. Sometimes this equation can be solved by separation of variables.

Example 3. Quite often, when solving dynamical problems, one has to deal with an equation like $dv/dt = -\alpha v^2$ (the body slows down with an acceleration proportional to the velocity squared; α is a constant quantity). Find the speed of the body versus time if its initial value is v_0. Also find the speed versus the displacement s.

Solution. Separating the variables gives $dv/v^2 = -\alpha\,dt$. Integrating the left-hand side from v_0 to v and the right-hand side from 0 to t, one finds $v^{-1} - v_0^{-1} = \alpha t$, and subsequently $v = v_0/(1 + v_0\alpha t)$. Integrating further, one could find the law of motion $s(t)$ and then, having eliminated t, determine $v(s)$. However, the result can be obtained in an easier way: since $v\,dt = ds$, the original separable equation can be rewritten as $dv/v = -\alpha\,ds$. Integrating gives $\ln(v/v_0) = -\alpha s$, and hence $v = v_0\exp(-\alpha s)$.

P1.1.3. Circular Motion

Motion in a circular path can be described using three angular variables: angle of rotation φ, *angular velocity* $\omega = d\varphi/dt$, and *angular acceleration* $\varepsilon = d\omega/dt$. If angles are measured in radians, then the length of the arc corresponding to the angle φ equals $s = \varphi R$. It follows that

$$v = \omega R, \quad a_\tau = \frac{dv}{dt} = \varepsilon R, \quad a_n = \frac{v^2}{R} = \omega^2 R.$$

In the case of a uniform circular motion, the normal acceleration a_n is sometimes called *centripetal*.

The above formulas for the normal and tangential accelerations can be derived by writing the velocity as $\mathbf{v} = v\boldsymbol{\tau}$, where $\boldsymbol{\tau}$ is the unit vector directed along the velocity. Then we have $\mathbf{a} = (dv/dt)\boldsymbol{\tau} + v(d\boldsymbol{\tau}/dt)$. Here we should take into account that $d\boldsymbol{\tau}/dt = \mathbf{n}(d\varphi/dt) = \mathbf{n}(v/R)$, where $\mathbf{n}$ is the unit vector perpendicular to the velocity and directed along the radius. This holds for an arbitrary path as well, provided that the radius of curvature R and the unit normal direction $\mathbf{n}$ are defined by the relation $d\boldsymbol{\tau} = \mathbf{n}(ds/R)$.

P1.1.4. Relativity of Motion. Addition of Velocities

If the motion of a particle is considered relative to two frames of reference, K and K', whose respective axes remain parallel to each other, then the velocities of the particle in these reference frames, $\mathbf{v}$ and $\mathbf{v}'$, satisfy the following velocity-addition formula at any instant of time:

$$\mathbf{v} = \mathbf{v}' + \mathbf{v}_K, \qquad \text{(P1.1.4.1)}$$

where $\mathbf{v}_K$ is the velocity of the reference frame K' relative to K. The accelerations satisfy a similar addition formula: $\mathbf{a} = \mathbf{a}' + \mathbf{a}_K$.

P1.2. Kinematics of a Rigid Body

P1.2.1. Translational and Rotational Motion. Plane Motion

► **Rigid body. Translational and rotational motion**. In mechanics, a *rigid body* is an idealized body the distance between any two points of which does not change (i.e., there is no deformation). Special attention is paid to the description of two simple kinds of motion of a rigid body: translational and rotational. In *translational motion*, the segment connecting any two points of the body moves parallel to itself at all times. Since all points of the body move in the same manner, it suffices to describe the motion of a single point only. In *rotational motion*, all points of the body move in circular paths whose centers lie on the same straight line, called the *axis of rotation*, and the velocities of all points are perpendicular to it. The angular velocities of all points are the same at any instant of time; therefore, it is convenient to introduce a common *vector of angular velocity* $\boldsymbol{\omega}$, directed along the axis of rotation following the right-hand rule. The distribution of linear velocities of points of the body is expressed using cross product*

$$\mathbf{v} = \boldsymbol{\omega} \times \mathbf{r}, \qquad \text{(P1.2.1.1)}$$

where the positions vectors are drawn from any point at the axis of rotation. If the axis of rotation is fixed, the vector of angular acceleration, $\boldsymbol{\varepsilon} = d\boldsymbol{\omega}/dt$, is also directed along the axis.

► **Plane motion of a rigid body.** Plane motion of a rigid body is defined as motion in which the velocities of all points of the body are parallel to some plane. If there is a translationally moving reference frame associated with an arbitrary point of the body (or its imaginary continuation), then the relative motion of any other point will be purely rotational about a fixed axis perpendicular to the plane of motion.

Example. Wheel rolling without slipping on a flat surface with a speed v is convenient to represent as the combination of a translation motion with the speed v and a rotational motion with an angular velocity ω (Fig. P1.3). The velocity of any point of the wheel relative to the surface can be found by the velocity-addition law (P1.1.4.1). The speed of the lowest point O' must be zero; it follows that v and ω are related by $v = \omega R$. The accelerations of all points are directed toward the wheel center.

P1.2.2. Instantaneous Axis of Rotation. Addition of Angular Velocities. Motion Relative to a Rotational Frame

► **Instantaneous axis of rotation.** If some point of a body (or its imaginary continuation) is at rest at some instant, then there exists a straight line that passes through this point and is at rest at this instant. This straight line is called an *instantaneous axis of rotation*. The velocity distribution at the instant in question is given by (P1.2.1.1). The instantaneous axis and $\boldsymbol{\omega}$ can change their position both in space and relative to the body. In particular, the velocities of all points of the wheel in the above example can be obtained as the result of pure rotation about the instantaneous axis through contact point O'. The angular acceleration $\boldsymbol{\varepsilon}$ can be nonparallel to the instantaneous axis.

---

* This equation is a special case of the important mathematical formula $d\mathbf{A}/dt = \boldsymbol{\omega} \times \mathbf{A}$ expressing the time derivative of any vector $\mathbf{A}$ rotating with an angular velocity $\boldsymbol{\omega}$.

$\mathbf{v}_{\text{rot}}$
O′
$\mathbf{v}_{\text{rot}}$
v

Figure P1.3. Rolling of a wheel can be represented as the sum of its translational and rotational motions or as a pure rotation about the instantaneous axis O'.

► **Motion of a rigid body with a fixed point. Addition of angular velocities.** The motion of a rigid body with a fixed point is, at any instant of time, pure rotation about an instantaneous axis. If this motion can be represented as rotation with an angular velocity $\boldsymbol{\omega}_2$ relative to a reference frame rotating with an angular velocity $\boldsymbol{\omega}_1$, then the resulting angular velocity equals $\boldsymbol{\omega} = \boldsymbol{\omega}_1 + \boldsymbol{\omega}_2$. To prove this, one should generalize the velocity-addition law (P1.1.4.1) to nontranslational motion of the reference frame:

$$\mathbf{v} = \mathbf{v}_{\text{rel}} + \mathbf{v}_{\text{transl}}, \tag{P1.2.2.1}$$

where $\mathbf{v}_{\text{transl}}$ is the *translatory velocity* of the moving reference frame at the point considered. If the reference is rotating, we have

$$\mathbf{v} = \mathbf{v}_{\text{rel}} + \boldsymbol{\omega}_1 \times \mathbf{r}. \tag{P1.2.2.2}$$

If the relative motion is pure rotation, $\mathbf{v}_{\text{rel}} = \boldsymbol{\omega}_2 \times \mathbf{r}$, then $\mathbf{v} = \boldsymbol{\omega}_1 \times \mathbf{r} + \boldsymbol{\omega}_2 \times \mathbf{r} = (\boldsymbol{\omega}_1 + \boldsymbol{\omega}_2) \times \mathbf{r}$ and so the resulting motion is rotation with the angular velocity $\boldsymbol{\omega}_1 + \boldsymbol{\omega}_2$.

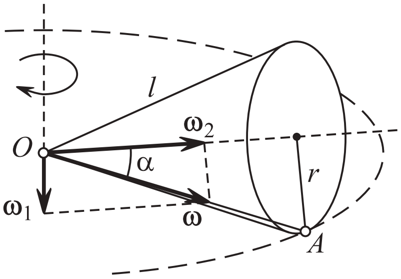

Figure P1.4. A cone rolls on a plane. The sum of the rotational motions is a pure rotation about the axis OA.

Example. A circular cone with a semi-apex angle α is put on its side and rolled without sliding so that its axis rotates with an angular velocity $\boldsymbol{\omega}_1$ (Fig. P1.4). Find the total angular velocity and angular acceleration of the cone.

Solution. In the rotating reference frame where the cone axis is at rest, the cone rotates about this axis with an angular velocity $\boldsymbol{\omega}_2$. The relation between ω_1 and ω_2 can be found from the condition that the point A is at rest; we have $\omega_1 l = \omega_2 r$, or $\omega_1 = \omega_2 \sin\alpha$. It follows that the vector $\boldsymbol{\omega} = \boldsymbol{\omega}_1 + \boldsymbol{\omega}_2$ is horizontal and directed along the line of contact between the cone and the surface; this line is, of course, the instantaneous axis of rotation. The angular acceleration is contributed by only the rotation of the vector $\boldsymbol{\omega}_2$ with the angular velocity $\boldsymbol{\omega}_1$, so that $\boldsymbol{\varepsilon} = d\boldsymbol{\omega}/dt = \boldsymbol{\omega}_1 \times \boldsymbol{\omega}_2$ and $\varepsilon = \omega_1\omega_2 \cos\alpha$.

Formula (P1.2.2.2) is a special case of the formula for the time derivative of an arbitrary vector $\mathbf{A}$:

$$\frac{d\mathbf{A}}{dt} = \left(\frac{d\mathbf{A}}{dt}\right)_{\text{rel}} + \boldsymbol{\omega} \times \mathbf{A}, \tag{P1.2.2.3}$$

where the first term denotes the rate of change of $\mathbf{A}$ relative to the rotating reference frame (see also the footnote to formula (P1.2.1.1)).

In studying motion in noninertial reference frames (see Subsection P1.8.3), we will need the relation between the accelerations of a particle in a fixed reference frame and a rotating one. This relation can be obtained by applying (P1.2.2.3) to either term in (P1.2.2.2):

$$\frac{d\mathbf{v}}{dt}=\frac{d\mathbf{v}_{\rm rel}}{dt}+\boldsymbol{\omega}\times\frac{d\mathbf{r}}{dt}=\left(\frac{d\mathbf{v}_{\rm rel}}{dt}\right)_{\rm rel}+\boldsymbol{\omega}\times\mathbf{v}_{\rm rel}+\boldsymbol{\omega}\times(\mathbf{v}_{\rm rel}+\boldsymbol{\omega}\times\mathbf{r})=\mathbf{a}_{\rm rel}+2\boldsymbol{\omega}\times\mathbf{v}_{\rm rel}+\boldsymbol{\omega}\times(\boldsymbol{\omega}\times\mathbf{r}).$$

The last term, $\boldsymbol{\omega}\times(\boldsymbol{\omega}\times\mathbf{r})$, is the translatory acceleration of the reference frame at the given point (radial or centripetal). Note that along with the relative and translatory accelerations, an additional term arises here. This term, $2\boldsymbol{\omega}\times\mathbf{v}_{\rm rel}$, is called the *Coriolis acceleration*.

P1.3. Dynamics

P1.3.1. Newton's First Law. Mass. Momentum. Force

► **Newton's first law**. Newton's first law states that there are reference frames in which a body not interacting with other bodies is either at rest or in motion in a straight line with constant speed. The reference frames postulated by this law are called *inertial*.

It follows from the velocity-addition law that any reference frame that moves with a constant velocity relative to an inertial reference frame is also inertial. A heliocentric reference frame, related to the Sun and distant stars, can be considered inertial virtually exactly. The Earth can be treated as an inertial reference frame only approximately—the acceleration of the points at its surface amounts to $0.034\,\mathrm{m/s^2}$ due to Earth's daily rotation. In addition, the Earth orbits the Sun but the associated acceleration is three orders of magnitude lower (check this as an exercise).

► **Mass. Momentum**. From Newton's first law it follows that in inertial reference frames, a body's acceleration results from interaction of the body with other bodies. This acceleration depends on the *inertia* of the body, or its ability to resist a change in velocity, and also on the intensity and direction of action of other bodies.

The *mass* of a body, m, is a positive scalar quantity that characterizes the body's inertia. It follows from experiments that when two bodies interact with each other, their accelerations in an inertial reference frame, $\mathbf{a}_1$ and $\mathbf{a}_2$, are opposite to each other in direction and the ratio of their magnitudes, a_1/a_2, is independent of the character and intensity of the interaction. This makes it possible to define the ratio of two masses as the reciprocal of the ratio of the accelerations resulting from the interaction of the bodies: $m_1/m_2=a_2/a_1$. In order to express mass numerically, one has to choose a mass unit. In the International System of Units (SI), the unit of mass is the *kilogram* (kg). Mass possesses the property of additivity: if a body is divided into a number of parts, the sum of masses of all parts equals the mass of the whole body. However, the theory of relativity shows that this property is only valid approximately—it is violated if there is strong interaction between parts of the body. For example, the mass of a nucleus turns out to be less than the sum of masses of its constituting nucleons.

The *momentum* (also referred to as *linear momentum*) of a particle is a vector quantity that equals the product of the mass of the particle by its velocity:

$$\mathbf{p}=m\mathbf{v}. \qquad \text{(P1.3.1.1)}$$

Definition (P1.3.1.1) applies only if $v\ll c$, where c is the speed of light. A more general definition that is valid for any $v<c$ is introduced in the theory of relativity.

► **Force.** A force acting on a body of mass m interacting with another body is the vector quantity $\mathbf{F} = m\mathbf{a}$, where $\mathbf{a}$ is the acceleration imparted by this force to the body m in an inertial reference frame. The more general definition is $\mathbf{F} = d\mathbf{p}/dt$. In Newtonian mechanics, both definitions are equivalent. However, in the theory of relativity, only the latter is valid. In SI, force is measured in *newtons* (*N*); $1\,\mathrm{N} = 1\,\mathrm{kg\,m/s^2}$.

The change of momentum in a time interval Δt, from time 0 to t, under the action of a force $\mathbf{F}$ equals the integral $\Delta\mathbf{p} = \mathbf{p}(t) - \mathbf{p}(0) = \int_0^t \mathbf{F}\,dt$. This quantity is called the *impulse* produced by the force F in the time interval Δt. The average force equals $\mathbf{F}_{\mathrm{ave}} = \Delta\mathbf{p}/\Delta t$.

P1.3.2. Newton's Second and Third Laws

► **Newton's second law.** If a particle is acted upon by N bodies with forces $\mathbf{F}_1, \dots, \mathbf{F}_N$, then the particle acquires an acceleration $\mathbf{a}$ determined by the *vector sum of the forces*:

$$\mathbf{a} = \frac{\mathbf{F}}{m} = \frac{1}{m}\sum_{j=1}^{N}\mathbf{F}_j \qquad \text{or} \qquad \frac{d\mathbf{p}}{dt} = \sum_{j=1}^{N}\mathbf{F}_j.$$

The vector $\mathbf{F} = \sum_{j=1}^{N}\mathbf{F}_j$ is called the *net force* (also known as the *resultant force*) of the forces $\mathbf{F}_1, \dots, \mathbf{F}_N$. Newton's second law is an *equation of motion* of a particle, since it allows (in principle) the calculation of the motion of the particle if the net force applied is a known function of time and the particle position (and velocity). Likewise, given a system of particles, the set of Newton's second laws for each of them allows the calculation of the motion of the particles if the forces applied are known functions of time and mutual positions of the particles.

Outlined below are the properties of forces that are useful in solving mechanical problems.

► **Newton's third law** states that the forces $\mathbf{F}_{AB}$ and $\mathbf{F}_{BA}$ with which two bodies, A and B, act upon each other are directed along the same straight line, opposite in direction, and equal in magnitude:

$$\mathbf{F}_{AB} = -\mathbf{F}_{BA}.$$

P1.3.3. Action at a Distance. Causality. Natural Forces

► **Action at a distance. Causality. Field.** In Newtonian mechanics, Newton's third law is considered to hold regardless of the nature of interaction and of whether the bodies are in direct contact with each other or interact at a distance by means of gravitational or electromagnetic forces. However, the validity of Newton's third law for long-range forces would mean instantaneous transmission of information about changes in body positions. The notion of long-range action contradicts the postulates of the theory of relativity, which forbids information transmission at speeds faster than the speed of light. Modern physics has rejected the use of the concept of action at a distance. Instead, it has introduced a new participant—a *force field* (e.g., gravitational, electric, etc.) that fills the whole of space. A particle at a given point in space is acted upon not by distant bodies but by a field in the vicinity of the point; this field is produced by distant bodies (*field sources*). A change in the field is transmitted from point to point and propagates with a final speed (speed of light). Newtonian mechanics is valid in low-speed approximation, $v \ll c$, and in this, *nonrelativistic limit*, one can use both action at a distance and field.

It is convenient to study motion of a particle (or a system of particles) in an *external stationary field* generated by sources at rest (e.g., Earth's gravitational field). A force field is called *central* if the force exerted by the field on a particle placed in it is directed toward a single point called the *field origin* (*force center*) and the magnitude of the force depends only on the distance r to the origin, so that

$$\mathbf{F}(\mathbf{r}) = F_r(r)\frac{\mathbf{r}}{r},$$

where $F_r(r)$ is the projection of the force onto the radial direction; $F_r > 0$ corresponds to repulsive forces and $F_r < 0$ corresponds to attractive forces. A field is called *uniform* in a region of space if this force is the same (in direction and magnitude) at every point of space: $\mathbf{F} = \text{const}$.

► **Natural forces**. The whole diversity of naturally occurring forces can be reduced to a few fundamental types of interaction: gravitational, weak, electromagnetic, and strong. However, for practical purposes, this approach is unsuitable. Apart from the fundamental long-range forces (gravitational force in mechanics), one needs to know properties of various forces arising when macroscopic bodies are in contact with one another. Below is the list of forces arising in solving mechanical problems.

1. *Gravitational force* $m\mathbf{g}$ (the force with which a body at the Earth's surface is pulled to the Earth's center).

2. *Elastic force*. When a body is deformed in a certain direction, the restoring elastic force is proportional to the deformation (*Hooke's law*): $F_\text{e} = k|\Delta l|$, where k is the spring constant (body stiffness) and Δl is the deformation in this direction. The spring constant of an elastic rod is proportional to its cross-sectional area and inversely proportional to its length, so that

$$F_\text{e} = ES\frac{|\Delta l|}{l},$$

where E is *Young's modulus*, which depends on the rod material. In the limit of infinitely large stiffness, the (normal) reaction force N and the string tension force T arise; these forces are determined from the equations of motion. Such forces are called *constraint reaction forces* or *constraint reactions*.

3. *Dry friction force*. Sliding friction force: $F_\text{fr} = \mu_1 N$, where μ_1 is the sliding friction coefficient. Static friction force: $F_\text{fr} \le \mu_2 N$, where μ_2 is the static friction coefficient. It is usually assumed that $\mu_1 = \mu_2$ in solving problems. The static friction force is also a constraint reaction.

4. *Drag force*. Drag refers to forces that oppose the relative motion of a body through a liquid or gas. It depends on the relative speed and the transverse size of the body. For low relative speeds and small sizes, the drag force is proportional to the speed (viscous drag). For large relative speeds, the drag force is proportional to the cross-sectional area and the speed squared (head-on drag or quadratic drag).

P1.3.4. Galilean Relativity Principle

Galilean relativity (also known as *Galilean invariance*) is a principle that states that all laws of mechanics are the same in all inertial reference frames. Suppose a frame K' moves relative to a frame K with a constant velocity $\mathbf{V}$. Let the respective axes of the two frames be parallel to each other and let the x- and x'-axes be directed along $\mathbf{V}$ (Fig. P1.5). Also let time be counted off from the instant when the frames coincide. Then the coordinates and time in the frame K' are expressed in terms of those in the frame K using the *Galileo transformations*

$$x' = x - Vt, \qquad y' = y, \qquad z' = z, \qquad t' = t. \tag{P1.3.4.1}$$

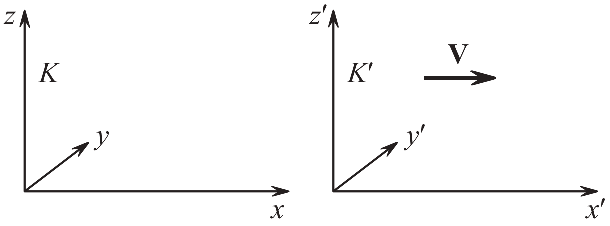

Figure P1.5. Two inertial reference frames. The mechanical laws have the same form in both frames.

Under the Galileo transformations, the difference of the velocities of two particles as well as the distance between them remain unchanged; this means that the forces acting between the two particles also remain the same. Furthermore, the Galileo transformations do not change the accelerations of the particles. Consequently, both sides of the equation of Newton's second law remain unchanged. So the equation of motion has the same form in various reference frames (*invariance under the Galileo transformations*).

The Galileo transformations are based on the assumption that the course of time and the lengths of segments are independent of the reference frame, which were considered to be inherent properties of space and time. The theory of relativity revises the traditional view of space and time and shows that the Galileo transformations are valid for $V \ll c$. The more general transformations are the Lorenz transformations, which are valid for any $V < c$.

P1.4. Law of Conservation of Momentum

P1.4.1. Center of Mass. Momentum of a System of Particles

► **System of particles. Center of mass.** Consider a system of N particles. The forces acting on a jth particle can be divided into *internal* ones, $\mathbf{F}^{\rm i}_{jk}$, exerted by the other particles, and *external* ones, the resultant of which will be denoted $\mathbf{F}^{\rm e}_{j}$. According to Newton's third law, the sum of the internal forces is zero. Hence, the sum of all forces acting on the system equals the sum of external forces. If the particles do not interact with external bodies, then the system is called *closed* (or *isolated*).

The *center of mass* (or *center of inertia*) of a system of N particles with masses $m_1, \ldots, m_N$ and position vectors $\mathbf{r}_1, \ldots, \mathbf{r}_N$ is the point whose position is defined by the vector

$$\mathbf{r}_{\rm cm} = \frac{m_1\mathbf{r}_1 + \cdots + m_N\mathbf{r}_N}{m_1 + \cdots + m_N}. \qquad \text{(P1.4.1.1)}$$

A translationally moving reference frame with origin at the center of mass is called a *center-of-mass frame*.

If the mass of a system is distributed continuously (in space, on surface, or along a line), the system can be mentally divided into a large number of small regions to represent particles. Further, passing to a limit, one can replace summation by integration. The distribution of mass over volume is defined using *mass density* (or simply *density*), $\rho(\mathbf{r})$, such that $dm = \rho(\mathbf{r})\,dV$. Then, for continuously distributed mass, the definition of the center of mass (P1.4.1.1) becomes

$$\mathbf{r}_{\rm cm} = \frac{\int \mathbf{r}\rho(\mathbf{r})\,dV}{\int \rho(\mathbf{r})\,dV}.$$

A body with constant density across the whole volume is called a *uniform body*.

► **Momentum.** The momentum of a system of particles is defined as the sum of momenta of the constituting particles:

$$\mathbf{p} = \sum \mathbf{p}_j.$$

Differentiating equation (P1.4.1.1) with respect to time, one can find that the momentum of the system is expressed in terms of the center-of-mass velocity as

$$\mathbf{p} = m\mathbf{v}_{\text{cm}}, \tag{P1.4.1.2}$$

where m is the total mass of the system. It follows that the momentum of a system of particles equals zero in a center-of-mass frame.

Summing up the Newton's Second Law equations for each particle, $d\mathbf{p}_j/dt = \mathbf{F}_j$, and taking into account that the internal forces are canceled out, one obtains

$$\frac{d\mathbf{p}}{dt} = \sum \mathbf{F}_j^{\text{e}} \tag{P1.4.1.3}$$

This means that the rate of change of the momentum of the system equals the net external force.

P1.4.2. Law of Conservation of Momentum. Motion of Center of Mass

► **Law of conservation of momentum.** From equation (P1.4.1.3) it follows that the *momentum of a closed system is conserved*. The law of conservation of (linear) momentum is a consequence of uniformity of space (there is no distinguished point in space) and is therefore a fundamental law of nature. Although derived within the scope of Newtonian mechanics, this law remains valid beyond it. Even with allowance for a finite speed of signal propagation, which leads to violation of Newton's third law, the law of conservation of momentum is obeyed exactly, provided that the momentum of the transmitter (force field) is taken into account.

The *momentum of an unclosed system* is conserved in the following cases:

1. The net external force is zero.
2. The net external force is perpendicular to some direction. Then the projection of momentum on this direction (not the whole momentum) is conserved.
3. If the interaction last a very short time Δt and the net external force $\mathbf{F}^{\text{e}}$ is bounded,* then the change in the momentum of the system, $\mathbf{F}^{\text{e}}\Delta t$, can be neglected (effectively assuming that $\Delta t \to 0$).

► **Motion of center of mass**. On differentiating equation (P1.4.1.2) with respect to time and taking into account (P1.4.1.3), we arrive at the equation of motion of the center of mass

$$m\mathbf{a}_{\text{cm}} = \sum \mathbf{F}_j^{\text{e}}. \tag{P1.4.2.1}$$

It follows that the center of mass moves in the same manner as though it was a single particle, whose mass is equal to the mass of the system, moving under the action of the net external force.

---

* Under these conditions, the momenta of particles can change considerably under the action of large internal forces (explosion, impact, etc.).

Example. A thin rod of length l and mass m rotates in a horizontal plane about one of its ends with an angular velocity ω. Find the tension force at the middle of the rod.

Solution. The center of mass of the outer half of the rod moves in a circle of radius $\frac{3}{4}l$ under the action of a single force, the unknown tension force. It follows from equation (P1.4.2.1) that $F = \bigl(\frac{1}{2}m\bigr)\omega^2\bigl(\frac{3}{4}l\bigr) = \frac{3}{8}m\omega^2 l$.

Note that the center of mass of a closed system moves with a constant velocity; hence, a center-of-mass frame is inertial.

► **Spacecraft propulsion.** For a spacecraft in outer space (far away from gravitating bodies), a change in its velocity is only possible by exhausting part of mass, rocket propellant. The equation of motion of a spacecraft under the action of an external force **F** and a propulsive jet can be easily obtained by writing down Newton's second law in the form (P1.4.1.3) in an inertial frame associated with the spacecraft at the current instant:

$$m\,\Delta\mathbf{v} + \Delta M\,\mathbf{u} = \mathbf{F}\,\Delta t,$$

where **u** is the jet velocity relative to the spacecraft and ΔM is the mass of the propellant exhausted in time Δt. Dividing by Δt, one arrives at the *Meshcherskii equation*:

$$m\mathbf{a} = \mathbf{F} - \mu\mathbf{u},$$

where $\mu = \Delta M/\Delta t = -\Delta m/\Delta t$ is the *propellant use* in the jet. The latter term on the right-hand side is called the *propulsive force*.

Let us write the Meshcherskii equation for the case of motion in a straight line with no external force applied to obtain $m(dv/dt) = -(dm/dt)u$. Assuming that u is constant and denoting the initial mass of the spacecraft by m_0, we find how the speed of the spacecraft depends on its mass: $v/u = -\ln(m/m_0)$ (*Tsiolkovsky equation*).

P1.5. Law of Conservation of Energy

P1.5.1. Work and Power. Kinetic Energy

► **Mechanical work** is a scalar quantity that is a measure of change in energy. The *work of external forces equals the change in energy*:

$$A = E_2 - E_1. \qquad \text{(P1.5.1.1)}$$

Based on this equation, we will define different kinds of energy. (A refinement of this principle will be given in Chapter P2.)

The work of a force on a small portion of a path is defined as the dot product of the force by the displacement: $\delta A = \mathbf{F}\cdot d\mathbf{r}$. The work on the whole path from position 1 to position 2 equals

$$A = \int_1^2 \mathbf{F}\cdot d\mathbf{r} = \int_1^2 F_\tau\,|d\mathbf{r}| = \int_1^2 F\,|d\mathbf{r}|\cos\alpha,$$

where F_τ is the projection of the force on the direction of motion of the point where the force is applied and α is the angle between the force and this direction. In SI, work and energy are measured in *joules* (*J*) (1 J = 1 N m).

Example 1. The work of a constant force **F**,

$$A = \int_1^2 \mathbf{F}\cdot d\mathbf{r} = \Bigl(\mathbf{F}\cdot\int_1^2 d\mathbf{r}\Bigr) = \mathbf{F}\cdot(\mathbf{r}_2 - \mathbf{r}_1),$$

equals the dot product of the force by the total displacement and is independent of the path of the point at which the force is applied.

Example 2. The work of a central force, the force exerted by a central field (see Subsection P1.3.3), equals

$$A = \int_1^2 \mathbf{F} \cdot d\mathbf{r} = \int_{r_1}^{r_2} F_r(r)\, dr.$$

It has been taken into account that the projection of $d\mathbf{r}$ onto the radial direction is equal to the change in the distance r to the origin. The work depends only on the initial, r_1, and final, r_2, distance to the origin and is independent of the path.

► **Mechanical power** is the rate at which work is performed. The average power is the ratio of the work done to the time interval. The instantaneous work equals the time derivative of the work done:

$$P = \frac{dA}{dt} = \frac{\mathbf{F} \cdot d\mathbf{r}}{dt} = \mathbf{F} \cdot \mathbf{v} = F_\tau v.$$

Power is measured in *watts* (*W*): 1 W = 1 J/s.

► **Kinetic energy.** The kinetic energy of a particle is the energy it possesses due to its motion and depending on its speed. The velocity of a particle changes under the action of a net force **F**, the work of which equals

$$A = \int_1^2 F_\tau\, |d\mathbf{r}| = m\int_1^2 a_\tau v\, dt = m\int_1^2 \frac{dv}{dt} v\, dt = m\int_{v_1}^{v_2} v\, dv = \tfrac{1}{2}mv_2^2 - \tfrac{1}{2}mv_1^2. \quad \text{(P1.5.1.2)}$$

It is apparent that, in accordance with the general principle (P1.5.1.1), kinetic energy can be defined as $E_\text{k} = mv^2/2$. The above equation, stating that the change in the kinetic energy equals the work of the net force, is known as the *work-energy theorem*.

The *kinetic energy of a system of particles* is defined as the sum of the kinetic energies of all constituting particles. The change in the kinetic energy of the system equals the work of all forces acting on its particles. The kinetic energy of a system of particles equals

$$E_\text{k} = \frac{mv_\text{cm}^2}{2} + E_\text{rel}, \quad \text{(P1.5.1.3)}$$

where m is the mass of the system, v_cm is the speed of its center of mass, and E_rel is the kinetic energy relative to a center-of-mass frame. Equation (P1.5.1.3) is known as *König's theorem*.

P1.5.2. Conservative Forces. Potential Energy

► **Conservative forces. Potential field.** A force of interaction between two particles is called *conservative* if the work of this force depends on only the initial and final positions of the particles and does not depend on their paths. Forces that do not satisfy this condition are called *nonconservative*.

An external stationary field is called *potential* if its work on moving a particle depends on only its initial and final positions and does not depend on its path. (It is equivalent to say that the work of the field on moving a particle through a closed path is zero.) A potential field is a field of conservative forces; it is generated by fixed external sources. As follows from example 1, a uniform field is potential. From example 2 it follows that any central field is potential. A superposition of several central fields (generated by several sources) is also a potential field. Hence, an electrostatic field and a stationary gravitational field are also potential. From example 2 it also follows that the elastic force produced by a light spring is conservative.

A system of particles with only conservative forces acting between them is referred to as a *conservative system*.

► **Potential energy** is energy stored within a system; it characterizes interaction between particles and depends on their mutual positions. The *potential energy of a particle in an external potential field* is defined as follows. Let us define the *difference between the potential energies* of the particle as the work performed by the field to move the particle from one position to another:

$$E_\mathrm{p}(\mathbf{r}_1) - E_\mathrm{p}(\mathbf{r}_2) = A_{12}. \qquad \text{(P1.5.2.1)}$$

This work is independent of the path. Hence, the *change in the potential energies*, $E_2 - E_1$, equals the *negative* of the work done by the field. If the particle is moved very slowly by an *external* force, then the work performed by the external force is equal in magnitude and opposite in sign to the work of the field, so $A^\mathrm{e}_{12} = E_2 - E_1$ in accordance with the general principle (P1.5.1.1).

Equation (P1.5.2.1) defines the difference of potential energies; so the potential energy is defined up to an additive constant. To make the definition unambiguous, one should specify the value (usually zero) of the potential energy at some point in space.

Example 1. The work done by the force of gravity $m\mathbf{g}$ on lifting a particle of mass m from height h_1 to height h_2 is equal to $mgh_1 - mgh_2$. Consequently, the potential energy of the particle in the gravitational field is $E_\mathrm{p} = mgh$, where the height is counted off from a chosen zero level. The potential energy of a system of points in the field of gravity equals

$$E_\mathrm{p} = \sum_j m_j g h_j = mg\frac{\sum_j m_j h_j}{m} = mgh_\mathrm{cm},$$

where m is the mass of the system and h_cm is the height of its center of mass.

Example 2. The work done by the elastic force equals $\int_{x_1}^{x_2}(-kx)\,dx = \frac{1}{2}kx_1^2 - \frac{1}{2}kx_2^2$, where x_1 and x_2 are the initial and final points of the spring deformation. Consequently, the potential energy of the elastic spring is $E_\mathrm{p} = \frac{1}{2}kx^2$, where zero energy corresponds to the undeformed spring.

Example 3. The work done by friction or resistive forces is negative on each segment of the path and also along a closed path. Consequently, these forces do not satisfy the condition of being conservative and are nonconservative.

The *potential energy of conservative interation* of two particles can be treated as the potential energy of one particle in the field generated by the other. The result is independent of which particle is considered to be the field source.

► **Relation between force and potential energy.** By writing equation (P1.5.2.1) for two close particles lying on the x-axis and separated by a distance dx, one obtains $E_\mathrm{p}(x) - E_\mathrm{p}(x + dx) = F_x\,dx$. It follows that the projection F_x of the force $\mathbf{F}$ onto the x-axis is determined by the derivative of the potential energy:

$$F_x = -\frac{\partial E_\mathrm{p}}{\partial x}. \qquad \text{(P1.5.2.2)}$$

The partial derivative means that E_p is treated as a function of only x here. The same is obviously valid for projections on any other direction. Consequently, the vector of force equals the opposite of the *gradient* of the potential energy:

$$\mathbf{F} = -\left(\frac{\partial E_\mathrm{p}}{\partial x}\mathbf{i} + \frac{\partial E_\mathrm{p}}{\partial y}\mathbf{j} + \frac{\partial E_\mathrm{p}}{\partial z}\mathbf{k}\right) = -\operatorname{grad} E_\mathrm{p}, \qquad \text{(P1.5.2.3)}$$

where $\mathbf{i}$, $\mathbf{j}$, and $\mathbf{k}$ are unit vectors in the x-, y-, and z-axis, respectively.

For central field, formula (P1.5.2.2) becomes

$$F_r = -\frac{dE_\mathrm{p}(r)}{dr}. \qquad \text{(P1.5.2.4)}$$

P1.5.3. Mechanical Energy of a System of Particles. Law of Conservation of Mechanical Energy

► **Mechanical energy.** The mechanical energy of a system of particles is defined as the sum of its kinetic energy, the internal potential energy due to interaction between the particles, and the potential energy in an external field:

$$E_{\text{mech}} = \sum_j \frac{m_j v_j^2}{2} + \sum_{j<n} E_{jn} + \sum_j E_j^{\text{e}}. \tag{P1.5.3.1}$$

According to König's theorem (P1.5.1.3), the kinetic energy of a system equals the sum of two terms, the energy of its motion as a whole, $mv_{\text{cm}}^2/2$, and the kinetic energy in a center-of-mass frame, E_{rel}. The sum of E_{rel} and the potential energy of particle interactions is sometimes called the *internal mechanical energy* of the system.

► **Change in mechanical energy.** The change in the kinetic energy of a system equals the total work of all forces applied to the particles (see equation (P1.5.1.2)). The change in the potential energy equals the negative of the work of the conservative forces and external potential fields. Consequently, the change in the mechanical energy of the system equals the work done by the internal nonconservative forces and all external forces, except for the potential fields, whose contribution is included into E_{mech}. So we have

$$\Delta E_{\text{mech}} = A_{\text{nonconservative}} + A^{\text{e}}. \tag{P1.5.3.2}$$

► **Law of conservation of mechanical energy.** The mechanical energy of a closed conservative system does not change. This statement is a special case of the general fundamental principle of conservation of energy: the *total energy of a closed system is conserved*. Apart from the mechanical energy, the total energy also includes the different kinds of internal energy: thermal, chemical, and nuclear. The general principle of conservation of energy goes far beyond the scope of Newtonian mechanics, within the framework of which the law of conservation of the mechanical energy has been obtained. This principle is in close connection with the fundamental postulate of *uniformity of time* (there is no selected instant in time) and is one of the fundamental principles on which modern physics is based.

Note that if a conservative system is in an external potential field, the mechanical energy is also conserved, provided that the potential energy of the particles in the field is included in it.

The condition for a system to be conservative is equivalent to the requirement that both the mechanical and internal components of the total energy must be conserved individually. If, for example, there are friction forces acting in the system, whose work is negative, then the mechanical energy is reduced (see equation (P1.5.3.2)) being converted into the internal energy; in this case, heat is said to be produced in the system. The mechanical energy can change also in the case where there is a mechanism present in the system that can produce work at the expense of the internal energy (e.g., an internal combustion engine, a human being, etc.).

Example 1. Elastic collision. In a central elastic impact of two balls, both the momentum of the system and its mechanical energy are conserved. If m_1 and m_2 are the masses of the balls, v_1 and v_2 are speeds of the balls before the collision, and u_1 and u_2 are those after the collision, we have

$$m_1 v_1 + m_2 v_2 = m_1 u_1 + m_2 u_2,$$

$$\frac{m_1 v_1^2}{2} + \frac{m_2 v_2^2}{2} = \frac{m_1 u_1^2}{2} + \frac{m_2 u_2^2}{2}.$$

Instead of the second equation, it is more convenient to use the condition that the relative speed of the balls does not change in magnitude but changes in sign: $v_{1x} - v_{2x} = u_{2x} - u_{1x}$. This equation can be derived directly from the first two, but it becomes obvious if we consider the motion in a center-of-mass frame (the relative speed remains the same here). In this frame, the total momentum of the system is zero and the speed of either ball simply reverses after the impact; both conservation laws are obeyed. Then, solving the two linear equations, we find the final speeds of the balls:

$$u_1 = \frac{(m_1 - m_2)v_1 + 2m_2v_2}{m_1 + m_2}, \qquad u_2 = \frac{(m_2 - m_1)v_2 + 2m_1v_1}{m_1 + m_2}.$$

If we replace the second ball with a moving wall ($m_2 \gg m_1$), we get

$$u_1 \approx -v_1 + 2v_2, \quad u_2 \approx v_2.$$

Example 2. Inelastic collision. Two balls of masses m_1 and m_2 with velocities $\mathbf{v}_1$ and $\mathbf{v}_2$ undergo a perfectly inelastic collision such that the balls move as one with a velocity $\mathbf{u}$ after the collision. (No rotation occurs if the impact is central in a center-of-mass frame.) The velocities become equal as a result of nonconservative forces, which means that some heat is released in the impact. This can be verified by finding the final velocity using the law of conservation of momentum, $m_1\mathbf{v}_1 + m_2\mathbf{v}_2 = (m_1 + m_2)\mathbf{u}$, and calculating the decrease in the mechanical energy:

$$\frac{m_1v_1^2}{2} + \frac{m_2v_2^2}{2} - \frac{(m_1 + m_2)u^2}{2} = \frac{m_1m_2}{m_1 + m_2}\frac{(\mathbf{v}_1 - \mathbf{v}_2)^2}{2}.$$

It is even easier to obtain this result considering the motion in a center-of-mass frame, where the balls are at rest after the collision.

P1.5.4. Potential Curves. Stability

If we know the potential energy $E_\mathrm{p}(r)$ of a one-dimensional motion in a potential field (an example is shown in Fig. P1.6), then we can find out the following based on relation (P1.5.2.2):

a) The direction of the force ($F > 0$ for $0 < r < r_\mathrm{min}$ and $r > r_\mathrm{max}$; $F < 0$ for $r_\mathrm{min} < r < r_\mathrm{max}$).

b) The points of equilibrium ($F = 0$ at $r = r_\mathrm{min}$ and $r = r_\mathrm{max}$).

c) Stability of equilibrium. In the vicinity of the point $r = r_\mathrm{min}$, the force is directed toward the point, so the equilibrium is stable. At $r = r_\mathrm{max}$, the equilibrium is unstable. A stable equilibrium corresponds to a minimum of the potential energy.

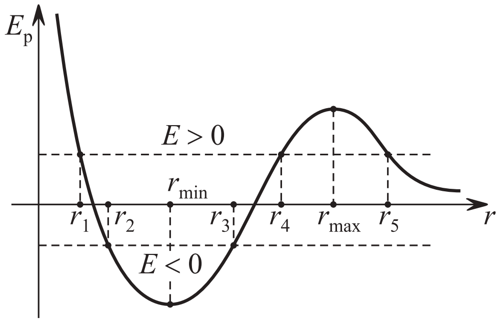

Figure P1.6. Given a potential energy curve, one can determine the direction of the force, the positions of the equilibrium points and their stability, and the character of motion.

d) The character of motion for a given value of the total mechanical energy E. Motion is possible only where $E > E_\mathrm{p}$ (the kinetic energy is nonnegative). If $E < E_\mathrm{p}(\infty)$ (in Fig. P1.6, $E_\mathrm{p}(\infty) = 0$), motion is *finite*, so it can occur in a limited range of r. With $E < 0$ in Fig. P1.6, motion occurs only between the *turning points* r_2 and r_3. For $E > 0$, motion is either *infinite*, where the particle goes to infinity with kinetic energy E after reflecting from the turning point r_5, or locked by a potential barrier, where the particle moves between the turning points r_1 and r_4. In classical mechanics, a potential barrier is impenetrable. In quantum mechanics, there is a nonzero probability that a potential barrier can be penetrated (tunnel effect).

P1.6. Law of Conservation of Angular Momentum

P1.6.1. Moment of Force. Net Force

► **Moment of force.** The moment of a force **F** about a point O is defined as

$$\mathbf{M} = \mathbf{r} \times \mathbf{F}, \tag{P1.6.1.1}$$

where **r** is the vector from O to the point where the force is applied. A moment of force is also called a *torque*. The moment of force does not change if the force is moved along the straight line of its application. The magnitude of the moment of force equals $M = Fr\sin\alpha = Fd$, where α is the angle between the force vector and the radius vector **r**, and d is the distance between the point O and the line of action of the force; the distance d is called the *moment arm* (Fig. P1.7).

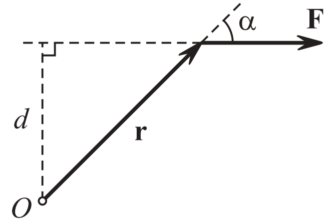

Figure P1.7. The moment of the force **F** is perpendicular to the plane of the figure and directed away from the reader. The magnitude of the moment equals the product of F by the arm d.

The most important property of moment of force is that the sum of the moments of internal forces in an arbitrary system of particles is zero. This fact follows from Newton's third law (see Subsection P1.3.2), since the forces acting between each pair of particles are equal in magnitude, opposite in direction, and directed along the straight line connecting the particles.

Note another property of moment of force: if the sum of forces is zero, then these forces produce the same net moment about any point in space.

► **Net force.** The *net force* of a system of forces is the force that equals the vector sum of them and is applied so that its moment about any point in space equals the net moment of this system of forces.

Example. Compute the net moment of the forces of gravity acting on the particles of a system:

$$\mathbf{M} = \sum \mathbf{r}_j \times m_j\mathbf{g} = \Big(\sum m_j\mathbf{r}_j\Big) \times \mathbf{g} = \mathbf{r}_{\rm cm} \times (m\mathbf{g}),$$

where m is the mass of the system, $\mathbf{r}_{\rm cm}$ is the radius vector of the center of mass. It is apparent that the net force passes through the center of mass; hence, *the center of mass is also the center of gravity*.

The *moment of force about an axis z* is the z-projection, M_z, of the moment of force about any point on the axis. If both **r** and **F** in (P1.6.1.1) are resolved into two components, parallel and perpendicular to the axis z, so that $\mathbf{r} = \mathbf{r}_{\|} + \mathbf{r}_{\perp}$ and $\mathbf{F} = \mathbf{F}_{\|} + \mathbf{F}_{\perp}$, then the components parallel to the axis will not contribute to the projection of the moment onto the axis. It follows that $M_z = (\mathbf{r}_{\perp} \times \mathbf{F}_{\perp})_z$. In the plane perpendicular to the axis, we have the same picture as in Fig. P1.7, except that **r** and **F** must be replaced with $\mathbf{r}_{\perp}$ and $\mathbf{F}_{\perp}$. Accordingly, the magnitude of the moment about an axis is also equal to the product of the force by the moment arm, while the choice of the positive direction along the axis can be replaced with the easier choice of the positive direction of rotation about the axis.

P1.6.2. Angular Momentum of a Particle. Motion in Central Field

► **Angular momentum.** The angular momentum of a particle about a point O is the vector quantity

$$\mathbf{L} = \mathbf{r} \times \mathbf{p}, \tag{P1.6.2.1}$$

where $\mathbf{r}$ is the vector from O to the position of the particle and $\mathbf{p} = m\mathbf{v}$ is the (linear) momentum of the particle. Angular momentum is also known as *moment of momentum*. If the particle moves with a constant velocity, its angular momentum does not change. The magnitude of the angular momentum equals the product of the momentum by the arm. The angular momentum about an axis z is the z-projection, L_z, of the angular momentum $\mathbf{L}$ about any point at the axis. The angular momentum about an axis is determined by the projection of the momentum on a plane perpendicular to the axis: $L_z = (\mathbf{r}_\perp \times \mathbf{p}_\perp)_z$. These properties are similar to those of the moment of force.

The time derivative of the angular momentum of a particle about a point O,

$$\frac{d\mathbf{L}}{dt} = \frac{d\mathbf{r}}{dt} \times \mathbf{p} + \mathbf{r} \times \frac{d\mathbf{p}}{dt} = \mathbf{v} \times \mathbf{p} + \mathbf{r} \times \mathbf{F} = \mathbf{M}, \tag{P1.6.2.2}$$

equals the moment of the net force about O (since $\mathbf{v}$ and $\mathbf{p}$ are parallel to each other, we have $\mathbf{v} \times \mathbf{p} = \mathbf{0}$)

► **Motion in central field.** Since the force acting on a particle in a *central field* (also called a *central-force field*) is directed to the origin of the field, the moment of this force about the origin is identically zero. Hence, the vector angular momentum $\mathbf{L}$ is conserved. It follows from definition (P1.6.2.1) that the motion occurs in one plane perpendicular to $\mathbf{L}$ and the quantity $L = mvr\sin\alpha$ is conserved. The magnitude of the angular momentum is proportional to the rate at which the radius vector $\mathbf{r}$ sweeps out area (Fig. P1.8): $dS/dt = \frac{1}{2}r(v\,dt)\sin\alpha/dt = \frac{1}{2}L/m$. Consequently, the statement that angular momentum is conserved in a central field turns out to be equivalent to *Kepler's second law of planetary motion*.

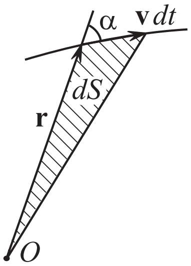

Figure P1.8. The rate at which the radius vector sweeps out area is expressed in terms of the angular momentum.

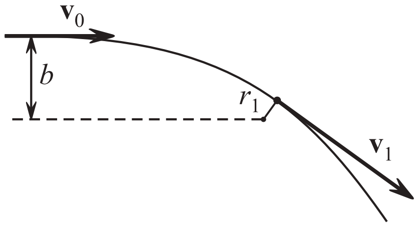

Figure P1.9. Fly-by of a particle near a force field center; b is the aiming parameter.

Example 1. Aiming parameter. Conservation of angular momentum in a central field allows one to relate the aiming parameter b of a particle approaching the field origin from far away (Fig. P1.9) to the distance of closest approach r_1 to the origin. (The *aiming parameter* is the distance from the field origin to the straight line of particle motion in the absence of interaction.) At the instant of closest approach to the origin, the particle velocity is perpendicular to the radius vector, so the law of conservation of angular momentum can be written as

$$mv_0 b = mv_1 r_1,$$

where v_0 is the initial speed of the particle far away from the origin and v_1 is the particle speed at the instant of closest approach. Expressing v_1 and substituting into the law of conservation of energy, $\frac{1}{2}mv_0^2 = \frac{1}{2}mv_1^2 + E_{\rm p}(r_1)$, one can find r_1.

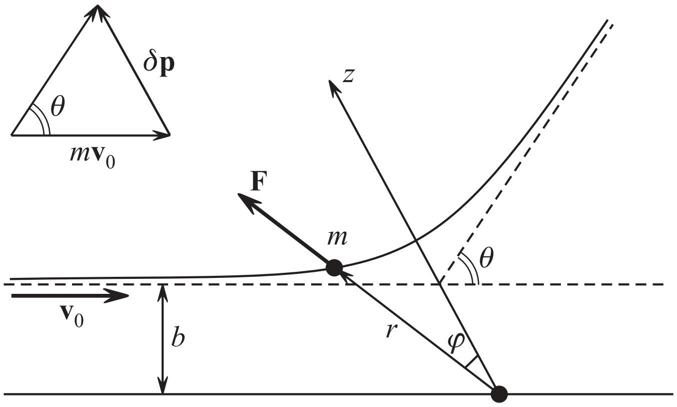

Figure P1.10. To the problem of determining the scattering angle θ in the field $F_r = A/r^2$.

Example 2. Scattering angle. The problem of particle scattering on a Coulomb (or gravitational) center is of significant importance in astrophysics and nuclear physics. Consider a particle of mass m moving toward a (repulsive) force center $F_r = A/r^2$ with the initial kinetic energy $E_\mathrm{k} = \frac{1}{2}mv_0^2$ and aiming parameter b. Find the scattering angle θ.

Solution. From symmetry considerations it is clear that the change in momentum in the whole duration of the motion is directed along the z-axis (see Fig. P1.10) and is equal to

$$|\Delta\mathbf{p}| = \Delta p_z = 2mv_0 \sin(\theta/2).$$

The change in momentum (projected onto the z-axis) in the time dt is

$$dp_z = F_z\,dt = F\cos\varphi\,dt = \frac{A}{r^2}\frac{d\varphi}{v_\varphi/r}\cos\varphi = \frac{mA}{L}\cos\varphi\,d\varphi,$$

where $v_\varphi = r(d\varphi/dt)$ is the azimuthal (perpendicular to the radius vector) velocity component (see Fig. P1.11). The angular momentum of the particle is expressed in terms of v_φ as $L = mv_\varphi r$. Integrating with respect to φ from $-(\pi-\theta)/2$ to $(\pi-\theta)/2$ yields

$$\Delta p_z = \frac{2mA}{L}\cos(\theta/2).$$

Comparing the two expressions of Δp_z and taking into account that $L = mv_0 b$, we find that

$$\tan\frac{\theta}{2} = \frac{A}{2E_\mathrm{k}b}.$$

This formula will be used subsequently in the discussion of Rutherford's experiments.

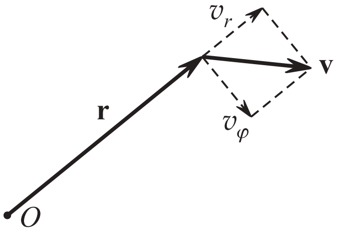

Figure P1.11. Radial and azimuthal components of velocity.

► **Effective potential energy.** With the laws of conservation of energy and angular momentum, one can establish the time dependence of the central distance r by reducing the problem to that of one-dimensional motion. To this end, the particle velocity should be resolved into two mutually perpendicular components (Fig. P1.11), a radial one, $v_r = dr/dt$, and an azimuthal one, v_φ. The angular momentum is expressed in terms of the azimuthal speed: $L = mrv_\varphi$. Hence, the mechanical energy of the particle can be written as

$$E = \frac{m(v_r^2 + v_\varphi^2)}{2} + E_{\rm p}(r) = \frac{m}{2}\left(\frac{dr}{dt}\right)^2 + \left[\frac{L^2}{2mr^2} + E_{\rm p}(r)\right].$$

It is apparent that the dependence $r(t)$ is the same as in a one-dimensional motion with the effective potential energy

$$E_{\rm p}^{\rm eff} = E_{\rm p} + \frac{L^2}{2mr^2}.$$

The second term is sometimes called the *centrifugal energy*. The graph of the effective potential curve is determined by the value of L, which can be evaluated from the initial conditions.

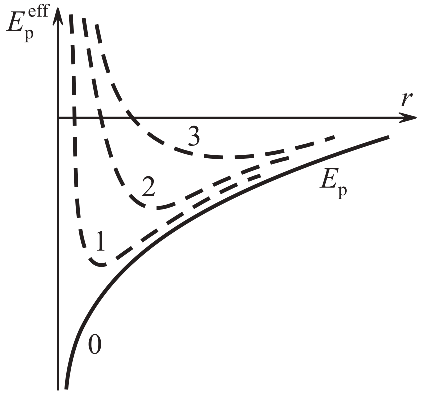

Figure P1.12. The form of the effective potential curve is determined by the angular momentum magnitude L.

Figure P1.12 depicts qualitatively the dependence of the effective potential energy $E_{\rm p}^{\rm eff}$ on the distance r for various L ($L_0 = 0$ and $L_1 < L_2 < L_3$) in the case that $E_{\rm p} = -b/r$. It is apparent that, for any L, the condition of finiteness of the motion remains the same: $E < 0$.

P1.6.3. Conservation of Angular Momentum for a System of Particles

► **Angular momentum of a system of particles.** The angular momentum of a system of particles about a point O is the vector sum of the angular momenta of the constituting particles. It is equal to

$$\mathbf{L} = \mathbf{r}_{\rm cm} \times \mathbf{p} + \mathbf{L}_{\rm rel}, \qquad \text{(P1.6.3.1)}$$

where $\mathbf{L}_{\rm rel}$ is the angular momentum in a center-of-mass frame. One of the consequences of equation (P1.6.3.1) is that if the linear momentum of the system is zero, the angular momentum $\mathbf{L}$ does not depend on the choice of the point O. Summing up equation (P1.6.2.2) over all point of the system and taking into account that the net moment of internal forces is zero, we find that

$$\frac{d\mathbf{L}}{dt} = \mathbf{M}^{\rm e}, \qquad \text{(P1.6.3.2)}$$

or *the time derivative of the angular momentum of the system equals the net moment of external forces.*

► **Law of conservation of angular momentum.** It follows from equation (P1.6.3.2) that *the angular momentum of a closed system is conserved.* The law of conservation of angular momentum is a fundamental law based on the postulate of isotropy of space (there is no selected direction in space). Just as with the laws of conservation of linear momentum and energy, the application of the law of conservation of angular momentum goes beyond the scope of Newtonian mechanics, where it was derived.

The angular momentum of a *unclosed* system is conserved in the following cases:

1. If the net moment of external forces $\mathbf{M}^{\mathrm{e}}$ is zero. (Example: a system of interacting particles in an external central field.)

2. If the moment of external forces about an axis is zero, then the angular momentum about this axis is conserved.

Example. If a weight of mass m attached to one end of a weightless string moves in a horizontal circle, the other end of the string fixed, then the angular momentum about any point at the axis of rotation (except for the center of the circle) is not conserved. However, the angular momentum about the axis of rotation is conserved, since the moment of the force of gravity and that of the tension force about this axis are both zero.

3. If the external forces are bounded, then the change in angular momentum $\Delta\mathbf{L}=\mathbf{M}^{\mathrm{e}}\Delta t$ in the short time of impact Δt can be neglected.

P1.6.4. Two-Body Problem. Reduced Mass

► **Reduced mass.** Consider a closed system consisting of two interacting particles. Solving the problem of motion of these particles (known as the *two-body problem*) means determining the particle positions at any time for given initial conditions. The positions of the particles are expressed in terms of the position of their center of mass $\mathbf{r}_{\mathrm{cm}}(t)$ (see (P1.4.1.1)) and their relative displacement $\mathbf{r}_{12} = \mathbf{r}_1 - \mathbf{r}_2$ as follows:

$$\mathbf{r}_1 = \mathbf{r}_{\mathrm{cm}} + \frac{m_2}{m_1 + m_2}\mathbf{r}_{12}, \qquad \mathbf{r}_2 = \mathbf{r}_{\mathrm{cm}} - \frac{m_1}{m_1 + m_2}\mathbf{r}_{12}.$$

The center of mass moves with a constant velocity, with the initial position and velocity found from the initial conditions (see equations (P1.4.1.1) and (P1.4.1.2)). Thus, solving the two-body problem is reduced to determining $\mathbf{r}_{12}$.

From the conditions of uniformity and isotropy of space and uniformity of time, it follows that the particles interact with central forces such that $\mathbf{F}_{12} = -\mathbf{F}_{21} = \mathbf{F}$, where $\mathbf{F}$ is parallel to $\mathbf{r}_{12}$ and the magnitude F is dependent on $|\mathbf{r}_{12}|$ only. Let us write the equations of motion for each particle:

$$\mathbf{F} = m_1\frac{d^2\mathbf{r}_1}{dt^2}, \qquad -\mathbf{F} = m_2\frac{d^2\mathbf{r}_2}{dt^2}.$$

Subtracting the second equation divided by m_2 from the first equation divided by m_1, we get

$$\left(\frac{1}{m_1} + \frac{1}{m_2}\right)\mathbf{F} = \frac{d^2\mathbf{r}_{12}}{dt^2} \qquad \text{or} \qquad \mathbf{F} = \mu\frac{d^2\mathbf{r}_{12}}{dt^2},$$

where μ is the reduced mass determined by

$$\frac{1}{\mu} = \frac{1}{m_1} + \frac{1}{m_2}, \qquad \text{so} \qquad \mu = \frac{m_1 m_2}{m_1 + m_2}. \tag{P1.6.4.1}$$

It is apparent that the vector $\mathbf{r}_{12}$ is determined by solving the problem of motion of a particle of mass μ in a central field.

► **Linear momenta and kinetic energies of two bodies in a center-of-mass frame.** The particle momenta in a center-of-mass frame, $\widetilde{\mathbf{p}}_1$ and $\widetilde{\mathbf{p}}_2$, are equal in magnitude (the total momentum is zero, with $\widetilde{\mathbf{p}}_2 = -\widetilde{\mathbf{p}}_1$ and $|\widetilde{\mathbf{p}}_1| = |\widetilde{\mathbf{p}}_2| = \widetilde{p}$) and are expressed in terms of the particle relative velocity (independent of the reference frame) as

$$|\mathbf{v}_{\text{rel}}| = \left|\left(\frac{\widetilde{\mathbf{p}}_1}{m_1} - \frac{\widetilde{\mathbf{p}}_2}{m_2}\right)\right| = \frac{\widetilde{p}}{\mu},$$

The kinetic energy of the system in the center-of-mass frame can also be expressed in terms of the relative velocity as

$$\widetilde{E}_{\text{k}} = \frac{\widetilde{p}^2}{2m_1} + \frac{\widetilde{p}^2}{2m_2} = \frac{\widetilde{p}^2}{2\mu} = \frac{\mu v_{\text{rel}}^2}{2}.$$

This formula was already encountered in considering inelastic collision (example 2, Subsection P1.5.3).

P1.7. Gravitational Field

P1.7.1. Law of Universal Gravitation. Superposition Principle

► **Newton's law of universal gravitation.** Two particles of masses m_1 and m_2 separated by a distance r are pulled to each other with a force of gravity (gravitational force) equal to

$$F = G\frac{m_1 m_2}{r^2}, \qquad \text{(P1.7.1.1)}$$

where $G \approx 6.673 \times 10^{-11}\,\text{N}\,\text{m}^2/\text{kg}^2$ is the gravitational constant. The gravitational force is a central force; it acts along the line connecting the particles.

The force exerted on a point mass m in a central field of gravity (gravitational field) produced by a fixed mass M can be represented as (see Subsection P1.3.3)

$$\mathbf{F} = -G\frac{mM}{r^2}\frac{\mathbf{r}}{r} \qquad \text{or} \qquad F_r(r) = -G\frac{mM}{r^2}. \qquad \text{(P1.7.1.2)}$$

Thus, the role of the "charge" for a gravitational field is played by the inertial mass m. This property is sometimes formulated as the *equivalence of gravitational and inertial masses*. The potential energy of a particle in a central field of gravity can be found by using the relation between force and potential energy (formula (P1.5.2.4)); we have $-GmM/r^2 = -dE_{\text{p}}/dr$, so $E_{\text{p}} = -GmM/r + \text{const}$. The constant is usually set to zero, thus taking the potential energy to be zero at infinity:

$$E_{\text{p}} = -G\frac{mM}{r}. \qquad \text{(P1.7.1.3)}$$

► **Principle of superposition.** If a field of gravity is generated by several point masses, $M_1, \ldots, M_N$, then the force acting on a particle m and its potential energy are expressed as

$$\begin{aligned} \mathbf{F} &= \sum \mathbf{F}_j = -\sum G\frac{mM_j}{(\mathbf{r}-\mathbf{r}_j)^2}\frac{\mathbf{r}-\mathbf{r}_j}{|\mathbf{r}-\mathbf{r}_j|}, \\ E_{\text{p}} &= \sum E_{\text{p}j} = -\sum G\frac{mM_j}{|\mathbf{r}-\mathbf{r}_j|}, \end{aligned} \qquad \text{(P1.7.1.4)}$$

where $\mathbf{r}$ is the position vector of the particle m and $\mathbf{r}_j$ is the position vector of the mass point M_j. If a gravitational field is generated by a continuously distributed mass, then the summation in (P1.7.1.4) must be replaced by integration.

P1.7.2. Strength and Potential of Gravitational Field

► **Strength and potential of the gravitational field generated by a point mass.** It is apparent from equations (P1.7.1.4) that both the force acting on a particle of mass m in a gravitational field and the potential energy of the particle are proportional to m. Hence, the specific force, $\mathbf{F}/m$, and specific energy, $E_{\rm p}/m$, are independent of m and so characterize the field itself. These are called the *strength* and *potential* of the gravitational field, respectively, and denoted

$$\mathbf{g}=\frac{\mathbf{F}}{m},\qquad \varphi=\frac{E_{\rm p}}{m}.$$

The field strength has a simple physical meaning: it is the *acceleration due to gravity*, or the acceleration acquired by any particle placed at a given point due to the action of the gravitational field only. The strength and potential created by a point mass M are expressed as

$$\mathbf{g}=-G\frac{M}{r^2}\frac{\mathbf{r}}{r},\qquad \varphi=-G\frac{M}{r}.\tag{P1.7.2.1}$$

The strength and potential of the gravitation field generated by several point masses are calculated using the principle of superposition. For example, let us write equations (P1.7.2.1) for the case of a body with distributed mass:

$$\mathbf{g}(\mathbf{r})=-\int G\frac{\rho(\mathbf{r}')}{(\mathbf{r}-\mathbf{r}')^2}\,\frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|}\,dV',\qquad \varphi(\mathbf{r})=-\int G\frac{\rho(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}\,dV',\tag{P1.7.2.2}$$

where $\rho(\mathbf{r})$ is the mass density at the position $\mathbf{r}$ and the integration is performed over the volume occupied by the body.

Example 1. Show that the gravitational strength inside a hollow spherical layer is zero.

Solution. For a given point A, consider the contributions to the field strength of the small regions B and C cut out from the sphere by a thin cone with apex at A (Fig. P1.13). The ratio of the areas of these regions, and hence the ratio of their masses, equals the ratio of the squared distances of the regions to the point A. It follows that the strengths produced by the regions B and C at A are equal in magnitude.

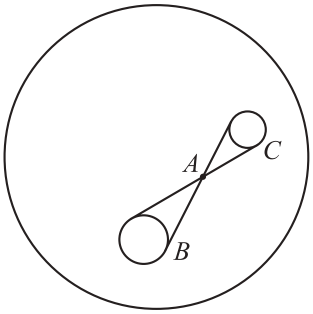

Figure P1.13. The strengths of the gravitational fields generated by opposite regions on a spherical surface cancel each other out.

The field strength produced by a thin hollow sphere of mass M outside the sphere turns out to be equal to the strength produced by a point mass M placed at the sphere center. Cumbersome integration is required to prove this result (Newton was first to do this). In Chapter P3, this statement will be proved using Gauss's theorem. The same result holds true for any spherically symmetric distributed mass and, in particular, for any spherical planet.

Example 2. Suppose a mass M is uniformly distributed along a segment of length l. Compute the gravitational strength and potential at the point lying outside on the continuation of the segment at a distance x from its center.

Solution. The mass of a segment of length dy equals $dm = M\,dy/l$. Integrating yields

$$g(x) = -G\int_{x-l/2}^{x+l/2} \frac{M\,dy}{ly^2} = -G\frac{M}{x^2 - (l/2)^2},$$

$$\varphi(x) = -G\int_{x-l/2}^{x+l/2} \frac{M\,dy}{ly} = -G\frac{M}{l}\ln\frac{x + l/2}{x - l/2}.$$

It is apparent that a symmetric but nonspherical body cannot be replaced by a point mass placed at its center. This example illustrates also that the strength and potential are linked by the relation $g_x = -\partial\varphi/\partial x$, which is similar to (P1.5.2.2).

P1.7.3. Motion in a Central Field of Gravity. Kepler's Laws. Orbital and Escape Velocities

► **Motion in a central field of gravity. Kepler's laws.** Motion in a central field of gravity obeys the general laws of motion in a central field. However, it has some specific features reflected in Kepler's first and third laws initially formulated for planets of the solar system.

Kepler's first law states that a finite motion ($E < 0$) of a particle in a central gravitational field occurs in a closed path—an ellipse with the force center (the sun) located at one of its foci.

Kepler's second law affirms the constancy of the areal velocity, i.e., the rate at which the radius vector of the moving particle sweeps area. This law holds for any central field and follows directly from the law of conservation of momentum (see Subsection P1.6.2).

Kepler's third law states that, for any two particles moving in a central gravitational field, the ratio of the squares of their orbital periods equals the ratio of the cubes of the semimajor axes of their orbits: $T_1^2/T_2^2 = a_1^3/a_2^3$.

Kepler's first law should be supplemented with the statement that an infinite motion of a particle in a central gravitational field occurs in either a parabola ($E = 0$) or a hyperbola ($E > 0$). The third law can be supplemented by the relationship between the specific energy of orbital motion and the semimajor axis: $|E|/m = GM/(2a)$. It is apparent that the orbital period is uniquely determined by the specific energy of the moving particle.

► **Orbital and escape velocities.** The *orbital velocity* (also known as the *first cosmic velocity*) of a small body around a planet is the speed at which the body moves in a circular orbit around the planet near its surface, with the atmospheric drag neglected. The orbital speed is determined from the equation $mg = mv_{\rm o}^2/R$ and equals $v_{\rm o} = \sqrt{gR} = \sqrt{GM/R}$, where M is the mass of the planet. (For Earth, $v_{\rm o} \approx 7.9\,\text{km/s}$.)

The *escape velocity* (also known as the *second cosmic velocity*) of a body is the minimum speed the body must have to "break free" from a planet's gravitational pull and go to infinity. As follows from Subsection P1.6.2, the condition for a motion to be infinite is the inequality $E \ge 0$; hence, the escape velocity is determined by the equation $mv_{\rm e}^2/2 - GmM/R = 0$ and equals $v_{\rm e} = \sqrt{2GM/R} = \sqrt{2gR}$. (For Earth, $v_{\rm e} \approx 11.2\,\text{km/s}$.)

P1.8. Non-Inertial Reference Frames

P1.8.1. Definition of Fictitious Forces

In many cases, it is convenient to solve a dynamics problem in a non-inertial frame of reference (a reference frame that is not inertial) instead of recalculating results first obtained in an inertial frame. To this end, *fictitious forces* (also called *inertial forces*) are introduced as follows. In Newton's second law for a particle of mass m moving under the action of a net force $\mathbf{F}$, the acceleration is first represented as the sum of two components, $\mathbf{a} = \mathbf{a}_{\rm rel} + \mathbf{a}^*$, where $\mathbf{a}_{\rm rel}$ is the acceleration of the particle in the non-inertial frame. Then the other component, multiplied by m, is transferred to the other side of the equation and called the fictitious force. So we have

$$\begin{aligned} \mathbf{F} &= m\mathbf{a}, \\ \mathbf{F} &= m(\mathbf{a}_{\rm rel} + \mathbf{a}^*), \\ \mathbf{F} + (-m\mathbf{a}^*) &= m\mathbf{a}_{\rm rel}, \\ \mathbf{F} + \mathbf{F}_{\rm fict} &= m\mathbf{a}_{\rm rel}. \end{aligned}$$

The fictitious forces are thus defined by

$$\mathbf{F}_{\rm fict} = -m\mathbf{a}^*, \qquad \text{(P1.8.1.1)}$$

where the acceleration $\mathbf{a}^*$ is determined by the kinematic equation

$$\mathbf{a} = \mathbf{a}_{\rm rel} + \mathbf{a}^* \qquad \text{(P1.8.1.2)}$$

and is dependent on the non-inertial frame itself and the position and velocity of the particle in it. Consider some specific cases.

P1.8.2. Translationally Moving Non-Inertial Frames

In this case, $\mathbf{a}^*$ equals the acceleration of the inertial frame K (see formula (P1.1.4.1)). Then the fictitious force is expressed as

$$\mathbf{F}_{\rm fict} = -m\mathbf{a}_K.$$

It is apparent that the fictitious force here is equivalent to the force of gravity. So it is convenient to combine the two forces together in solving problems. With this done, the introduction of a fictitious force turns out to be equivalent to adjusting the acceleration due to gravity (see Subsection P1.7.2), so that $\mathbf{g}$ is effectively replaced by $\mathbf{g}^* = \mathbf{g} + \mathbf{a}^* = \mathbf{g} - \mathbf{a}_K$.

Example. A container filled with a liquid moves with a constant horizontal acceleration $\mathbf{a}$. Find the angle β between surface of the liquid and the horizontal plane.

Solution. In a reference frame associated with the container, the liquid surface is at rest and "horizontal," which means that it is perpendicular to the vector $\mathbf{g}^* = \mathbf{g} + \mathbf{a}^* = \mathbf{g} - \mathbf{a}$. So we need to find the angle between $\mathbf{g}$ and $\mathbf{g} - \mathbf{a}$. We have $\tan\beta = a/g$.

The principle of equivalence of inertial and gravitational forces was laid by Einstein at the basis of his *general theory of relativity*, which is a relativistic theory of gravitation and explains the appearance of gravitational forces by the fact that the space–time continuum is curved by external massive bodies.

P1.8.3. Uniformly Rotating Reference Frame

In this case the kinematic equation for the acceleration (P1.8.1.2) becomes: $\mathbf{a} = \mathbf{a}_{\rm rel} + \boldsymbol{\omega} \times (\boldsymbol{\omega} \times \mathbf{r}) + 2\boldsymbol{\omega} \times \mathbf{v}_{\rm rel}$ (see Subsection P1.2.2). The second term is associated with the rotation of the translatory velocity $\boldsymbol{\omega} \times \mathbf{r}$ together with the reference frame. This vector is directed toward the axis of rotation and its magnitude equals $\omega^2 R$ (R is the distance to the axis), and hence it is the normal (centripetal) acceleration of the reference frame at the given point.

The third term (Coriolis acceleration) is due to, first, the rotation of $\mathbf{v}_{\text{rel}}$ together with the reference frame and, second, the change in the translatory velocity $\boldsymbol{\omega}\times\mathbf{r}$ due to the movement of the particle from one point of the rotating non-inertial frame to another. Accordingly, the fictitious force (P1.8.1.1) is the sum of two components, the first called the *centrifugal force* and the second called the *Coriolis force*:

$$\mathbf{F}_{\text{fict}} = \mathbf{F}_{\text{cf}} + \mathbf{F}_{\text{Cor}} = m\omega^2\mathbf{R} + 2m\mathbf{v}_{\text{rel}}\times\boldsymbol{\omega}. \tag{P1.8.3.1}$$

The centrifugal fictitious force is directed outward from the axis of rotation ($\mathbf{R}$ is directed from the axis and is perpendicular to it). Since it is independent of the particle velocity, its action is indistinguishable from a (nonuniform) gravitational field. For example, the force of gravity measured at the Earth's surface is the sum of the gravitational force and the centrifugal inertial force.

The Coriolis force is perpendicular to the particle velocity. For example, in the Northern hemisphere, for motions along the Earth's surface the horizontal component of the Coriolis force is directed to the right of the motion, which exhibits itself in the formation of cyclones (rotate counterclockwise), greater erosion of right river banks, etc.

Example. Find the deflecting action of the Coriolis force onto a body freely falling on the Earth's surface from a height h at the equator.

Solution. Since the deviation is small, the "undisturbed" velocity of free falling $\mathbf{v} = \mathbf{g}t$ can be substituted in the Coriolis force (P1.8.3.1). The vector $\boldsymbol{\omega}$ is perpendicular to $\mathbf{v}$, and hence the Coriolis force is directed eastward, its magnitude equal $2mv\omega$, and the horizontal acceleration imparted to the body is $a_{\text{east}} = 2\omega gt$. Integrating yields the horizontal speed $v_{\text{east}} = g\omega t^2$ and the horizontal displacement $s_{\text{east}} = \frac{1}{3}g\omega t^3$. Substituting the time of falling $t = \sqrt{2h/g}$ gives the final deviation. For example, if the initial height is $h = 300$ m, the final deviation is approximately 10 cm.

P1.9. Dynamics of Rigid Body

P1.9.1. Rotation About a Fixed Axis

For a rigid body consisting of many particles of mass m_j and rotating about a fixed axis z with an angular velocity ω, the magnitude of its angular momentum about the axis (see Subsection P1.6.2) equals

$$|L_z| = \sum_j R_j m_j v_j = \omega\sum_j m_j R_j^2 = I_z\omega, \tag{P1.9.1.1}$$

where R_j is the distance from the particle m_j to the axis; the relation $v_j = \omega R_j$ has been used here. The angular momentum direction coincides with that of $\boldsymbol{\omega}$ (determined by the right hand rule). The quantity

$$I_z = \sum_j m_j R_j^2 = \int R^2\,dm \tag{P1.9.1.2}$$

is called the *moment of inertia* of the body about the axis z. Differentiating (P1.9.1.1) with respect to time and taking into account that $dL_z/dt = M_z$, where M_z is the moment of external forces about the axis of rotation (see equation (P1.6.3.2)), we get

$$M_z = I_z\varepsilon, \tag{P1.9.1.3}$$

where $\varepsilon = d\omega/dt$ is the angular acceleration. This equation is referred to as the *basic equation of rotational dynamics of a rigid body about a fixed axis*. Compute also the kinetic energy of the rotating body,

$$E_\text{k} = \sum_j \frac{m_j v_j^2}{2} = \tfrac{1}{2}\omega^2 \sum_j m_j R_j^2 = \tfrac{1}{2} I_z \omega^2, \tag{P1.9.1.4}$$

and the work done by an external force **F** on rotating the body,

$$A = \int d\mathbf{r} \cdot \mathbf{F} = \int (\boldsymbol{\omega}\, dt \times \mathbf{r}) \cdot \mathbf{F} = \int (\boldsymbol{\omega}\, dt) \cdot (\mathbf{r} \times \mathbf{F}) = \int \mathbf{M} \cdot d\boldsymbol{\varphi},$$

where $d\boldsymbol{\varphi} = \boldsymbol{\omega}\, dt$.

Example. A body of mass m is attached to one end of a weightless rope wound around a pulley of radius R and moment of inertia I. Find the acceleration of the body after it has been released.

Solution. Let us write Newton's second law for the body: $mg - T = ma$. The equation of motion of the pulley (P1.9.1.3) is $TR = I\varepsilon$. Using the kinematic relation $a = \varepsilon R$ (the rope does not slide against the pulley) and solving the above equations for a, we obtain $a = g/(1 + I/mR^2)$.

P1.9.2. Properties of Moment of Inertia

The moment of inertia (P1.9.1.2) is a scalar quantity that characterizes the distribution mass of the body relative to the axis of rotation. It can be seen from equations (P1.9.1.3) and (P1.9.1.4) that the moment of inertia is a measure of the body's inertia with respect to rotational motion; moment of inertia plays the same role as mass in translational motion.

Example. Compute the moment of inertia of a thin disk of mass m and radius R about its axis of symmetry.

Solution. Dividing the disk into thin circular rings and integrating, we obtain

$$I = \int r^2\, dm = \int_0^R r^2 \Bigl(\frac{m}{\pi R^2}\Bigr) 2\pi r\, dr = \frac{mR^2}{2}.$$

The same result holds also for a homogeneous solid cylinder.

► **Parallel axis theorem.** The *parallel axis theorem* (also known as the *Huygens–Steiner theorem*) relates the moment of inertia I about an arbitrary axis to the moment of inertia I_0 about a parallel axis passing through the center of mass of the body:

$$I = I_0 + ma^2, \tag{P1.9.2.1}$$

where m is mass of the body and a is the distance between the axes. For example, the moment of inertia of a disk about an axis perpendicular to its plane and passing through its edge equals $\frac{1}{2}mR^2 + mR^2 = \frac{3}{2}mR^2$. The minimum moment of inertia among all parallel axes is for the axis passing the center of mass.

► **Perpendicular axis theorem.** The *perpendicular axis theorem* asserts that the moment of inertia of a plane body about an arbitrary axis z perpendicular to the body plane equals the sum of the moments of inertia about mutually perpendicular axes x and y lying in the body plane and intersecting z:

$$I_z = I_x + I_y.$$

For example, the moment of inertia of a thin disk about an axis of symmetry lying in its plane equals $I_x = I_y = \frac{1}{2}I_z = \frac{1}{4}mR^2$.

► **Moments of inertia of some bodies.** Listed below are moments of inertia of some bodies of various shape.

1) Thin ring of radius R (about its axis of symmetry): $I = mR^2$. The same result holds for a thin hollow cylinder (without end caps).

2) Thin rod of length l (about an axis through its center and perpendicular to its axis): $I = \frac{1}{12}ml^2$. A thin rectangular plate has the same moment of inertia about the axis through the centers of its opposite sides having the length l. The moment of inertia about a parallel axis through one of the ends of the rod equals $I = \frac{1}{3}ml^2$.

3) A thin rectangular plate (about the axis through its center and perpendicular to its plane): $I = \frac{1}{12}m(a^2 + b^2)$. A rectangular parallelepiped has the same moment of inertia about the axis through the centers of its opposite faces.

4) Thin spherical shell (about its axis of symmetry): $I = \frac{2}{3}mR^2$.

5) Homogeneous solid ball (about its axis of symmetry): $I = \frac{2}{5}mR^2$.

6) Hollow cylinder with inner radius R_1 and outer radius R_2: $I = \frac{1}{2}m(R_1^2 + R_2^2)$.

P1.9.3. Plane Motion of a Rigid Body

Plane motion of a rigid body is the superposition of translational motion of its center of mass and rotational motion in a center-of-mass frame (see Subsection P1.4.2). The motion of the center of mass is described by Newton's second law and determined by the net external force (equation (P1.4.2.1)), where only real external forces must be taken into account, since the moment of fictitious forces relative to the center of mass is zero (just like in the case of the forces of gravity in the example of Subsection P1.6.1). The kinetic energy of plane motion equals $E_k = \frac{1}{2}mv_{cm}^2 + \frac{1}{2}I_0\omega^2$ (see equation (P1.5.1.3)). The angular momentum about a fixed axis perpendicular to the plane of motion is calculated as (see equation (P1.6.1.3)): $L_z = \pm mv_{cm}d \pm I_0\omega$, where d is the arm of the center-of-mass velocity relative to the axis, and the plus or minus sign is determined by the positive direction of rotation selected.

Example 1. Find the acceleration of a round body that rolls down an inclined plane without slipping (Fig. P1.14). The radius of the body is R, its mass is m, and the moment of inertia about the central axis is I. The angle between the inclined plane and the horizontal surface is α.

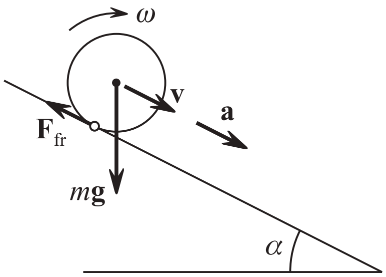

Figure P1.14. Forces acting on a body rolling down an inclined plane.

Solution. The equations of motion are: $mg\sin\alpha - F_{fr} = ma$ and $F_{fr}R = I\varepsilon$. The no-slipping condition ($v = \omega R$) leads to the equation $a = \varepsilon R$ (see the example in Subsection P1.2.1). Solving the above equations gives the acceleration $a = g\sin\alpha/(1 + I/mR^2)$. Since the static friction force does not produce any work, the mechanical energy is conserved.

Example 2. A thin rod of length l and mass M rests on a smooth horizontal plane. A ball of mass m moves in the plane and undergoes an elastic collision with an end of the rod perpendicularly to the line of the rod. The final speed of the ball, u, and the rod center, V, as well as angular velocity of the rod, ω, after the collision are determined from the following three equations:

1) law of conservation of linear momentum: $mv = mu + MV$,

2) law of conservation of energy: $mv^2/2 = mu^2/2 + MV^2/2 + (Ml^2/12)\omega^2/2$,
3) law of conservation of angular momentum (e.g., about the point of impact): $0 = MV(l/2) - (Ml^2/12)\omega$.

P1.9.4. Motion with a Fixed Point

For a rigid body rotating about a fixed point, its angular velocity is directed along the instantaneous axis of rotation and changes its direction both in space and relative to the body itself. The equation of motion

$$\frac{d\mathbf{L}}{dt} = \mathbf{M}^{\mathrm{e}},$$

which is referred to as the *basic equation of motion of a rigid body with a fixed point*, allows us to find out how the angular momentum $\mathbf{L}$ changes in time. Since $\mathbf{L}$ is generally non-parallel to the angular velocity $\boldsymbol{\omega}$, we need an equation that relates $\mathbf{L}$ and $\boldsymbol{\omega}$ in order to close the system of equations of motion.

Example. As an inclined dumbbell rotates about a vertical axis (as shown in Fig. P1.15), its angular momentum $\mathbf{L} = \mathbf{r}_1 \times \mathbf{p}_1 + \mathbf{r}_2 \times \mathbf{p}_2$ is perpendicular to the straight line connecting the masses m_1 and m_2 of the dumbbell and directed at a non-right angle to the axis of rotation. Also the vector $\mathbf{L}$ itself rotates about the vertical axis with the angular velocity $\boldsymbol{\omega}$.

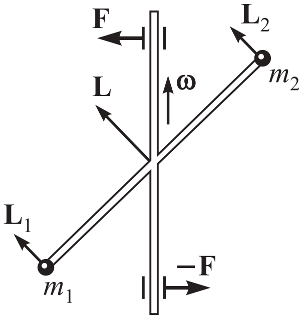

Figure P1.15. The vector of angular momentum $\mathbf{L}$ can be nonparallel to the axis of rotation (to $\boldsymbol{\omega}$).

► **Theorem of principal axes of inertia.** The relationship between $\mathbf{L}$ and $\boldsymbol{\omega}$ can be found using the *theorem of principal axes of inertia* which states that for any rigid body and any point O there are three mutually perpendicular axes through O such that, when the body rotates about any of these axes, the vector $\mathbf{L}$ is parallel to the axis: $\mathbf{L}_i = I_i \boldsymbol{\omega}_i$ $(i = 1, 2, 3)$. The moments of inertia about these axes are called *principal moments of inertia*. If the rotation occurs about an arbitrary axis through O, the angular velocity can be resolved into its projections onto the principal axes, $\boldsymbol{\omega} = \boldsymbol{\omega}_1 + \boldsymbol{\omega}_2 + \boldsymbol{\omega}_3$, and the angular momentum can be expressed as

$$\mathbf{L} = I_1 \boldsymbol{\omega}_1 + I_2 \boldsymbol{\omega}_2 + I_3 \boldsymbol{\omega}_3. \qquad \text{(P1.9.4.1)}$$

(Likewise, $\mathbf{L}$ can be resolved into its projections onto the principal axes and then $\boldsymbol{\omega}$ can be expressed in terms of them.)

If the principal axes are through the center of mass (center of inertia) of the body, they are called *free axes*. When the body rotates about any of the free axes (free rotation), both the linear momentum and the angular momentum of the body are conserved, which means that there is no need to apply an external force or external moment to maintain rotation. (In the above example, the net force is zero; however, there are a couple of forces arising at points of support whose moments provide change of $\mathbf{L}$ with time.) It should be noted that free rotation is stable only about two of the three axes, the ones with the minimum and maximum principal moments of inertia.

Example 1. When is the choice of the free axes unique?

Solution. The free axes are uniquely determined only if the three principal moments of inertia are all different. If two moments are equal (e.g., $I_1 = I_2 = I$), then any axis that lies in the plane of the two free axes is also a free axis, with $\mathbf{L} = I\boldsymbol{\omega}_1 + I\boldsymbol{\omega}_2 = I\boldsymbol{\omega}$. If all three principal moments of inertia are equal (e.g., such is a homogeneous cube), then any axis through the center of mass is a free axis.

Example 2. Given three principal moments of inertia (I_1, I_2, and I_3) of a body, find the moment of inertia I about the axis that makes angles γ_1, γ_2, and γ_3 with the principal axes.

Solution. The kinetic energy of the body rotating with an angular velocity ω about the specified axis can be calculated in two ways. On the one hand, it is equal to

$$E = \frac{I\omega^2}{2}.$$

On the other hand,

$$E = \frac{L_\omega \omega}{2} = \frac{(\mathbf{L}\cdot\boldsymbol{\omega})}{2} = \frac{I_1\omega_1^2}{2} + \frac{I_2\omega_2^2}{2} + \frac{I_2\omega_2^2}{2},$$

where $L_\omega = I\omega$ is the projection of $\mathbf{L}$ onto $\boldsymbol{\omega}$. Since $\omega_i/\omega = \cos\gamma_i$, we find that

$$I = I_1\cos^2\gamma_1 + I_2\cos^2\gamma_2 + I_3\cos^2\gamma_3.$$

Example 3. Free symmetric top. Nutation of the Earth's axis. Let is find out how the position of the axis of rotation changes relative to a rotating body (in a reference frame associated with the body). Let us confine ourselves to the case of a *free symmetric top*, or a freely rotating body with $I_1 = I_2 = I_\perp$ and $I_3 = I_\| \neq I_\perp$. (The Earth is an example of such a top.) For a symmetric top, the vector $\mathbf{L} = I_\|\boldsymbol{\omega}_\| + I_\perp\boldsymbol{\omega}_\perp$ lies in the same plane as the third axis (axis of symmetry) and the vector $\boldsymbol{\omega} = \boldsymbol{\omega}_\| + \boldsymbol{\omega}_\perp$. In an inertial reference frame, the angular momentum $\mathbf{L}$ is conserved. Consequently, in the rotating top-related reference frame, the vector $\mathbf{L}$ performs rotation with an angular velocity $\boldsymbol{\omega}$ at the current time, and hence it obeys the equation

$$\frac{d\mathbf{L}}{dt} = \boldsymbol{\omega}\times\mathbf{L}.$$

This equation is called *Euler's equation* (usually, a system of three scalar equations is written out which is obtained by projecting this vector equation onto axes 1, 2, and 3 taking into account relation (P1.9.4.1)). The complexity of Euler's equation is that the vector $\boldsymbol{\omega}$ is not constant but linked to $\mathbf{L}$ by the linear relation (P1.9.4.1). For a symmetric top, $\boldsymbol{\omega}\times\mathbf{L}$ is perpendicular to the plane ($\boldsymbol{\omega}$, $\mathbf{L}$); hence, $d\mathbf{L}_\|/dt = I_\| d\boldsymbol{\omega}_\|/dt = \mathbf{0}$ ($\omega_\| = \text{const}$). For $\boldsymbol{\omega}_\perp$, we have the equation

$$I_\perp\frac{d\boldsymbol{\omega}_\perp}{dt} = (\boldsymbol{\omega}_\| + \boldsymbol{\omega}_\perp)\times(I_\|\boldsymbol{\omega}_\| + I_\perp\boldsymbol{\omega}_\perp) = (I_\perp - I_\|)\,\boldsymbol{\omega}_\|\times\boldsymbol{\omega}_\perp$$

or

$$\frac{d\boldsymbol{\omega}}{dt} = \boldsymbol{\Omega}\times\boldsymbol{\omega}, \qquad \text{where} \quad \boldsymbol{\Omega} = \frac{(I_\perp - I_\|)}{I_\perp}\boldsymbol{\omega}_\|$$

This equation shows that in the top-related frame, the axis of rotation performs a circular motion about axis 3 with the angular velocity $\boldsymbol{\Omega}$. For the Earth, there is a small relative difference between the moments of inertia $I_\perp$ and $I_\|$, which leads to a slow periodic motion of the Earth's axis (*nutation of the Earth's axis*) with a period of tens of days.

► **Gyroscopes.** A gyroscope is a rigid body that rapidly spins about its axis of symmetry. The problem of motion of the gyroscope's axis can be solved in the so-called *gyroscope approximation*, $\mathbf{L} = I\boldsymbol{\omega}$, where both $\mathbf{L}$ and $\boldsymbol{\omega}$ are directed along the axis of symmetry. A perfectly balanced gyroscope is a gyroscope whose center of mass is fixed. It possesses the property of being *inertialess*: its axis stops moving as soon as the external action is removed ($\mathbf{M} = \mathbf{0}$). This property allows to use such gyroscopes to preserve orientation in space. A *heavy gyroscope* is a gyroscope whose center of mass is displaced by a distance d from the fixed point (Fig. P1.16). The moment of the force of gravity acting on a heavy gyroscope is perpendicular to $\mathbf{L}$. Since $d\mathbf{L}/dt \perp \mathbf{L}$, the angular momentum $\mathbf{L}$ and the gyroscope's axis perform regular rotation about the vertical axis (*precession of a gyroscope*). The end of the vector $\mathbf{L}$ moves in a horizontal circle of radius $L\sin\alpha$ with the angular velocity

$$\Omega = \frac{|d\mathbf{L}/dt|}{L\sin\alpha} = \frac{mgd\sin\alpha}{I\omega\sin\alpha} = \frac{mgd}{I\omega}.$$

The angular velocity of precession is independent of the angle α made by the axis of rotation with the vertical.

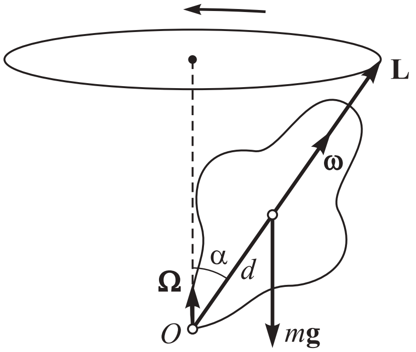

Figure P1.16. Gyroscope precession in the field of gravity.

P1.10. Special Theory of Relativity

P1.10.1. Basics of the Special Theory of Relativity

Einstein's *special theory of relativity* (STR), also known as *special relativity* (SR), extends the limits of classical Newtonian physics, valid for *nonrelativistic velocities* (small compared to the speed of light c), to any velocities, including *relativistic* (comparable with c). In the classical limit $v/c \to 0$, all results of special relativity reduce to results of classical, nonrelativistic physics.

► **Postulates of STR.** The special theory of relativity relies on two postulates:

The *principle of relativity*: all physical laws, both mechanical and electromagnetic, have the same form in all inertial reference frames. This implies that no inertial reference frame can be distinguished from any other by any experiments and taken to be the rest inertial frame. This postulate is an extension of the Galilean relativity principle (see Subsection P1.3.4) to electromagnetic phenomena.

The *principle of invariant light speed*: the speed of light in vacuum is the same for any inertial frame and equals $c \approx 3 \times 10^8$ m/s. This postulate contains two statements: (i) the speed of light is independent of the state of motion of the light source and (ii) the speed of light is independent of which inertial frame is the observer measuring this speed in (i.e., independent of the speed of the receiver).

The invariance of the light speed and its independence of the state of motion of the light source follow from Maxwell's equations of electromagnetic field. It seemed obvious that this statement could hold in only one reference frame. From the classical conceptions of space and time, any other observer moving with a speed v relative to this frame should measure the speed of light as $c+v$ if moving toward the source or $c-v$ if moving away from the source. This result would mean that Maxwell's equations hold in only one reference frame filled with quiescent "ether," through which electromagnetic waves travel. However, the attempt to detect a change in the light speed due to Earth's motion relative to the ether (Michelson–Morley experiment) failed to detect such a change. Einstein put forward the hypothesis that Maxwell's equations, as well as all physics laws, must have the same form in all inertial frames, and hence the light speed must be the same in all inertial frames. This hypothesis led to revision of the basic concepts of space and time.

► **Lorentz transformations.** The Lorentz transformations link the coordinates and time of an event measured in two inertial frames, one of which (K') moves relative to the other (K) with a constant velocity **V**. If the coordinate axes and the initial instant are chosen in the same way as in the Galilean transformations (see formulas (P1.3.4.1)), the Lorentz transformations have the form

$$x' = \frac{x - Vt}{\sqrt{1 - V^2/c^2}}, \quad y' = y, \quad z' = z, \quad t' = \frac{t - (V/c^2)x}{\sqrt{1 - V^2/c^2}}. \qquad \text{(P1.10.1.1)}$$

It is often convenient to use the transformations for the differences of the coordinates and time instants of two events:

$$\Delta x' = \gamma(\Delta x - V\Delta t), \quad \Delta y' = \Delta y, \quad \Delta z' = \Delta z, \quad \Delta t' = \gamma\left[\Delta t - (V/c^2)\Delta x\right]. \quad \text{(P1.10.1.2)}$$

where the notation

$$\gamma = \frac{1}{\sqrt{1 - V^2/c^2}}, \qquad \gamma \ge 1, \qquad \text{(P1.10.1.3)}$$

is used for brevity. The Lorentz transformations reduce to the Galilean transformations for $V \ll c$. The Lorentz transformations are derived from the second pustulate of STR (invariance of light speed) and the requirement of linearity of the transformations (this requirement expresses the condition of uniformity of space). The *inverse transformations*, expressing the coordinates and time in K via those in K', can be obtained from (P1.10.1.1) and (P1.10.1.2) by substituting $-V$ for V:

$$\Delta x = \gamma(\Delta x' + V\Delta t'), \quad \Delta y = \Delta y', \quad \Delta z = \Delta z', \quad \Delta t = \gamma\left[\Delta t' + (V/c^2)\Delta x'\right]. \quad \text{(P1.10.1.4)}$$

P1.10.2. Consequences of the Lorentz Transformations. STR Kinematics

► **Length contraction.** The length of a moving segment is defined as the distance between the points at which the segment ends were at the same time (i.e., $\Delta t = 0$). Consider a rigid body that moves translationally with a speed v and let K' denote a reference frame associated with it. From equation (P1.10.1.2), where one should set $V = v$ and $\Delta t = 0$, one finds that the longitudinal dimension of a moving body is reduced:

$$l = l_0/\gamma = l_0\sqrt{1 - v^2/c^2}, \qquad \text{(P1.10.2.1)}$$

where l_0 is the proper longitudinal dimension measured in frame K', where the body is at rest. The transverse dimensions of a moving body do not change.

Example 1. A square plate moving at the speed $v = 0.8\,c$ along one of its sides becomes a rectangular with the angle between the diagonals equal to arccot $\sqrt{1 - v^2/c^2} = \operatorname{arccot} 0.6 \approx 59^\circ$.

► **Time dilation.** It can be seen from the Lorentz transformations that time passes differently in different inertial frames. In particular, two events occurring simultaneously ($\Delta t = 0$) but at different points in frame K may not be simultaneous in frame K', so that $\Delta t' = -\gamma V\Delta x/c^2$ can be positive or negative. This effect is known as *relativity of simultaneity*. A clock that moves together with frame K' (i.e., that rests relative to K', with $\Delta x' = 0$) shows the *proper time* of this frame. For an observer in frame K, this clock is slow (*time dilation*). Considering two readings of the moving clock as two events, we find from (P1.10.1.4) that

$$\Delta t = \gamma\Delta\tau = \frac{\Delta\tau}{\sqrt{1 - V^2/c^2}}, \qquad \text{(P1.10.2.2)}$$

where $\Delta\tau = \Delta t'$ is the proper time of the moving clock (to be precise, of the associated reference frame). The fact that all reference frames are indistinguishable manifests itself in that a clock resting relative to frame K appears to the observer in frame K' to lag behind the observer's clock in K'. (Note that, to control the moving clock, the stationary observer in K uses *different* clocks at different instants.)

The *twin paradox* consists in that special relativity predicts a change in the age of two twins, one of which stayed on the Earth and the other traveled in deep space at relativistic speeds and then returned to the Earth (the traveler will be younger). It may seem as though this thought experiment violates the principle of indistinguishability of reference frames. In fact, the Earth's twin stayed all the time in one and the same inertial frame but the astronaut changed his or her frame to return to the Earth (the astronaut-associated frame was not inertial).

Example 2. The mean proper lifetime of the muon (an unstable subatomic particle) is $\tau = 2.2\times10^{-6}$ s, with $c\tau \sim 660$ m (c is the speed of light). Due to time dilation, from the viewpoint of an Earth's observer, a space muon flying with a relativistic speed v with $\gamma \gg 1$ has a mean lifetime of $\gamma\tau$ and travels a distance $c\gamma\tau$ from its birth in upper atmosphere, which allows detecting the muon on the Earth's surface.

► **Velocity addition in special relativity.** If a particle moves with velocity $\mathbf{v}'$ relative to frame K', then its velocity relative to frame K can be found by expressing dx, dy, dz, and dt from (P1.10.1.4) and substituting into $v_x = dx/dt$, $v_y = dy/dt$, and $v_z = dz/dt$ to obtain

$$v_x = \frac{v'_x + V}{1 + v'_x V/c^2}, \quad v_y = \frac{v'_y\sqrt{1 - V^2/c^2}}{1 + v'_x V/c^2}, \quad v_z = \frac{v'_z\sqrt{1 - V^2/c^2}}{1 + v'_x V/c^2}. \qquad \text{(P1.10.2.3)}$$

For nonrelativistic speeds, $v_x \ll c$ and $V \ll c$, the above formulas reduce to the nonrelativistic velocity-addition law (see equation (P1.1.4.1)). Formulas (P1.10.2.3) have the important property that if V and v' less than c, then v is also less than c. For example, if the particle is first accelerated to $V = 0.9\,c$ relative to the rest frame and then is further accelerated to $v' = 0.9\,c$ in the moving, particle-associated frame, the resulting speed will be $1.8\,c/1.81 < c$ rather than $1.8\,c$. It is apparent that the speed of light cannot be exceeded. The light speed is the maximum possible speed at which interactions can be transferred in nature.

► **Spacetime interval. Casuality.** The Lorentz transformations preserve neither the time interval nor the length of a spatial segment. However, it can be shown that the following quantity is preserved under the Lorentz transformations:

$$s_{12}^2 = (c\Delta t)^2 - (\Delta x)^2 - (\Delta y)^2 - (\Delta z)^2 = (c\Delta t)^2 - (\Delta \mathbf{r})^2. \qquad \text{(P1.10.2.4)}$$

The quantity s_{12} is called the *spacetime interval* between events 1 and 2 ($\Delta t = t_2 - t_1$ and $\Delta\mathbf{r} = \mathbf{r}_2 - \mathbf{r}_1$).

If $s_{12}^2 > 0$, the spacetime interval is called *time-like*. In this case, there is an inertial frame where $\Delta\mathbf{r} = \mathbf{0}$, which means that the events occur at the same place but at different times. Such events can have a cause–effect relationship.

If $s_{12}^2 < 0$, the spacetime interval between events is called *space-like*. In this case, there is an inertial frame in which $\Delta t = 0$, so that the events occur simultaneously at different locations in space. Such events cannot have a causal relationship. The condition $c|\Delta t| < |\Delta\mathbf{r}|$, or $c|t_2 - T_1| < |\mathbf{r}_2 - \mathbf{v}_1|$, means that a light beam emitted at the instant of the earlier event (at t_1) from the point $\mathbf{r}_1$ cannot reach the point $\mathbf{r}_2$ by the instant t_2. Events separated from event 1 by time-like intervals represent its *absolute past* (if $t_2 - t_1 < 0$) or *absolute future* (if $t_2 - t_1 > 0$); the sequence of events is the same in all inertial frames. The sequence of events separated by a space-like interval can be different in different inertial frames.

► **Lorentz four-vectors.** A quadruple of scalar quantities $(A_x, A_y, A_z, A_\tau) = (\mathbf{A},\ A_\tau)$ that are transformed, when passing from frame K to frame K', in the same way as (x, y, z, ct), or (see (P1.10.1.1))

$$A_x{}' = \frac{A_x - (V/c)A_\tau}{\sqrt{1 - V^2/c^2}}, \quad A_y{}' = A_y, \quad A_z{}' = A_z, \quad A_\tau{}' = \frac{A_\tau - (V/c)A_x}{\sqrt{1 - V^2/c^2}}, \qquad \text{(P1.10.2.5)}$$

is called a *Lorentz four-dimensional vector* (or, for short, *four-vector* or *4-vector*). The numbers A_x, A_y, and A_z are called the spatial components of the 4-vector and A_τ is called its time component. The sum of two 4-vectors and the product of a 4-vector by a scalar number are also 4-vectors. The quantity $A^2 = A_\tau^2 - \mathbf{A}^2$, analogous to the spacetime interval, and also the scalar product $A_\tau B_\tau - \mathbf{A}\cdot\mathbf{B}$ are preserved in changing from one inertial frame to another. A physical equation written as an equality of two 4-vectors remains valid in all inertial frames.

P1.10.3. STR Dynamics

► **Momentum and energy in special relativity.** The velocity components are not transformed in the same way as the components of a 4-vector (cf. equations (P1.10.2.3) and (P1.10.2.5)), since both the numerator and the denominator are transformed in the expression $\mathbf{v} = d\mathbf{r}/dt$. Consequently, the quantity $\sum_j m_j\mathbf{v}_j$, corresponding to the classical definition of momentum, cannot be preserved in all inertial frames. The relativistic 4-vector of momentum is defined as

$$\mathbf{p} = m\frac{d\mathbf{r}}{d\tau} = \frac{m}{\sqrt{1-v^2/c^2}}\frac{d\mathbf{r}}{dt}, \qquad p_\tau = m\frac{d(ct)}{d\tau} = \frac{mc}{\sqrt{1-v^2/c^2}},$$

where $d\tau = dt\,\sqrt{1-v^2/c^2}$ is the infinitesimal change in the proper time of the particle (see (P1.10.2.2)), i.e., the time measured in an inertial frame whose velocity coincides with that of the particle at the given instant ($d\tau$ is independent of which inertial frame the particle is observed from). The spatial components of the 4-vector make up the *relativistic momentum*

$$\mathbf{p} = \frac{m\mathbf{v}}{\sqrt{1-v^2/c^2}}, \tag{P1.10.3.1}$$

while the time component p_τ turns out to be equal to E/c, where E is the *relativistic energy* of the particle:

$$E = \frac{mc^2}{\sqrt{1-v^2/c^2}}. \tag{P1.10.3.2}$$

The 4-vector $(\mathbf{p}, E/c)$ is called the *momentum-energy four-vector* or the *four-momentum*. It is noteworthy that the relativistic energy and momentum are linked by the simple relation

$$\mathbf{p} = \frac{E\mathbf{v}}{c^2}. \tag{P1.10.3.3}$$

In accordance with (P1.10.2.5), in changing from one inertial frame to another, the energy and momentum are transformed as

$$p_x{}' = \frac{p_x - VE/c^2}{\sqrt{1-V^2/c^2}}, \quad p_y{}' = p_y, \quad p_z{}' = p_z, \quad E' = \frac{E - Vp_x}{\sqrt{1-V^2/c^2}}. \tag{P1.10.3.4}$$

The relativistic energy of a particle is nonzero at $v = 0$; it consists of the rest energy, mc^2, and the kinetic energy,

$$E = \frac{mc^2}{\sqrt{1-v^2/c^2}} = mc^2 + E_\mathrm{k}. \tag{P1.10.3.5}$$

Note that for $v/c \ll 1$, the relativistic kinetic energy reduces to the classical kinetic energy $E_\text{k} = mv^2/2$. Since the quantity $(E/c)^2 - p^2$ is conserved, it can be calculated in a frame where the particle is at rest at the given instant:

$$\frac{E^2}{c^2} - p^2 = m^2c^2 \qquad \text{or} \qquad E^2 - p^2c^2 = m^2c^4. \tag{P1.10.3.6}$$

For particles with zero mass (e.g., photons), the energy–momentum relation becomes

$$E = pc \tag{P1.10.3.7}$$

(see also (P1.10.3.3)). Substituting $E = mc^2 + E_\text{k}$ into (P1.10.3.6) yields a convenient relation between momentum and kinetic energy:

$$p^2c^2 = E_\text{k}(E_\text{k} + 2mc^2).$$

► **Inelastic collision. Relation between energy and mass.** Let us write down the law of conservation of relativistic energy for a perfectly inelastic collision of two particles of mass m each that moved toward each other with identical speeds v. We have

$$\frac{mc^2}{\sqrt{1 - v^2/c^2}} + \frac{mc^2}{\sqrt{1 - v^2/c^2}} = Mc^2.$$

It is apparent that the mass M of the combined particle is larger than the total mass of the initial particles. The increase in the internal energy at the inelastic collision by ΔE resulted in a mass increase of $\Delta E/c^2$. This example illustrates the general Einstein relationship between the relativistic energy of a resting body and its mass:

$$E = mc^2. \tag{P1.10.3.8}$$

Relativistic energy includes all kinds of energy.

Example 1. Suppose the energy of a body at rest equals E. Find the momentum of the body in a reference frame moving with a speed $-v$.

Solution. In accordance with the relativistic transformation formulas (P1.10.3.4), the momentum equals

$$\mathbf{p}' = (E'/c^2)\mathbf{v} = \frac{(E/c^2)\mathbf{v}}{\sqrt{1 - v^2/c^2}}.$$

It is seen that we have obtained the formula for relativistic momentum with mass $m = E/c^2$.

Example 2. Accelerators with colliding particle beams. Suppose that in order to achieve the threshold energy of a nuclear reaction, the particles in colliding beams must be accelerated to a kinetic energy αmc^2. To what kinetic energy must a single particle be accelerated if the other particle is in a stationary target?

Solution. In the nonrelativistic case, the energy in a center-of-mass frame equals half the energy of the oncoming particle. It is this energy that can be spent to the reaction, while the other half is inaccessible— it remains as kinetic energy of the system. In the relativistic (an especially ultrarelativistic) limit, the picture is cardinally different. Compute the energy of the moving particle (the other particle is at rest). Write the energy-momentum invariance condition for $E^2 - p^2c^2$. In a center-of-mass frame, we have $E = 2\alpha mc^2 + 2mc^2$ and $p = 0$. In a moving inertial frame where one of the particles is at rest, we have $E = E_1 + mc^2$ and $p = p_1$, with E_1 and p_1 being the energy and momentum of the moving particle. On rearranging and taking into account the identity $E_1^2 - p_1^2c^2 = m^2c^4$, we find the kinetic energy of the oncoming particle as $E_1 - mc^2 = 2mc^2\alpha(\alpha + 2)$. For example, if $\alpha = 100$, we find that one particle must be accelerated to 20,400 mc^2. Approximately, $1/100$ of the particle energy is available for the reaction.

► **Basic law of relativistic dynamics.** The force exerted on a particle equals, just as in the case of classical mechanics, the time derivative of the momentum

$$\mathbf{F} = \frac{d\mathbf{p}}{dt}. \qquad \text{(P1.10.3.9)}$$

However, the relativistic momentum (P1.10.3.1) is different from the classical one. Under the action of the load applied, the momentum can increase unboundedly. However, as seen from definition (P1.10.3.1), the speed will be less than c. The work done by the force (P1.10.3.9),

$$\begin{aligned}\int \mathbf{F}\cdot d\mathbf{r} &= \int \frac{d\mathbf{p}}{dt}\cdot \mathbf{v}\,dt = \int \mathbf{v}\cdot d\mathbf{p}\\ &= \int \sqrt{1-v^2/c^2}\,\frac{\mathbf{p}\cdot d\mathbf{p}}{m} = \int \sqrt{1-v^2/c^2}\,\frac{E\,dE}{mc^2} = \int dE,\end{aligned}$$

equals the change in the kinetic energy. Here we have used formulas (P1.10.3.1) and (P1.10.3.2) and also $\mathbf{p}\cdot d\mathbf{p} = E\,dE/c^2$ (see (P1.10.3.6)).

Chapter P2

Molecular Physics and Thermodynamics

P2.1. Basic Principles and Definitions

P2.1.1. Two Approaches to Studying Matter

► **Thermodynamic approach.** The *thermodynamic approach* of studying substances consists of establishing links and relations between experimentally determined (phenomenological) parameters (called *thermodynamic parameters*) based on several postulates (*laws of thermodynmics*).

► **Statistical approach.** The *statistical approach* relies on kinetic-molecular postulates on the structure of substance (*fundamentals of kinetic-molecular theory*). These postulates include the following:

1. All bodies consist of a huge number of tiny particles—atoms and molecules.
2. These molecules are in constant random motion.
3. The molecules interact with one another: they experience attractive forces at large distances and repulsive forces at small enough distances.

The thermodynamic parameters are calculated within the framework of a specific model of internal structure of substance (i.e., the model of motion and interaction of atoms and molecules) by averaging over a huge number of states of the system. Statistical physics employs methods of probability theory and mathematical statistics. The classical theory relies on the classical laws of molecular motion, while quantum statistics relies on the laws of quantum mechanics.

► **Amount of substance. Mole.** The amount of substance in a system—or the number of constituting structural units, atoms and molecules—is measured in *moles*. One mole of any substance contains a certain number of molecules, called *Avogadro's number* (or the *Avogadro constant*) and equal to the number of atoms in 12 g of carbon-12. Avogadro's number equals $N_\mathrm{A} \approx 6.02 \times 10^{23}$ mol^{-1}. The number of moles in the system is expressed as

$$\nu = \frac{N}{N_\mathrm{A}} = \frac{m}{\mu}, \qquad \text{(P2.1.1.1)}$$

where N is the number of molecules in the system, $m = m_0 N$ is the mass of the system, m_0 being the mass of a single molecule, and $\mu = m_0 N_\mathrm{A}$ is the molar mass of the substance.

P2.1.2. Equation of State

► **Equilibrium states.** A thermodynamic system that is kept under unchanged external conditions comes to an *equilibrium state*, where there are no fluxes of any kind (e.g., mass or energy fluxes). The thermodynamic parameters of the equilibrium state (pressure p, temperature T, volume V, density ρ, molar mass μ, etc.) are related by an *equation of state*. For example, the *ideal gas law* (also known as the *Clapeyron–Mendeleev equation*), which is the equation of state of an ideal gas, has the form

$$pV = \nu RT \qquad \text{or} \qquad pV = NkT, \qquad \text{(P2.1.2.1)}$$

where $R \approx 8.31\,\mathrm{J/(mol\,K)}$ is the *gas constant* and $k = R/N_\mathrm{A} \approx 1.38 \times 10^{-23}\,\mathrm{J/K}$ is the *Boltzmann constant*. This equation was obtained empirically and it describes well the behavior of thin real gases (see Subsection P2.5.2). The *van der Waals equation*,

$$(V - \nu b)\Big(p + \frac{a\nu^2}{V^2}\Big) = \nu RT, \qquad \text{(P2.1.2.2)}$$

is an equation of state that provides good approximation to the behavior of dense real gases (see Section P2.6).

A process of changing the state of a system is called *equilibrium* (also *quasi-equilibrium* or *quasistatic*) if it occurs so slowly that every intermediate state of the system can be treated as equilibrium. Equilibrium processes are typically *reversible* (i.e., can be made to pass through all their intermediate states in order); however, irreversible equilibrium processes are possible (e.g., for systems with memory). In what follows, when speaking of an equilibrium process we imply a reversible equilibrium process.

► **Simple thermodynamic system.** A homogeneous and isotropic thermodynamic system whose chemical composition does not change is called (*thermodynamically*) *simple*. Examples of simple systems are one-component (pure) gases and liquids. A simple system has two degrees of freedom, which means that only two of its thermodynamic parameters are independent. Equilibrium states of a simple system can be represented by points in a plane (e.g., in coordinates p and V) and equilibrium processes, by lines in this plane. The work done by a simple system against external forces equals

$$\delta A = p\,dV, \qquad A = \int_{V_1}^{V_2} p(V)\,dV, \qquad \text{(P2.1.2.3)}$$

where the relationship $p(V)$ is called a *process equation*. Since the work is not a function of state, the infinitesimal work increment is denoted by δA, in order to distinguish it from the infinitesimal increment of a function (differential).

If any three parameters of a simple system are related to one another, due to an equation of state, their derivatives are also related by an equation. For example, expressing the infinitesimal increment of T in terms of those of p and V, we have $dT = (\partial T/\partial V)_p\,dV + (\partial T/\partial p)_V\,dp$. By applying this expression to isothermal process ($dT = 0$), we obtain

$$\Big(\frac{\partial V}{\partial T}\Big)_p \Big(\frac{\partial T}{\partial p}\Big)_V \Big(\frac{\partial p}{\partial V}\Big)_T = -1.$$

This equation relates three coefficients

$$\alpha = \frac{1}{V}\Big(\frac{\partial V}{\partial T}\Big)_p \quad (\textit{thermal volume expansion coefficient}),$$

$$\beta = \frac{1}{p}\Big(\frac{\partial p}{\partial T}\Big)_V \quad (\textit{thermal pressure coefficient}),$$

$$K = -V\Big(\frac{\partial p}{\partial V}\Big)_T \quad (\textit{isothermal bulk modulus}).$$

► **Nonequilibrium systems.** *Equilibrium thermodynamics* deals with equilibrium states and processes. It can judge the *direction of nonequilibrium processes* between the initial and final equilibrium states but cannot provide quantitative characterization of these processes. Nonequilibrium systems are studied by *physical kinetics* and *nonequilibrium thermodynamics*. Note that the time in which a system comes to equilibrium (*relaxation time*) decreases with decreasing system size, and therefore the term *local equilibrium* in a small portion of a nonequilibrium system makes sense. Consequently, it is meaningful to speak of local thermodynamic parameters (functions of state) that vary from point to point in a nonequilibrium system (e.g., temperature $T(\mathbf{r})$).

An important role in studying nonequilibrium systems is played by the notions of *flux* of a physical quantity (e.g., the number of molecules, mass, momentum, energy, charge, etc.) through a given surface and *flux density* at a given point in space.

For instance, energy flux W equals the amount of energy transferred through a surface per unit time (measured in J/s, or W). A *flux density* is a vector quantity that characterizes the direction and intensity of transfer of a physical quantity through a given point in space. For instance, energy flux density **w** equals in magnitude to the ratio of the energy flux ΔW through a small surface to the area ΔS of this surface (measured in $\mathrm{W/m^2}$) in the limit $\Delta S \to 0$. Among all small surfaces through the given point, one must take one for which the above ratio is maximum. The vector **w** is taken to be perpendicular to this surface and pointing in the direction of the energy transfer. The energy flux through a given surface equals $W = \int \mathbf{w}\,d\mathbf{s}$, where $d\mathbf{s} = \mathbf{n} \cdot ds$, with **n** being the positive unit normal vector at the given point of the surface. Note that in electrodynamics (see Subsection P3.7.1), the flux of electric charge is called the electric current I and the flux density, the current density **j**.

A state of a nonequilibrium system is called *stationary* if the flux densities of all physical quantities at all points are time independent. Recall that in an equilibrium state, there are no fluxes, that is, the flux densities at all points are zero.

P2.2. First Law of Thermodynamics

P2.2.1. Quantity of Heat. Internal Energy

► **Quantity of heat.** Unlike mechanical energy, which can only change through work, internal energy can change both due to work and due to contact with bodies having different temperatures (in the process of heat exchange). The amount of energy absorbed or lost by a system in a thermal contact is called the *quantity of heat* or just *heat* and denoted Q. Heat is considered positive if energy is received by the system and negative if it is given off.

In a thermal contact, energy is transferred from a body with a higher temperature to a body with a lower temperature. Any temperature scale must satisfy this property. Empirical temperature scales are based on indirect measurements, that is, on changes in parameters monotonically dependent on temperature. A gas scale of temperatures relies on the equation of state of the ideal gas (P2.1.2.1). A thermodynamic, or absolute scale, is based on the second law of thermodynamics.

► **Internal energy.** From the viewpoint of classical kinetic-molecular theory, the internal energy U of a thermodynamic system equals the sum of the kinetic energy of motion of all its molecules and the potential energy of their interaction. The internal energy, $U = U(V, T, \dots)$, is a function of state of a thermodynamic system;* it is the most important characteristic of the system.

Thermodynamics must define any quantity phenomenologically, regardless of our knowledge about the internal structure of the substance. The concept of an *adiabatic envelope* can be used to see that this is possible in principle. The adiabatic envelope of thermodynamic system allows the shape of the system to be changed and work on the system to be done but excludes thermal exchange of the system with external bodies. In this case, the work done by the external forces, A^{e}, as the system performs a transition from state 1 to state 2 is independent of the transition process and is only dependent on the initial and final states. This allows us to define the internal energy difference as $U_2 - U_1 = A^{\mathrm{e}}(1 \to 2)$.

P2.2.2. First Law of Thermodynamics

The general law of conservation of energy, which takes into account thermal exchange and internal energy, reads

$$\Delta E_{\text{mech}} + \Delta U = A^{\mathrm{e}} + Q. \qquad \text{(P2.2.2.1)}$$

It states that the change in the total (mechanical plus internal) energy equals the work done by external forces and the quantity of heat received by the system in thermal exchange with external bodies. Sometimes, the law of conservation of energy is formulated as the impossibility of creating a *perpetual motion machine of the first kind* (that would produce energy from nothing). The *first law of thermodynamics* is the special case of the law of conservation of energy as applied to thermodynamic systems, whose mechanical energy does not change. In addition, in thermodynamics it is customary to use the work done by the system against external forces: $A = -A^{\mathrm{e}}$. We have

---

* The relationship $U = U(V, T, \dots)$ is called a *caloric equation of state*, in contract to $p = p(V, T)$, called a *thermal equation of state*.

$$Q = \Delta U + A, \qquad \text{(P2.2.2.2)}$$

which means that the heat supplied to a thermodynamic system is spent to change its internal energy and produce work against external forces.

► **First law of thermodynamics for a simple system. Heat capacity.** Using equation (P2.1.2.3), let us write out the first law of thermodynamics for a simple system that has received an infinitesimal quantity of heat:

$$\delta Q = dU + p\,dV. \qquad \text{(P2.2.2.3)}$$

The ratio of δQ to the temperature increment dT is called the *heat capacity* of the system in the equilibrium process being considered. Heat capacity is measured in J/K and denoted by C. We have

$$C\,dT = dU + p\,dV. \qquad \text{(P2.2.2.4)}$$

Considering U in (P2.2.2.4) to be a function of two variables (V,T), we can write

$$dU = \left(\frac{\partial U}{\partial T}\right)_V dT + \left(\frac{\partial U}{\partial V}\right)_T dV = C_V\,dT + \left(\frac{\partial U}{\partial V}\right)_T dV, \qquad \text{(P2.2.2.5)}$$

where $C_V = \left(\frac{\partial U}{\partial T}\right)_V$ is the *heat capacity at constant volume* (see equation (P2.2.2.4)). So we have

$$C\,dT = C_V\,dT + \left[p + \left(\frac{\partial U}{\partial V}\right)_T\right] dV. \qquad \text{(P2.2.2.6)}$$

It can be seen that the heat capacity for a process $V(T)$ depends on the value of the derivative dV/dT. Since the parameters (V,T) can be varied independently, this derivative and, hence, the heath capacity at a given point can take any value.

► **Enthalpy. The Joule–Thomson process.** If the state of a system is changed as an equilibrium process under a constant pressure, then the heat supplied can be expressed as

$$Q = \Delta U + p\Delta V = \Delta(U + pV) = \Delta H \qquad (p = \text{const}). \qquad \text{(P2.2.2.7)}$$

The quantity $H = U + pV$ is called the *enthalpy* of the system. So the heat supplied equals the enthalpy difference at the final and initial states. Enthalpy is also used to describe the *Joule–Thomson process* (also called a *throttling process*), where a substance is forced through a porous wall without heat exchange with the environment. This process is used to achieve very low temperatures. Enthalpy is conserved in the Joule–Thomson process: $U_1 + p_1V_1 = U_2 + p_2V_2$.

► **Thermodynamic cycle.** A thermodynamic cycle is a series of thermodynamic processes in which a system eventually returns to its initial equilibrium state. At some stage, the system absorbs a quantity of heat Q_1 from higher-temperature bodies (*hot reservoir*) and at another stage, it gives up some heat Q_2 to lower-temperature bodies (*cold reservoir*). (This follows from the second law of thermodynamics; see Section P2.3.) For a heat engine, a device that runs on a thermodynamic cycle, its *thermal efficiency* is the number defined as

$$\eta = \frac{A}{Q_1} = \frac{Q_1 - Q_2}{Q_1} = 1 - \frac{Q_2}{Q_1}, \qquad \text{(P2.2.2.8)}$$

where A is the net work done in one cycle. In a thermodynamic cycle, $\Delta U = 0$, and hence $Q_1 - Q_2 = A$.

P2.2.3. First Law of Thermodynamics for an Ideal Gas

► **Internal energy of an ideal gas**. The internal energy of an ideal gas depends only on its temperature, so that $U(p_1, V_1, T) = U(p_2, V_2, T)$. There is experimental evidence supporting this statement.

1. When a gas expands into a void space inside a rigid adiabatic container, both the work done by the gas, A, and the heat absorbed, Q, are zero, and hence $\Delta U = 0$. It was found (experiments by Gay-Lussac and Joule) that in this non-equilibrium process, the temperature of ideal gases does not change.

2. The temperature of an ideal gas does not change in the Joule–Thomson process.

The second law of thermodynamics allows us to prove that $(\partial U/\partial V)_T = 0$ based on the thermic equation of state (P2.1.2.1).

From equations (P2.2.2.4) and (P2.2.2.5) we find the increment in the internal energy and the first law of thermodynamics for an ideal gas:

$$dU = C_V\,dT, \qquad \delta Q = C_V\,dT + p\,dV. \tag{P2.2.3.1}$$

Experiments show that C_V is independent of T in a wide range of temperatures. Hence, we can write $U = C_V T + \text{const}$.

► **Processes in an ideal gas.** Consider a few examples to illustrate the application of the first law of thermodynamics to specific equilibrium processes in an ideal gas.

Example 1. Isothermal process ($dT = 0$). In this case, $dU = 0$. Hence,

$$\delta Q = p\,dV, \qquad Q = A = \int_{V_1}^{V_2} p(V)\,dV = \nu RT \ln\left(\frac{V_2}{V_1}\right). \tag{P2.2.3.2}$$

The heat capacity of this process can be considered infinitely large.

Example 2. Isobaric process ($dp = 0$). Introducing the *heat capacity at constant pressure* and taking into account the equation of state (P2.1.2.1), we get

$$C_p\,dT = C_V\,dT + p\,dV = C_V\,dT + \nu R\,dT.$$

Dividing by dT gives the relation between the heat capacities (*Mayer's relation*):

$$C_p = C_V + \nu R, \qquad c_p = c_V + \frac{R}{\mu}, \qquad C_p^{\rm m} = C_V^{\rm m} + R, \tag{P2.2.3.3}$$

where $c = C/m$ is the *specific heat capacity* and $C^{\rm m} = C/\nu$ is the *molar heat capacity* of the gas (measured in J/(kg K) and J/(mol K), respectively).

Example 3. Adiabatic process. If an equilibrium process occurs without heat supply ($\delta Q = 0$), then

$$C_V\,dT = -p\,dV \quad\Longrightarrow\quad \nu C_V^{\rm m}\,dT = -\frac{\nu RT}{V}\,dV \quad\Longrightarrow\quad \frac{dT}{T} = -\frac{R}{C_V^{\rm m}}\frac{dV}{V}.$$

Integrating yields the equation of the adiabatic process (*Poisson's equation*):

$$TV^{\gamma-1} = \text{const} \qquad \text{or} \qquad pV^{\gamma} = \text{const}, \tag{P2.2.3.4}$$

where the dimensionless parameter $\gamma = C_p/C_V = 1 + (R/C_V^{\rm m})$ is called the *adiabatic index*. Using Mayer's relation (P2.2.3.3), we can express the molar heat capacities in terms of γ as

$$C_V^{\rm m} = \frac{R}{\gamma - 1}, \qquad C_p^{\rm m} = \frac{\gamma R}{\gamma - 1}.$$

Example 4. Polytropic process. A thermodynamic process with constant heat capacity ($C = \text{const}$) is called polytropic. We have

$$C\,dT = C_V\,dT + p\,dV \quad\Longrightarrow\quad (C_V - C)\,dT = -p\,dV.$$

Proceeding in the same manner as for the adiabatic process, we arrive at the *polytropic process equation*

$$pV^n = \text{const},$$

where $n = 1 + \dfrac{R}{C_V^{\rm m} - C^{\rm m}} = \dfrac{C_p - C}{C_V - C}$ is the *polytropic index.*

It can be verified that the above thermodynamic processes are special cases of a polytropic process—isochoric with $n = \infty$, isobaric with $n = 0$, isothermal with $n = 1$, and adiabatic with $n = \gamma$.

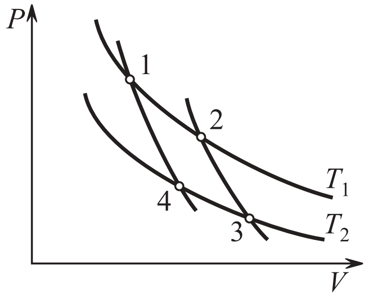

Figure P2.1 A Carnot cycle consists of two isothermal processes (1 to 2 and 3 to 4) and two adiabatic processes (2 to 3 and 4 to 1).

Example 5. Carnot cycle. A Carnot cycle is a thermodynamic cycle consisting of two isothermal processes (at temperatures T_1 and T_2 with $T_1 > T_2$) and two adiabatic processes as shown in Fig. P2.1.

From equation (P2.2.3.2) we have

$$Q_1 = \nu R T_1 \ln\left(\frac{V_2}{V_1}\right), \qquad Q_2 = \nu R T_2 \ln\left(\frac{V_3}{V_4}\right).$$

From Poisson's equation (P2.2.3.4) we have

$$T_1 V_1^{\gamma-1} = T_2 V_4^{\gamma-1},$$
$$T_1 V_2^{\gamma-1} = T_2 V_3^{\gamma-1}.$$

It follows that $V_2/V_1 = V_3/V_4$. Hence, the thermal efficiency is

$$\eta = 1 - \frac{T_2}{T_1}. \qquad \text{(P2.2.3.5)}$$

This means that the thermal efficiency of a Carnot cycle depends only on the cold-to-hot reservoir temperature ratio.

P2.3. Second Law of Thermodynamics

P2.3.1. Formulations

Below are two most common formulations of the second law of thermodynamics:

1. It is impossible to construct an engine that would convert 100% of heat extracted from a heat reservoir into work in a cyclic process (formulation by William Thomson—Lord Kelvin). It is the same to say that it is impossible to create a *perpetual motion machine of the second kind* (that would produce work at the expense of solely the internal energy of a heat reservoir).

2. It is impossible to construct a refrigerator that would produce no other effect than the transfer energy from a cooler body to a hotter one (formulation by Rudolf Clausius).

The Thomson and Clausius formulations are equivalent.

P2.3.2. Carnot's Theorem

In general, a *Carnot cycle* is a thermodynamic cycle in which the working substance (of a heat engine) absorbs heat from a hot reservoir (at a constant temperature T_1) and gives up heat to a cold reservoir (at a constant temperature T_2).

Carnot's theorem states that the thermal efficiency of an arbitrary Carnot cycle cannot exceed that of any reversible Carnot cycle operating at the same temperatures T_1 and T_2. It immediately follows that the thermal efficiency of a reversible Carnot cycle depends on T_1 and T_2 only and is independent of the working substance nature.

Let us sketch the proof of Carnot's theorem. Assume that the thermal efficiency of the reversible heat engine is less than that of the irreversible one. Let us choose the amount of the working substance in the reversible engine such that the work done in one cycle is the same as the work done by the irreversible engine. Using (P2.2.2.8) and the above assumption, we can write the thermal efficiency inequality as $A/Q_1^{\rm rev} < A/Q_1^{\rm irrev}$, or $Q_1^{\rm rev} > Q_1^{\rm irrev}$. Now let us revert the operation of the reversible engine so that its work is consumed by the irreversible engine. In one cycle, the combined engine produces zero work and the hot reservoir receives the energy $Q_1^{\rm rev} - Q_1^{\rm irrev} > 0$ completely extracted from the cold reservoir. We have come to a conclusion that contradicts the Clausius formulation of the second law.

Since we know the thermal efficiency of a Carnot engine, the one that runs on an ideal gas (see (P2.2.3.5)), we can rewrite Carnot's theorem as

$$\frac{Q_1 - Q_2}{Q_1} \le \frac{T_1 - T_2}{T_1} \qquad \text{or} \qquad \frac{Q_1}{T_1} - \frac{Q_2}{T_2} \le 0. \tag{P2.3.2.1}$$

The equality corresponds to a reversible Carnot cycle.

► **Thermodynamic temperature scale.** Carnot's theorem allows us to introduce a temperature scale that does not depend on the properties of specific bodies involved. The temperature ratio of two bodies can be determined by connecting them with a reversible Carnot engine. Since the ratio Q_1/Q_2 depends only on the two temperatures, it can be taken to be equal to the ratio of the thermodynamic temperatures: $\theta_1/\theta_2 = Q_1/Q_2$. As seen from (P2.3.2.1), the ratio of the thermodynamic temperatures equals that of the ideal gas temperatures (in the range where the gas scale is defined).

P2.3.3. Calculation of the Internal Energy

► **Relation between U and V.** The second law of thermodynamics allows us to derive the important formula for the internal energy of a simple system

$$\left(\frac{\partial U}{\partial V}\right)_T = T\left(\frac{\partial p}{\partial T}\right)_V - p, \tag{P2.3.3.1}$$

which cannot be obtained based on the first law only.

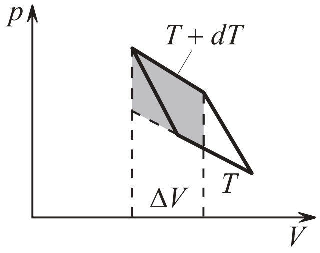

Figure P2.2. Infinitesimal Carnot cycle.

Let us derive formula (P2.3.3.1) from Carnot's theorem. Consider a very small (infinitesimal) reversible Carnot cycle for a simple system and plot it in the pV-coordinates. The work done by the system in one cycle, equal to the area of the small parallelogram (Fig. P2.2), will not change if we replace the adiabatic curves by vertical segments, whose lengths equal $\left(\frac{\partial p}{\partial T}\right)_V \Delta T$. Multiplying by the height ΔV gives $\delta A = \left(\frac{\partial p}{\partial T}\right)_V \Delta T \Delta V$. The heat absorbed at the top isotherm is equal to $\delta Q_1 = \Delta U + p\,dV = \left(\frac{\partial U}{\partial V}\right)_T \Delta V + p\,\Delta V$, where ΔU has been substituted by its expression (P2.2.2.5) at constant temperature. From Carnot's theorem and equation (P2.3.2.1) we get

$$\frac{\delta A}{\delta Q_1} = \frac{\Delta T}{T} \quad\Longrightarrow\quad \frac{\left(\dfrac{\partial p}{\partial T}\right)_V \Delta T \Delta V}{\left[\left(\dfrac{\partial U}{\partial V}\right)_T + p\right]\Delta V} = \frac{\Delta T}{T},$$

which immediately leads to (P2.3.3.1).

Below are a few examples illustrating the application of formula (P2.3.3.1).

Example 1. Internal energy of an ideal gas. Let us substitute the equation of state $p = \frac{1}{V}\nu RT$ into (P2.3.3.1) to obtain $\left(\frac{\partial U}{\partial V}\right)_T = 0$, which means that the internal energy is independent of volume.

Example 2. Internal energy of a van der Waals gas. Expressing pressure from the equation of state (P2.1.2.2) and substituting into (P2.3.3.1), we obtain $\left(\frac{\partial U}{\partial V}\right)_T = \frac{a\nu^2}{V^2}$. It follows that

$$dU = C_V\,dT + \frac{a\nu^2}{V^2}\,dV.$$

Furthermore, we have

$$\left(\frac{\partial C_V}{\partial V}\right)_T = \frac{\partial}{\partial V}\left[\left(\frac{\partial U}{\partial T}\right)_V\right] = \frac{\partial}{\partial T}\left[\left(\frac{\partial U}{\partial V}\right)_T\right] = \frac{\partial}{\partial T}\left(\frac{a\nu^2}{V^2}\right)_V = 0,$$

which means that C_V is independent of volume. For the temperature range where C_V is weakly dependent on T, we can write

$$U = C_V T - \frac{a\nu^2}{V}. \tag{P2.3.3.2}$$

Example 3. General formula for $C_p - C_V$. Substituting (P2.3.3.1) into (P2.2.2.6) and taking pressure to be constant, we find

$$C_p - C_V = T\left(\frac{\partial p}{\partial T}\right)_V\left(\frac{\partial V}{\partial T}\right)_p = -T\left(\frac{\partial p}{\partial V}\right)_T\left(\frac{\partial V}{\partial T}\right)_p^2 \geq 0.$$

(We have used the relation for the derivatives given at the end of Subsection P2.1.2.) This inequality follows from the condition of mechanical stability $\left(\frac{\partial p}{\partial V}\right)_T \leq 0$.

P2.4. Entropy

P2.4.1. Clausius Inequality

Inequality (P2.3.2.1) is a special case of the *Clausius inequality*, which holds for any thermodynamic cycle. If a system absorbs, in a thermodynamic process, some quantities of heat $Q_1, \ldots, Q_N$ from external reservoirs having temperatures $T_1^{\rm e}, \ldots, T_N^{\rm e}$, then the following inequality holds:

$$\sum_{i=1}^{N} \frac{Q_i}{T_i^{\rm e}} \leq 0 \qquad \text{or} \qquad \oint \frac{\delta Q}{T^{\rm e}} \leq 0. \tag{P2.4.1.1}$$

For a reversible process, the inequality becomes equality and the temperature of the reservoir with which the system is in thermal contact at the given point of the cycle is equal to the temperature of the system: $T^{\rm e} = T$. In this case,

$$\oint_{\rm rev} \frac{\delta Q}{T} = 0. \tag{P2.4.1.2}$$

Equation (P2.4.1.2) serves to define another function of state—entropy.

P2.4.2. Definition of Entropy

The Clausius equation for a reversible cycle (P2.4.1.2) can be reformulated as the condition for the integral

$$\int_A^B \frac{\delta Q}{T}$$

to be independent of the equilibrium path by which the system passes from state A to state B. This allows one to define a state variable, *entropy*, as

$$S_B - S_A = \int_A^B \frac{\delta Q}{T}, \qquad dS = \left(\frac{\delta Q}{T}\right)_{\text{rev}}. \tag{P2.4.2.1}$$

To be precise, this relation defines the entropy difference between two states. If there is no heat supply in an equilibrium process, entropy does not change; so an adiabatic process can be called isentropic. For a simple system in an equilibrium process, the first law of thermodynamics (P2.2.2.3) acquires the form

$$T\,dS = dU + p\,dV. \tag{P2.4.2.2}$$

Since $\delta Q = T\,dS$ for any equilibrium process, it is convenient to plot equilibrium processes and cycles in the TS-coordinates, where the area under the curve $T(S)$ equals the quantity of heat received. For example, a Carnot cycle is represented by a rectangle in TS-coordinates.

► Examples of entropy calculations.

Example 1. Process with constant heat capacity. The entropy change corresponding to the temperature change from T_1 to T_2 equals

$$S_2 - S_1 = \int_{T_1}^{T_2} \frac{C\,dT}{T} = C\ln\left(\frac{T_2}{T_1}\right). \tag{P2.4.2.3}$$

Example 2. Entropy of an ideal gas. Substituting the internal energy equation for an ideal gas (P2.2.3.1) into (P2.4.2.2) and taking into account the equation of state $pV = \nu RT$, we obtain

$$\begin{aligned} dS &= \nu C_V^{\text{m}}\frac{dT}{T} + \nu R\frac{dV}{V}, \\ S_2 - S_1 &= \nu\left[C_V^{\text{m}}\ln\left(\frac{T_2}{T_1}\right) + R\ln\left(\frac{V_2}{V_1}\right)\right]. \end{aligned} \tag{P2.4.2.4}$$

Sometimes, entropy is written as $S = \nu(C_V^{\text{m}}\ln T + R\ln V)$, bearing in mind that an entropy difference actually arises in applications.

Example 3. Entropy of a van der Waals gas. Substituting (P2.3.3.2) into (P2.4.2.2) and taking into account the equation of state (P2.1.2.2), we obtain

$$\begin{aligned} dS &= \nu C_V^{\text{m}}\frac{dT}{T} + \frac{a\nu^2}{T}\frac{dV}{V^2} + \frac{p}{T}dV = \nu C_V^{\text{m}}\frac{dT}{T} + \frac{\nu R\,dV}{V - \nu b}, \\ S &= \nu\left[C_V^{\text{m}}\ln T + R\ln(V - \nu b)\right]. \end{aligned}$$

P2.4.3. Direction of Non-Equilibrium Processes in a Thermally Insulated System

Consider a non-equilibrium process that takes a system from an equilibrium state 1 to an equilibrium state 2. Let us set up a cyclic process by returning from 2 to 1 using any equilibrium process. Writing down the Clausius inequality (P2.4.1.1) for this cycle and taking into account the entropy definition (P2.4.2.1) for the equilibrium process, we get

$$\int_1^2 \frac{\delta Q}{T^{\text{e}}} \le S_2 - S_1. \tag{P2.4.3.1}$$

If the non-equilibrium process occurs in an adiabatic envelope, then the left-hand side vanishes and then

$$S_2 \geq S_1, \tag{P2.4.3.2}$$

which means that entropy does not decrease in any process without heat supply. The equilibrium state of a thermally insulated system corresponds to the maximum of entropy.

► Examples of non-equilibrium processes.

Example 1. Heat exchange. Consider heat exchange between two bodies having initial temperatures T_1 and T_2 and identical heat capacities C. From the heat balance equation it follows that the bodies will reach the same equilibrium temperature $T_\mathrm{f} = \frac{1}{2}(T_1 + T_2)$. Moreover, according to (P2.4.2.3), the entropy change of the system will be positive:

$$\Delta S = C \ln\left(\frac{T_\mathrm{f}}{T_1}\right) + C \ln\left(\frac{T_\mathrm{f}}{T_2}\right) = C \ln\left(\frac{T_\mathrm{f}^2}{T_1 T_2}\right) > 0;$$

the argument of the logarithm is greater than one, since the arithmetic mean is greater than the geometric mean.

Example 2. Expansion of an ideal gas into a vacuum. The internal energy and, hence, temperature of an ideal gas remain constant when it expands into a vacuum. The entropy change can be found from (P2.4.2.4):

$$S_2 - S_1 = \nu R \ln\left(\frac{V_2}{V_1}\right). \tag{P2.4.3.3}$$

Entropy increase in adiabatic expansion into a vacuum (volume increase under constant internal energy) can be proved for any simple system. If S in (P2.4.2.2) is treated as a function of U and V, then $\left(\dfrac{\partial S}{\partial V}\right)_U = \dfrac{p}{T} > 0$.

Example 3. Gas mixing. Consider a thermally insulated container divided by a partition into two equal compartments each containing one mole of an ideal gas under the same temperatures and pressures. When the partition is removed, the gases mix with each other. As follows from (P2.4.3.3), the entropy of the system is increased by $2R\ln 2$ (*entropy of mixing*). If the gases are different, the initial state of the system is different from the final state; the gases can be separated again by doing work on special pistons letting through only one sort of molecules. However, if the gases are identical, the initial and final states of the system are the same, and hence the entropy must not change. The absence of a continuous transition when nearly identical molecules are replaced by completely identical ones is called the *Gibbs paradox*.

P2.4.4. Statistical Meaning of Entropy

Boltzmann's entropy formula relates the entropy S of a macroscopic state of a system to the *statistical weight* W of this macrostate (or the number of microstates corresponding to the given macrostate):

$$S = k \ln W, \tag{P2.4.4.1}$$

where k is the *Boltzmann constant*. The greater W, the higher the probability of the macrostate; in non-equilibrium processes, the systems goes from less probable states to more probable states. The logarithm provides for the additivity of entropy: the statistical weight of a system consisting of two independent subsystems equals the product of their statistical weights. (For more details about the statistical meaning of entropy, see Subsection P7.1.1.

Example. Identity of particles and the Gibbs paradox. To illustrate the application of formula (P2.4.4.1), let us calculate the spatial part of the entropy of an ideal gas. Imagine that the whole volume V of the system is divided into small cells of volume v. The corresponding number of independent states equals $W = (V/v)^N$, where N is the number of molecules in the gas. Then the entropy is $S = k\ln W = kN\ln(V/v) = \nu R\ln(V/v)$. Quantum statistics states that two identical particles are indistinguishable in principle, which means that W must be divided by the number of permutations $N!$. Finally, the spatial part of the entropy becomes $S = kN\ln(V/Nv)$. It can be seen that this approach allows us to resolve the Gibbs paradox.

P2.4.5. Third Law of Thermodynamics

The third law of thermodynamics (also known as *Nernst's theorem*) states that as a system approaches absolute zero, its entropy tends to a certain constant value independent of the values of other thermodynamic parameters. The entropy of a system at $T = 0$ is commonly taken to be zero. From the statistical viewpoint this is explained as follows: at $T = 0$, the system is in its lowest energy state whose statistical weight is very low (close to 1) and, by Boltzmann formula (P2.4.4.1), the entropy is negligibly small. It follows from this law that as $T \to 0$, the heat capacities C_V and C_p of the system as well as its thermal volume expansion and pressure coefficients, α and β, tend to zero.

P2.4.6. Thermodynamic Potentials

► **System in a thermostat.** Consider a change in the state of a system that is in a thermal contact with a thermostat having a constant temperature T. The system will have the same temperature at its initial and final equilibrium states. With $T^{\rm e} = \text{const}$ and after a sequence of transformations

$$Q/T \le S_2 - S_1 \quad \Longrightarrow \quad (U_2 - U_1) + A \le TS_2 - TS_1,$$

inequality (P2.4.3.1) becomes

$$(U_1 - TS_1) - (U_2 - TS_2) \ge A \tag{P2.4.6.1}$$

► **Helmholtz free energy.** With the new state variable

$$F = U - TS, \tag{P2.4.6.2}$$

called the *Helmholtz free energy*, inequality (P2.4.6.1) becomes

$$F_1 - F_2 \ge A.$$

If the volume of the system does not change in a non-equilibrium process, then

$$F_2 \le F_1,$$

and so the free energy does not increase. This fact can be rephrased as follows: an equilibrium state of a system of constant volume that is in thermal contact with a thermostat corresponds to the minimum of the free energy. For an equilibrium process, both inequalities above become equalities.

If a system placed in a thermostat and having constant volume is used to produce some "useful" work (e.g., by connecting internal moving parts of the system with external bodies), then the *maximum work* done by the system as it passes from state 1 to state 2 is equal to

$$A_{\rm max} = F_1 - F_2,$$

with the maximum work being done in a completely reversible equilibrium process. This is why this thermodynamic function is called free energy.

From formulas (P2.4.6.2) and (P2.4.2.2) it follows that

$$dF = -S\,dT - p\,dV. \tag{P2.4.6.3}$$

Therefore, the natural variables to express free energy are volume and temperature: $F = F(V,T)$.

► **Gibbs free energy.** Suppose that a thermodynamic system is placed in a thermostat and is in mechanical contact (e.g., through a light piston or a flexible envelope) with the environment that has a fixed pressure p (the system will have the same pressure in the equilibrium state). Then the work done by the system to change its volume equals $A = p(V_2 - V_1)$. From (P2.4.6.1) we get

$$F_1 + pV_1 \geq F_2 + pV_2 \qquad \text{or} \qquad G_1 \geq G_2, \tag{P2.4.6.4}$$

with

$$G = F + pV = U - TS + pV. \tag{P2.4.6.5}$$

The new thermodynamic function G is called the *Gibbs free energy*. It does not increase in non-equilibrium processes and remains constant in completely reversible equilibrium processes. The minimum of $G(p,T)$ corresponds to an equilibrium state. The maximum “useful” work that the system can perform (i.e., the total work minus the work done to change the volume of the system) equals

$$A_{\max} = G_1 - G_2.$$

Since

$$dG = -S\,dT + V\,dp, \tag{P2.4.6.6}$$

the natural variables for the Gibbs free energy are pressure and temperature: $G = G(p,T)$.

► **Chemical potential.** If the pressure and temperature are kept constant, the Gibbs free energy is proportional to the quantity of substance: $G(p,T,m) = mg$ or $G(p,T,N) = N\mu$, where g is the *specific Gibbs free energy* and μ is the thermodynamic potential per molecule, or the *chemical potential*. (Sometimes, the chemical potential per mole is used.)

► **Canonic equations of state. Natural variables.** Although the functions U, H, F, and G, called *thermodynamic potentials*, can be expressed in terms of any independent variables, there are so-called *natural variables* associated with each of them. These are S and V for internal energy, S and p for enthalpy, V and T for Helmholtz free energy, and p and T for the Gibbs free energy. Below are the definitions and the differentials of the above functions listed together:

$$\begin{aligned} & & dU &= T\,dS - p\,dV + \mu\,dN;\\ H &= U + pV; & dH &= T\,dS + V\,dp + \mu\,dN;\\ F &= U - TS; & dF &= -S\,dT - p\,dV + \mu\,dN;\\ G &= U + pV - TS; & dG &= -S\,dT + V\,dp + \mu\,dN. \end{aligned} \tag{P2.4.6.7}$$

Note that each differential has the additive term $\mu\,dN$, which shows the dependence of each function on the number of particles in the system. The expression of a thermodynamic potential in terms of its natural variables is called a *canonic equation of state*. Given a canonic equation, one can obtain both the thermic, $p = p(V,T)$, and caloric, $U(V,T)$, equations of state. For example, $-\left(\frac{\partial F}{\partial V}\right)_T$ gives the expression for $p(V,T)$ and also, having expressed $S(V,T) = -\left(\frac{\partial F}{\partial T}\right)_V$, one finds $U(V,T) = F + TS$.

► **Maxwell's identities.** By equating the cross derivatives of any thermodynamic function with respect to any two variables, one can obtain useful thermodynamic relations, called

Maxwell's identities. Below are Maxwell's identities for the thermodynamic potentials:

$$\begin{aligned}&\left(\frac{\partial T}{\partial V}\right)_S=-\left(\frac{\partial p}{\partial S}\right)_V;\\&\left(\frac{\partial T}{\partial p}\right)_S=\left(\frac{\partial V}{\partial S}\right)_p;\\&\left(\frac{\partial S}{\partial V}\right)_T=\left(\frac{\partial p}{\partial T}\right)_V;\\&\left(\frac{\partial S}{\partial p}\right)_T=-\left(\frac{\partial V}{\partial T}\right)_p.\end{aligned}\tag{P2.4.6.8}$$

Example 1. With Maxwell's identities, it is quite easy to obtain the formula for $\left(\frac{\partial U}{\partial V}\right)_T$ that was derived in Subsection P2.3.3 using an infinitesimally small Carnot cycle. The first equation in (P2.4.6.7) gives

$$\left(\frac{\partial U}{\partial V}\right)_T=T\left(\frac{\partial S}{\partial V}\right)_T-p.$$

Inserting the third identity in (P2.4.6.8), we arrive at the desired formula.

Example 2. Find the quantity of heat required for 1 kg of mercury to be isothermally compressed from 1 atm to 10 atm. The thermal volume expansion coefficient $\alpha = 1.8\times10^{-4}\,\mathrm{K}^{-1}$ and the mercury density $\rho = 13.55\times10^3\,\mathrm{kg\,m}^{-3}$ are assumed to be unchangeable.

Solution. It follows from the last Maxwell's identity in (P2.4.6.8) that

$$Q=T\Delta S=T\left(\frac{\partial S}{\partial p}\right)_T\Delta p=-T\left(\frac{\partial V}{\partial T}\right)_p\Delta p=-TV\frac{1}{V}\left(\frac{\partial V}{\partial T}\right)_p\Delta p=-\frac{m}{\rho}T\alpha\Delta p=-3.6\,\mathrm{J}.$$

P2.5. Kinetic Theory of Ideal Gases

P2.5.1. The Basic Equation of the Kinetic Theory

► **Pressure of an ideal gas.** From the viewpoint of kinetic-molecular theory, a gas is considered ideal if the potential energy of interaction among its molecules is negligible as compared to the kinetic energy and the molecule size is negligible as compared to the average distance between the molecules. The pressure on the walls of the container results from numerous elastic collisions of the molecules with them. (The collisions can be treated as elastic, on the average, since the gas is in thermal equilibrium with the walls.) The *basic equation of the kinetic theory of an ideal gas* expresses pressure in terms of the mean square velocity of the molecules:

$$p=\tfrac{1}{3}n\langle\mathbf{pv}\rangle=\tfrac{1}{3}nm_0\langle v^2\rangle=\tfrac{2}{3}n\langle\varepsilon_{\text{transl}}\rangle,\tag{P2.5.1.1}$$

where $n=N/V$ is the number of molecules per unit volume, m_0 is the mass of one molecule, $\mathbf{p}=m_0\mathbf{v}$ is its momentum, and $\langle\varepsilon_{\text{transl}}\rangle=\langle\tfrac{1}{2}m_0v^2\rangle$ is the mean kinetic energy of translational motion of a molecule.

If the relation between energy and momentum is other than classical, then the expression in (P2.5.1.1) is different. For example, $|\mathbf{p}|=\varepsilon/c$ for a photon (see Subsection P1.10.3). As a result, pressure is expressed as

$$p=\tfrac{1}{3}n\langle\varepsilon\rangle\tag{P2.5.1.2}$$

for a photon gas.

► **Number of collisions against the wall.** The number of molecules, ΔN, hitting a wall region of area ΔS in time Δt equals

$$\frac{\Delta N}{\Delta S \Delta t} = \frac{n\langle v\rangle}{4}. \tag{P2.5.1.3}$$

Calculation formulas. Formulas for the transfer of the number of molecules, momentum, energy, etc. through a small area are obtained by dividing molecules into groups and calculating the contribution of each group. One of the most common approaches is to group molecules having nearly the same velocity, **v**. Consider the group of molecules having velocity magnitudes in the range from v to $v + dv$ in a solid angle $d\Omega$. The number of molecules in this group per unit volume equals $dn(v,\ v+dv;\ d\Omega) = dn(v,\ v+dv)\,d\Omega/4\pi$. In order to find how many molecules in this group pass through a plane region of area ΔS in time Δt, we should construct an oblique cylinder based on this region (Fig. P2.3) whose generatrix has the length $v\Delta t$ and make an angle θ with the x-axis. The molecules from the group concerned that belong to this cylinder only will reach its base in time Δt. Integrating first with respect to angles ($d\Omega = \sin\theta\, d\theta\, d\varphi$) and then with respect to v, one can obtain formulas (P2.5.1.1), (P2.5.1.3), and others. For example, the energy transferred through area ΔS in time Δt is expressed as

$$\begin{aligned}\Delta E &= \int \frac{m_0 v^2}{2}\, dn(v, v+dv)\, \frac{d\Omega}{4\pi}\, \big(\Delta S\, v\Delta t \cos\theta\big)\\ &= \frac{m_0 n}{8} \Delta S\, \Delta t \int_0^\infty \frac{v^3\, dn(v, v+dv)}{n} = \frac{m_0 n\langle v^3\rangle}{8} \Delta S\, \Delta t.\end{aligned} \tag{P2.5.1.4}$$

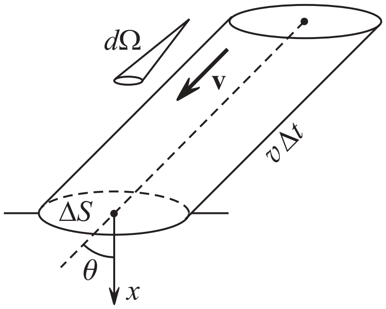

Figure P2.3. To the calculation of the number of molecules passing through a region of area ΔS in time Δt.

P2.5.2. Temperature and Energy of an Ideal Gas

► **Temperature definition in kinetic theory of gases.** It is proved in kinetic theory of gases that if two subsystems (consisting of identical or different molecules) can exchange energy, their mean kinetic energies of translational motion per molecule are equal to each other in equilibrium. Based on this fact, kinetic theory of gases defines temperature as a quantity proportional to the average kinetic energy of translational motion of molecules:

$$\langle \varepsilon_{\text{transl}}\rangle = \frac{3}{2}kT, \tag{P2.5.2.1}$$

where k is the *Boltzmann constant*. The proportionality coefficient is chosen so that the equation of state of an ideal gas,

$$p = nkT = \frac{N}{V}kT, \tag{P2.5.2.2}$$

obtained from the basic equation (P2.5.1.1) and the temperature definition (P2.5.2.1), coincides with equation (P2.1.2.1), where the gas temperature scale is used.

► **Root mean square velocity.** Using (P2.5.1.1) and (P2.5.2.1), one can calculate the root mean square velocity of translational motion of molecules:

$$v_{\rm rms} = \sqrt{\langle v^2\rangle} = \sqrt{\frac{3p}{\rho}} = \sqrt{\frac{3kT}{m_0}} = \sqrt{\frac{3RT}{\mu}}, \qquad \text{(P2.5.2.3)}$$

where $\rho = m_0 n$ is the gas density.

► **Internal energy of an ideal gas.** The *number of degrees of freedom* of a molecule, i, is an important characteristic of an ideal gas. A monatomic molecule has only three degrees of freedom; these correspond to translational motion in three spatial coordinates: $i = i_{\rm transl} = 3$. A rigid diatomic molecule has two additional, rotational degrees of freedom, associated with the rotation about two axes perpendicular to the axis of the molecule: $i = i_{\rm transl} + i_{\rm rot} = 3+2 = 5$. A rigid multiatomic molecule (whose atoms are not collinear) has three rotational degrees of freedom, and therefore $i = 6$. Classical statistical physics proves the *equipartition theorem* (also known as *law of equipartition*). According to this theorem, an average energy of $\frac{1}{2}kT$ per molecule is associated with any degree of freedom to which there corresponds a term like αx^2 or $\beta\dot{x}^2$ in the expression of the molecule energy. Formula (P2.5.2.1) is in complete agreement with this theorem. Accordingly, the average energy per one molecule and the total internal energy of the gas are expressed as

$$\langle\varepsilon\rangle = \tfrac{1}{2} i_{\rm phys} kT, \qquad U = N\langle\varepsilon\rangle = \tfrac{1}{2} i_{\rm phys}\nu RT. \qquad \text{(P2.5.2.4)}$$

The physical number of degrees of freedom, $i_{\rm phys}$, for rigid molecules coincides with the mathematical one. However, at sufficiently high temperatures ($T \sim 10^3$ K), when molecules can no longer be treated as rigid and vibrational energy must be taken into account, an average energy of kT will be associated with each vibrational degree of freedom. As a result, the total number of degrees of freedom becomes $i_{\rm phys} = i_{\rm transl} + i_{\rm rot} + 2i_{\rm vib}$, where $i_{\rm vib}$ is the mathematical number of vibrational degrees of freedom in a molecule. For an s-atom molecule, $i_{\rm vib} = 3s - (i_{\rm transl} + i_{\rm rot})$. In particular, for a nonrigid diatomic molecule, we have $i_{\rm vib} = 6 - (3+2) = 1$ and $i_{\rm phys} = 3 + 2 + 2\times 1 = 7$.

► **Heat capacities of an ideal gas.** Using (P2.5.2.4) and the definitions of heat capacities at constant volume and constant pressure as well as adiabatic index (see Subsection P2.2.3), we find that

$$C_V^{\rm m} = \frac{i_{\rm phys}}{2}RT, \qquad C_p^{\rm m} = \frac{i_{\rm phys}+2}{2}RT, \qquad \gamma = \frac{C_p}{C_V} = \frac{i_{\rm phys}+2}{i_{\rm phys}}. \qquad \text{(P2.5.2.5)}$$

At room temperatures, the heat capacity follows the model of rigid molecules; the rotational degrees of freedom are not excited, or, as is often said, “frozen.” However, at temperature increases to $\sim 10^3$ K, the heat capacity begins to increase, that is, vibrational degrees of freedom “unfreeze.” Furthermore, as temperature decreases to several tens of kelvins, the rotational degrees of freedom “freeze out,” which results in decreasing heat capacity. The phenomenon of *freezing-out of degrees of freedom* is explained by quantum mechanics: if the average energy of thermal motion, kT, is small compared to the distance to the nearest discrete energy level, the kind of motion concerned is not excited.

► **Mixture of ideal gases.** *Dalton’s law* reads: the pressure of a mixture of ideal gases equals the sum of their partial pressures. In particular, for two gases,

$$p = p_1 + p_2 = (n_1 + n_2)kT = (\nu_1 + \nu_2)RT.$$

The internal energy of a mixture equals the sum of the internal energies of its components: $U = \frac{1}{2}i_1\nu_1 RT + \frac{1}{2}i_2\nu_2 RT$. This formula allows us to introduce the so-called effective number of degrees of freedom, $i(\nu_1+\nu_2) = i_1\nu_1 + i_2\nu_2$, effective molar heat capacity, $(\nu_1+\nu_2)C_\mu = \nu_1 C_{\mu 1} + \nu_2 C_{\mu 2}$, and effective molar mass, $(\nu_1+\nu_2)\mu = \nu_1\mu_1 + \nu_2\mu_2$.

P2.5.3. Maxwell's Distribution

► **Definition and properties of distribution functions.** The distribution of molecules over their velocities is characterized by the following functions:

$$\begin{aligned}\varphi(v_x)\,dv_x &= \frac{dn(v_x,\,v_x+dv_x)}{n},\\ f(v)\,dv &= \frac{dn(v,\,v+dv)}{n},\\ \Phi(\mathbf{v})\,dv_x\,dv_y\,dv_z &= \frac{dn(v_x,\,v_x+dv_x;\;v_y,\,v_y+dv_y;\;v_z,\,v_z+dv_z)}{n}.\end{aligned}\qquad\text{(P2.5.3.1)}$$

The definition of each of the distribution functions is based on the assumption that the fraction of molecules that fall (on the average) within a very small interval of a given variable (e.g., velocity, its projection onto an axis, energy, etc.) is proportional to the width of this interval. Note that dv denotes a physically very narrow, rather than mathematically infinitesimal, interval but wide enough to contain a large number of molecules. The mean fraction of molecules having a certain property (e.g., having velocities within a given interval) can be treated as the probability that an arbitrary molecule possesses this property. Therefore, a distribution function is sometimes referred to as a *probability density function*.

Listed below are properties of a distribution function (exemplified by $f(v)$).

1. The fraction of particles (probability) having velocities within a finite interval (v_1, v_2):

$$\frac{\Delta n(v_1,v_2)}{n} = \int_{v_1}^{v_2} f(v)\,dv.$$

2. Normality:

$$\int_0^\infty f(v)\,dv = 1.\qquad\text{(P2.5.3.2)}$$

3. Computation of the average of any function $\chi(v)$:

$$\langle\chi(v)\rangle = \int_0^\infty \chi(v)\,f(v)\,dv.\qquad\text{(P2.5.3.3)}$$

The three distribution functions defined in (P2.5.3.1) are related by

$$f(v) = \Phi(v)4\pi v^2,\qquad \Phi(v_x,v_y,v_z) = \varphi(v_x)\varphi(v_y)\varphi(v_z).$$

The function φ is even, and hence one can write $\varphi = \varphi(v_x^2)$. The function $\Phi(\mathbf{v})$ depends on $v^2 = v_x^2+v_y^2+v_z^2$ only. The relation between Φ and φ is satisfied only if $\varphi(v_x) = A\exp(-\zeta v_x^2)$. The coefficients A and ζ are determined from two conditions: (a) the normality of φ and (b) the requirement that $\langle v_x^2\rangle = \frac{1}{3}\langle v^2\rangle = kT/m_0$; see (P2.5.2.3). Thorough calculations give the answer

$$\begin{aligned}\varphi(v_x) &= \Bigl(\frac{m_0}{2\pi kT}\Bigr)^{1/2}\exp\Bigl(-\frac{m_0v_x^2}{2kT}\Bigr),\\ f(v) &= \Bigl(\frac{m_0}{2\pi kT}\Bigr)^{3/2}\exp\Bigl(-\frac{m_0v^2}{2kT}\Bigr)4\pi v^2.\end{aligned}\qquad\text{(P2.5.3.4)}$$

The latter expression is referred to as *Maxwell's distribution* (Fig. P2.4). The function $f(v)$ attains its maximum at $v_{\rm mp} = (2kT/m_0)^{1/2}$, which is called the *most probable velocity*. The value of $f(v)$ at this point is $f(v_{\rm mp}) = 4e^{-1}(2\pi kT/m_0)^{-1/2}$. For example, it

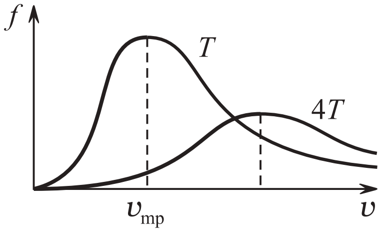

Figure P2.4. Maxwell's distribution function.

follows that if T increases by a factor of 4, the most probable velocity doubles and the value of the function, $f(v_{\rm mp})$, is halved; note that the area under the curve $f(v)$ is equal to one.

The *average velocity* (arithmetic mean) of molecules is calculated by (P2.5.3.3):

$$\langle v\rangle = \int_0^\infty v f(v)\,dv = \sqrt{\frac{8kT}{\pi m_0}} = \sqrt{\frac{8RT}{\pi\mu}}.$$

The distribution of molecules over the energies of their translational motion is determined by

$$\psi(\varepsilon)\,d\varepsilon = \frac{dn(\varepsilon,\,\varepsilon+d\varepsilon)}{n} = \frac{2}{\sqrt{\pi}}\exp\Bigl(-\frac{\varepsilon}{kT}\Bigr)\sqrt{\frac{\varepsilon}{kT}}\,d\Bigl(\frac{\varepsilon}{kT}\Bigr).$$

Useful integrals. In calculating averages using Maxwell's distribution, the following integrals often arise: $I_n = \int_0^\infty x^n \exp(-\beta x^2)\,dx$ $(n = 0, 1, 2, \dots)$. The first two integrals are $I_0 = \frac{1}{2}\sqrt{\pi}\,\beta^{-1/2}$ and $I_1 = \frac{1}{2}\beta^{-1}$. Other integrals can be calculated by differentiating I_0 or I_1 with respect to β. For example, $I_2 = -\dfrac{dI_0}{d\beta} = \frac{1}{4}\sqrt{\pi}\,\beta^{-3/2}$.

P2.5.4. Boltzmann's Distribution

► **Boltzmann's distribution.** If a gas is in an external force field, the concentration of molecules depends on the spatial position. It can be obtained from the condition of mechanical equilibrium of the gas that

$$n(\mathbf{r}) = n(\mathbf{r}_0)\exp\left[-\frac{\varepsilon_{\rm p}(\mathbf{r}) - \varepsilon_{\rm p}(\mathbf{r}_0)}{kT}\right], \qquad \text{(P2.5.4.1)}$$

where $\varepsilon_{\rm p}(\mathbf{r})$ is the potential energy of a molecule in the external field. Formula (P2.5.4.1) is known as *Boltzmann's distribution*. The barometric formula

$$p(h) = n(h)kT = p_0\exp\Bigl(-\frac{m_0gh}{kT}\Bigr), \quad \text{where} \quad n(h) = n_0\exp\Bigl(-\frac{m_0gh}{kT}\Bigr), \qquad \text{(P2.5.4.2)}$$

is a special case of Boltzmann's distribution.

Let us illustrate the derivation of Boltzmann's distribution using the barometric formula as an example. The equilibrium condition for a vertical cylinder with the base area s and height dh in the field of gravity is: $s\,dp = -\rho(s\,dh)g$. Then, using the equations $p = nkT$ and $\rho = m_0n$, we obtain $\dfrac{dn}{dh} = -\dfrac{m_0g}{kT}n$. Integrating yields the barometric formula.

► **Maxwell–Boltzmann distribution.** Both Maxwell's and Boltzmann's distributions, (P2.5.3.4) and (P2.5.4.1), contain the expression $\exp(-\varepsilon/kT)$. The combined Maxwell–Boltzmann distribution expresses the probability that an arbitrary molecule from a container with N molecules is in the spatial region $(x,\ x+dx;\ y,\ y+dy;\ z,\ z+dz)$ and has the velocity within $(v_x,\ v_x+dv_x;\ v_y,\ v_y+dv_y;\ v_z,\ v_z+dv_z)$:

$$\frac{dN}{N}=\frac{dn(\mathbf{r})\,d^3\mathbf{r}}{N}=\frac{n(\mathbf{r})\Phi(\mathbf{v})}{N}\,d^3\mathbf{r}\,d^3\mathbf{v}=A\exp\Bigl(-\frac{\varepsilon}{kT}\Bigr)d^3\mathbf{r}\,d^3\mathbf{v},\qquad\text{(P2.5.4.3)}$$

where $d^3\mathbf{r}=dx\,dy\,dz$, $d^3\mathbf{v}=dv_x\,dv_y\,dv_z$, $\varepsilon=\frac{1}{2}m_0v^2+\varepsilon_\text{p}(\mathbf{r})$ is the mechanical energy of a molecule, A is a coefficient that can be found from the normality condition. The Maxwell–Boltzmann distribution applies to any kinds of molecule energy: rotational, vibrational, potential, angular orientation dependent, and others.

P2.6. Real Gases. Van Der Waals Equation

P2.6.1. Isotherms of a Real Gas

► **Low temperatures, $T<T_\text{c}$.** If the gas temperature is less than the critical temperature (see below), then the following processes occur in equilibrium isothermal volume contraction (Fig. P2.5):

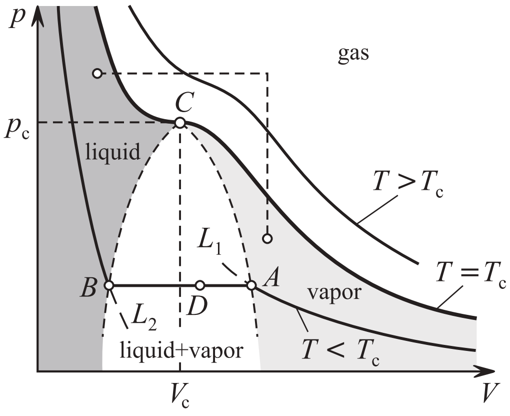

Figure P2.5. Isotherms of a real gas. ACB is the region of two-phase equilibrium.

1. Pressure increases to the point A. If temperature is well below the critical temperature, then the ideal gas law works well up to the point A.

2. Pressure does not change along AB. Some liquid emerges in the container; it is separated from the gas by a clear interphase surface. A gas which is in thermodynamic equilibrium with its liquid phase is called a *saturated vapor*. The liquid-to-gas mass ratio at a point D on the segment AB equals the ratio between the lengths of the segments AD and DB: $m_\text{liq}/m_\text{vap}=AD/DB$. The isotherm portions AL_1 and L_2B correspond to *metastable states*, or states at which the system can remain for some time but then quickly passes to a stable state on the segment AB. A gas and liquid in a metastable state are called a *supercooled vapor* and *superheated liquid* (at constant pressure). The existence of metastable states is accounted for by the fact that the formation of tiny nuclei of a new phase (liquid in vapor or vapor in liquid) requires a considerable amount of energy, known as surface energy (see Subsection P2.8.1).

3. After the point B, pressure sharply increases. There is only the liquid phase in the container.

► **Critical temperature, $T = T_c$.** The higher the temperature, the shorter the horizontal portion of the isotherm. At some *critical temperature*, T_c, it reduces to a mere point, C, the inflection point of the isotherm (Fig. P2.5). The pressure at the *critical point* is called the *critical pressure*, p_c, and the volume of a single mole of the gas is called the *critical molar volume*, V_c.

► **High temperatures, $T > T_c$.** For higher temperatures, $T > T_c$, the isotherm is a smooth monotonic curve. The region above the critical isotherm is called the true gas (it cannot be isothermally transferred to a liquid + vapor state). The region below the critical isotherm consists of three subregions: liquid, unsaturated vapor, and liquid + saturated vapor. It is possible to pass (non-isothermally) from the vapor region to the liquid region without entering the liquid + vapor region. So gas and liquid differ from each other by only quantitative characteristics.

The critical parameters of some substances are shown in the table below.

TABLE P2.1
Critical parameters of some substances.

Substance	T_c, K	p_c, MPa	V_c, cm^3/mol
Helium, He	5.19	0.277	57.4
Hydrogen, H_2	33.24	1.30	65.0
Neon, Ne	44.4	2.654	41.7
Nitrogen, N_2	126.3	3.40	90.1
Oxygen, O_2	154.6	5.04	78
Methane, CH_4	190.66	4.626	99.38
Krypton, Kr	209.39	5.49	91.9
Carbon dioxide, CO_2	304.1	7.38	94.0
Hydrogen sulphide, H_2S	373.6	9.01	97.4
Water, H_2O	647.3	22.12	56
Mercury, Hg	1460	166.1	48
Lithium, Li	3200	68.9	66

P2.6.2. Van Der Waals Equation

► **Van der Waals equation.** The equation of state for one mole of a van der Waals gas is

$$(V_\mu - b)\left(p + \frac{a}{V_\mu^2}\right) = RT. \qquad \text{(P2.6.2.1)}$$

Note that equation (P2.1.2.2) from Section P2.1 for ν moles is obtained by substituting $V_\mu = V/\nu$. The positive constant b reflects the fact that not all of the container volume is available for the motion of molecules due to their own volume. This constant is taken to be the total volume of all molecules multiplied by four: $b = 4N_A \times \frac{1}{6}\pi d^3$, where d is the diameter of a molecule. The term a/V_μ^2 reflects the fact that the total pressure decreases due to mutual interaction of molecules. This can be clearly seen from the expression of the internal energy of a van der Waals gas: $U = C_{\mu V}T - a/V_\mu$.

The average potential energy of interaction among the molecules is characterized by a model expression containing two terms, first corresponding to strong repulsion at small distances ($\sim$ 10^{-10} m) and second corresponding to van der Waals attractive forces at large distances (Fig. P2.6):

$$E_{\rm p} = \frac{\alpha}{r^{12}} - \frac{\beta}{r^6}.$$

The minimum of $E_{\rm p}$ corresponds to the average inter-molecule distance in the absence of thermal motion. For $kT \ll E_{\rm min}$, the motion of molecules reduces to vibrations about the bottom of the potential well (solid state). The case $kT \sim E_{\rm min}$ corresponds to liquid state and the case $kT \gg E_{\rm min}$ corresponds to gaseous state. Since the left branch of the potential curve, corresponding to repulsion, is nearly vertical, the minimum distance to which molecules approach each other before rebounding is weakly dependent on their average translational energy (see also Subsection P1.5.4).

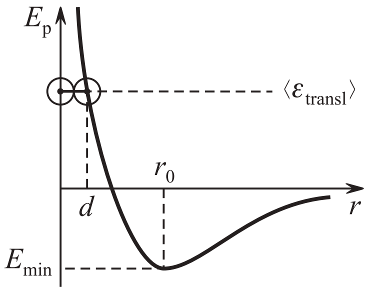

Figure P2.6. Potential energy of interaction of molecules.

► **Van der Waals isotherms.** Figure P2.7 depicts isotherms predicted by the van der Waals equation (P2.6.2.1). At temperatures below the critical value, the isotherms have two extrema, K_1 and K_2. However, for the path AK_1K_2B of a subcritical isotherm, the condition of mechanical stability, $(\partial p/\partial V)_T \le 0$, is violated. In fact, the transition between the points A and B occurs along a horizontal line. According to *Maxwell's rule*, the position of the segment AB is determined by the condition that shaded areas must be equal. Otherwise, the isothermal cycle AK_1K_2BA would perform work, which contradicts the second law of thermodynamics. The portions AK_1 and K_2B correspond to metastable states.

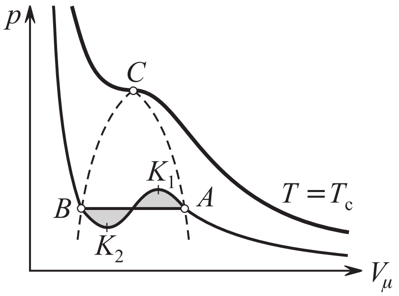

Figure P2.7. Van der Waals isotherms.

► **Calculation of critical parameters.** At the critical point, the following two conditions hold:

$$\left(\frac{\partial p}{\partial V}\right)_T = 0, \qquad \frac{\partial^2 p}{\partial V^2} = 0. \tag{P2.6.2.2}$$

Expressing p from (P2.6.2.1) and substituting into these equations, we find that

$$V_{\rm c} = 3b, \quad p_{\rm c} = \frac{1}{27}\frac{a}{b^2}, \quad T_{\rm c} = \frac{8}{27}\frac{a}{bR}.$$

The critical parameters satisfy the relation $p_c V_c = \frac{3}{8} R T_c$. By introducing the reduced state variables $v = V/V_c$, $\pi = p/p_c$, and $\theta = T/T_c$, one can rewrite the van der Waals equation (P2.6.2.1) as

$$\left(v - \frac{1}{3}\right)\left(\pi + \frac{3}{v^2}\right) = \frac{8}{3}\theta.$$

This equation is the same for all gases. It follows that the van der Waals equation satisfies the experimentally established *principle of corresponding states*. This principle asserts that if two respective reduced state variables for two gases coincide, the third will also coincide. This law is obeyed very well by most real gases.

P2.7. Phase Equilibrium. Phase Transitions

P2.7.1. Conditions for Phase Equilibrium

► **Phase.** A *phase* is a part of a system which is homogeneous in its physical and chemical properties. The same substance can be in different phases, although its chemical composition does not change. Examples of a *two-phase system* are: liquid + saturated vapor, solid + liquid, and solid + vapor.

► **Three equilibrium conditions.** For the phases of a system to be in equilibrium, the following conditions must hold: (1) the pressures must be equal (mechanical equilibrium), (2) the temperatures must be equal (thermal equilibrium), and (3) the chemical potentials must be equal (equilibrium with respect to interphase transitions). The last condition corresponds to the minimum of the Gibbs free energy $G = \mu_1 N_1 + \mu_2 (N - N_1)$ (see Subsection P2.4.6) with respect to the number of molecules in one of the phases, N_1. For a simple system, the condition $\mu_1(p,T) = \mu_2(p,T)$ determines the equation of the *two-phase coexistence curve* $p(T)$; a simple two-phase system has only one degree of freedom. In particular, the pressure of a saturated vapor, determined by the horizontal portion of the isotherm (see Subsection P2.6.1), is a single-valued function of temperature (the *evaporation–condensation curve*). The same applies to the dependence of the melting temperature on the external pressure (the *melting–freezing curve*) and also to the temperature dependence of the vapor pressure over a solid surface (the *sublimation–deposition curve*).

► **Triple point.** Figure P2.7 depicts a schematic phase diagram for water, which includes the three phase-equilibrium curves: evaporation–condensation (I), melting–freezing (II), and sublimation–deposition (III). The point of intersection of the three curves is called the *triple point* (for water, $T_3 = 0.01°\text{C}$ and $p_3 = 610.5$ Pa). The conditions $\mu_{\text{vap}}(p,T) = \mu_{\text{liq}}(p,T)$ and $\mu_{\text{liq}}(p,T) = \mu_{\text{sol}}(p,T)$ must hold simultaneously for a *three-phase system* to exist. The pressure and temperature, identifying the triple point, are determined uniquely by these conditions.

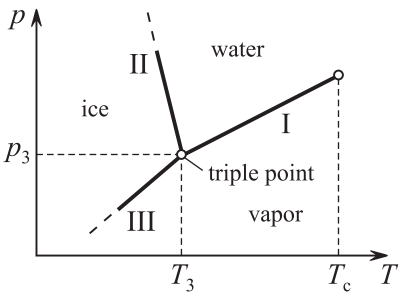

Figure P2.7. Phase diagram for water.

P2.7.2. First-Order Phase Transitions

► **Transition heat and entropy.** In order to transfer a portion of substance of mass m in a two-phase system from one phase to the other, the quantity of heat $Q = mq$ must be supplied (or removed) in an equilibrium isobar-isothermal process. This quantity of heat Q is called the *phase transition heat* or *latent heat*; the quantity q is the *specific phase transition heat* or *specific latent heat*. When a substance changes to a new phase, its entropy changes by $\Delta S = Q/T = mq/T$ and the internal energy, by $\Delta U = mq - mp\Delta v$, where $v = V/m$ is the *specific volume*. The quantity $\Delta s = q/T$ is called the specific entropy of the phase transition, and $\Delta u = q - p\Delta v$ is the change in the specific internal energy at the phase transition.

A transition between phases in a two-phase system in which some heat is absorbed or released and an abrupt change in internal energy, entropy, density, volume, etc. occurs is called a *first-order phase transition*. This name is due to the fact that the first derivatives of the Gibbs free energy, $S = -(\partial G/\partial T)_p$ and $V = (\partial G/\partial p)_T$, experience a jump discontinuity.

► **Clausius–Clapeyron relation.** If the temperature of a two-phase system is changed, then its pressure will adapt so that the chemical potentials (or the specific Gibbs free energies) of the phases remain the same: $dg_1 = dg_2$, or $-s_1\,dT + v_1\,dp = -s_2\,dT + v_2\,dp$ (see Subsection P2.4.6). It follows that the slope of the phase equilibrium curve equals

$$\frac{dp}{dT} = \frac{\Delta s}{\Delta v} = \frac{q}{T\Delta v}. \qquad \text{(P2.7.2.1)}$$

This equation is referred to as the *Clausius–Clapeyron relation*.

Example 1. For the ice–water phase transition at atmospheric pressure, the melting temperature is 273 K, $q = 3.34 \times 10^5$ J/kg, and $v_\mathrm{w} - v_\mathrm{i} = -0.91 \times 10^{-4}$ m^3/kg. Consequently $dp/dT = -1.1 \times 10^7$ Pa/K. The minus sign reflects the anomalous property of water: its density increases in melting.

Example 2. If heat is continuously supplied to a liquid, intensive evaporation begins across the whole volume when the temperature attains the value at which the saturation vapor pressure equals the external pressure. This process is called *boiling*. Equation (P2.7.2.1) determines the dependence between the *boiling temperature* and external pressure. Neglecting the specific volume of the liquid and expressing the specific volume of the vapor from the ideal gas law $v = \dfrac{RT}{\mu p}$, we arrive at the approximate equation $\dfrac{dp}{dT} = \dfrac{\mu q p}{RT^2}$. In particular, for water ($\mu = 18$ g/mol) at atmospheric pressure ($p = 10^5$ Pa), we have the boiling temperature $T = 373$ K and the specific latent heat of evaporation $q = 2.26 \times 10^6$ J/kg. If follows that $\dfrac{dp}{dT} = 3.5 \times 10^3$ Pa/K.

► **Second-order phase transitions.** In a second-order phase transition, density, internal energy, and entropy (the first derivatives of the Gibbs free energy) are changed continuously, while the various derivatives of these thermodynamic functions (such as heat capacity, compressibility, dielectric constant, magnetic permeability, etc.) experience a jump discontinuity or show critical behavior (tend to infinity when approaching the transition point). The name is due to the fact that the second derivatives of the Gibbs free energy experience a discontinuity. Examples of such transitions are the paramagnetic-to-ferromagnetic transition at the Curie point, transition of liquid helium to the superconducting state, superfluid transitions, etc. A second-order phase transition occurs at the whole volume at once and is associated with a qualitative change in the internal structure (such as appearance of additional symmetries or loss of some symmetries).

P2.8. Surface Tension

P2.8.1. Surface Energy

► **Surface tension coefficient**. Molecules at the surface of a liquid possess higher potential energy as compared to molecules in the bulk, since the former have fewer "neighbors," the energy of interaction with which is negative (see Fig. P2.6). At constant temperature, the additional energy is proportional to the surface area, Σ:

$$F_{\text{surf}} = \sigma(T)\Sigma, \tag{P2.8.1.1}$$

where σ is the surface free energy per unit area, called the *surface tension coefficient*.

In an equilibrium isothermal change of a rectangular area on the surface, the work done by external forces equals the change in the Helmholtz free energy (P2.4.6.2). So $A = \Delta F_{\text{surf}} = \sigma\Delta\Sigma = \sigma Lx$, where L is the rectangle side and x is its displacement. It follows that a *surface tension force* acts on the rectangle side which is perpendicular to the side and tangent to the liquid surface:

$$f_{\text{surf}} = \sigma L. \tag{P2.8.1.2}$$

In equilibrium, the Helmholtz free energy is minimum and, hence, a liquid of a liquid film tend to minimize their surface. For example, a drop of liquid tends to a spherical shape at zero gravity.

► **Thermodynamics of surface layer.** Since F_{surf} is a function of T and Σ, then $dF_{\text{surf}} = \sigma\,d\Sigma + \Sigma\dfrac{d\sigma}{dT}\,dT$. It follows, taking into account (P2.4.6.3), that the surface layer entropy and internal energy as well as the heat absorbed by the layer under isothermal area extension are expressed as

$$S = -\frac{d\sigma}{dT}\Sigma, \quad U = F + TS = \left(\sigma - T\frac{d\sigma}{dT}\right)\Sigma, \quad \delta Q = T\,dS = -T\frac{d\sigma}{dT}\,d\Sigma.$$

With increasing temperature T, the surface tension coefficient σ decreases and vanishes at a critical temperature.

P2.8.2. Additional Pressure Under a Curved Surface

► **Spherical surface.** It follows from the condition of mechanical equilibrium of the surface layer that the pressure inside a convex surface must be higher than outside. For a spherical surface of radius R, the additional pressure, Δp, can be found by increasing its radius by dR and equating the work done by external forces with the change in the Helmholtz energy: $\Delta p\,dV = \sigma\,d\Sigma$ and hence $\Delta p\,d(\frac{4}{3}\pi R^3) = \sigma\,d(4\pi R^2)$. Finally, we have

$$\Delta p = \frac{2\sigma}{R}. \tag{P2.8.2.1}$$

► **Young–Laplace formula.** The above equation can be generalized to include two different radii of curvature:

$$\Delta p = \sigma\left(\frac{1}{R_1} + \frac{1}{R_2}\right), \tag{P2.8.2.2}$$

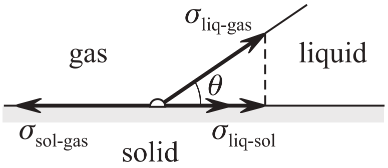
where R_1 and R_2 are the principal radii of curvature of the surface (i.e., the minimum and maximum radii of curvature of the curves obtained by cutting the surface with two mutually perpendicular planes at a given point). Relation (P2.8.2.1) is called the *Young–Laplace formula* or *Young–Laplace equation*.

P2.8.3. Wetting. Capillary Effects

► **Contact angle.** When a liquid and solid are in contact with each other and both are in a gas environment, the liquid surface (liquid–gas interface) and the solid surface (solid–gas interface) meet at an angle, which is called the *contact angle*. The value of the contact angle, θ, depends on the surface tension coefficients at the liquid–gas ($\sigma_{\text{liq–gas}}$), liquid–solid ($\sigma_{\text{liq–sol}}$), and solid–gas ($\sigma_{\text{sol–gas}}$) interfaces. It follows from the condition of mechanical equilibrium at the line where the three phases meet (see Fig. P2.8) that $\sigma_{\text{sol–gas}} = \sigma_{\text{liq–sol}} + \sigma_{\text{liq–gas}} \cos\theta$ (per unit length). Hence,

$$\cos\theta = \frac{\sigma_{\text{sol–gas}} - \sigma_{\text{liq–sol}}}{\sigma_{\text{liq–gas}}}.$$

If $0 < \cos\theta < 1$, or $0 < \theta < 90^\circ$, the liquid is said to *wet* the solid surface. If $-1 < \cos\theta \le 0$, or $90^\circ \le \theta < 180^\circ$, it is said that the liquid does not wet the surface. If the right-hand side of the equation is greater than or equal to 1 ($\theta = 0$), the liquid forms a thin molecular film of the solid surface (this phenomenon is known as *perfect wetting*); in a container, the liquid makes a zero angle with the solid wall. If the right-hand side of the equation is less than or equal to –1 ($\theta = 180^\circ$), this situation is known as *perfect non-wetting*.



$\sigma_{\text{liq-gas}}$
gas
liquid
θ
$\sigma_{\text{sol-gas}}$
solid
$\sigma_{\text{liq-sol}}$

Figure P2.8. Contact angle.

► **Capillary effects.** If one end of a thin, capillary tube is immersed in a wetting liquid, the liquid will go up the capillary and reach a height h. This height is determined by the mechanical equilibrium condition.

If there is a capillary tube with inner radius r and the radius of curvature of the liquid meniscus is $R = r/\cos\theta$, the pressure under the meniscus (see (P2.8.2.1)) must be less than atmospheric pressure by the value $2\sigma/R = 2\sigma\cos\theta/r$. Equating the pressure difference with ρgh, we find the height of the liquid column: $h = \dfrac{2\sigma\cos\theta}{\rho gr}$.

P2.9. Transfer Phenomena in Gases

P2.9.1. Collision of Molecules in a Gas

► **Collision frequency.** For a given molecule in a gas, its average number of collisions per unit time (collision frequency) with other molecules is equal to

$$z = n\sigma\langle v\rangle\sqrt{2}, \tag{P2.9.1.1}$$

where n is the molecule concentration, $\langle v\rangle$ is the average speed of the molecules, and σ is the *effective cross-section* of elastic collisions. If the molecules are modeled as identical rigid balls of diameter d, we have $\sigma = \pi d^2$. The factor $\sqrt{2}$ accounts for the motion of oncoming molecules; this factor is usually omitted in the qualitative theory of transfer phenomena.

In order to estimate the collision frequency, the polygonal path of a molecule is usually surrounded by a tube of radius d. The moving molecule will collide with any resting molecule whose center is inside the tube. In a unit time, the molecule travels the distance $\langle v\rangle$, the corresponding tube volume equals $\pi d^2\langle v\rangle$, and the number of molecules in the tube is $z = \pi d^2\langle v\rangle n$.

► **Mean free path.** The average distance traveled by a molecule between successive collisions, the *mean free path*, is equal to

$$\lambda = \frac{\langle v\rangle}{z} = \frac{1}{n\sigma\sqrt{2}}. \tag{P2.9.1.2}$$

The total number of collisions among molecules in a unit volume per unit time is

$$\nu = \frac{zn}{2} = \frac{n\langle v\rangle}{2\lambda} = \frac{n^2\sigma\langle v\rangle\sqrt{2}}{2}. \tag{P2.9.1.3}$$

Effective cross-section. The effective cross-section of an interparticle collision process (with respect to a result of interest, such as scattering within a given solid angle, particle absorption, etc.) is determined as follows. Consider a fixed molecule (a scattering center) and an incident beam of molecules with flux $I = nv$ (the number of particles passing through a unit area per unit time, with the area perpendicular to the velocity vector). The effective cross-section of a process is the ratio between the number of collisions per unit time that have led to the desired result, ΔN, and the incident flux:

$$\sigma = \Delta N/I. \tag{P2.9.1.4}$$

The attenuation of the molecule beam traveling through a gas over a distance dx equals

$$dI = -I\sigma n\,dx = -(I/\lambda)\,dx,$$

where σ is the cross-section of elastic scattering, $n\,dx$ is the number of scattering centers along the path dx (per unit area), and $\lambda = 1/(n\sigma)$. Integrating yields the incident flux as a function of the distance traveled:

$$I = I_0\exp(-n\sigma x) = I_0\exp(-x/\lambda). \tag{P2.9.1.5}$$

It follows that the probability for a molecule to experience a collision on the interval $(x,\, x + dx)$ is $|dI|/I_0 = \exp(-x/\lambda)\,d(x/\lambda)$. The mean distance traveled by a molecule to the first collision equals

$$\langle x\rangle = \int_0^\infty x\exp\Bigl(-\frac{x}{\lambda}\Bigr)\frac{dx}{\lambda} = \lambda.$$

P2.9.2. Qualitative Model of Transfer Phenomena in Gases

The phenomena of viscosity, heat conduction, and diffusion are accounted for by the transfer of linear momentum, energy, and concentration due to chaotic thermal motion.

► **Viscosity. Fourier's law.** Viscosity is the appearance of frictional forces between parallel gas layers as they move relative to each other. If the directed flow velocity, $\mathbf{u}$, is parallel to the x-axis and only changes in the y-direction (Fig. P2.9), then a resistive force arises which is proportional to the area and the velocity gradient:

$$|F_x| = \eta S\frac{du}{dy}, \tag{P2.9.2.1}$$

where η is the *coefficient of viscosity* (or simply the *viscosity*). Equation (P2.9.2.1) is known as *Fourier's law*. The appearance of the resistive force is associated with the transfer of the momentum p_x along the y-axis by the molecules crossing the contact area due to their thermal motion. The force per unit area equals the momentum flux density.

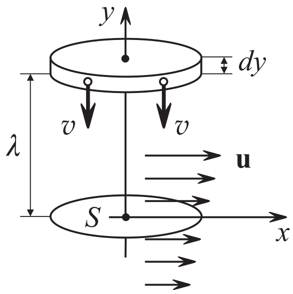


Figure P2.9. A frictional force arises between adjacent gas layers having different relative velocities.

► **Heat conduction. Newton's law of cooling.** If the gas temperature rather than the directed flow velocity changes along the y-axis, then the local heat flux density in the y-direction is expressed as

$$q = -\kappa \frac{dT}{dy}, \tag{P2.9.2.2}$$

where κ is the *thermal conductivity*. This equation is known as Newton's law of cooling.

► **Diffusion. Fick's law.** If the concentration of selected gas molecules, n_1, changes along the y-axis (the total concentration n must be constant), then the flux density of the selected molecules, j, in the y-direction is given by

$$j = -D \frac{dn_1}{dy}, \tag{P2.9.2.3}$$

where D is the *diffusion coefficient* (or *diffusivity*). This equation is known as *Fick's law of diffusion*. The quantity j is called the *diffusion flux density*.

► **Flux calculation formulas.** Let $g(y)$ denote a quantity whose transfer along the y-axis is of interest. Examples of such a quantity are the momentum of directed motion, $g(y) = m_0 u(y)$, for viscosity, the mean energy of thermal motion, $g(y) = \langle\varepsilon\rangle = c_V m_0 T$ (c_V is the specific heat capacity at constant volume), for heat conduction, and the relative concentration of selected molecules, $g(y) = n_1(y)/n$, for diffusion. Let us assume that each molecule transfers a certain (average) amount of the quantity g through a given surface; this amount of g was acquired by the molecule at its latest collision. Then the flux density of g in the y-direction can be calculated using the formula

$$G = -\frac{1}{3} n\langle v\rangle \lambda \frac{dg}{dy}. \tag{P2.9.2.4}$$

For rough estimates, it can be assumed that the particles move with velocity $\langle v\rangle$ in one of the six directions determined by the coordinate axes. Then the particle flux through a unit area is equal to $n\langle v\rangle$. It can also be assumed that the particles crossing the area the y-level experienced their latest collision at an average distance λ (Fig. P2.9). Then we have $G \approx \frac{1}{6} n\langle v\rangle [g(y-\lambda) - g(y+\lambda)]$, and hence $G \approx \frac{1}{3} n\langle v\rangle \lambda (dg/dy)$.

► **Formulas for transfer coefficients in a gas.**

1. Substituting $g = m_0 v_x$ into (P2.9.2.4), gives the momentum flux, which is equal to the frictional force (P2.9.2.1) for a unit area. Then the coefficient of viscosity is expressed as

$$\eta = \tfrac{1}{3} n m_0 \langle v\rangle \lambda = \tfrac{1}{3} \rho \langle v\rangle \lambda. \tag{P2.9.2.5}$$

2. Substituting $g = c_V m_0 T$ into (P2.9.2.4) and comparing with (P2.9.2.2), we find the thermal conductivity:

$$\kappa = \tfrac{1}{3} n m_0 \langle v \rangle c_V \lambda = \tfrac{1}{3} \rho \langle v \rangle c_V \lambda. \qquad \text{(P2.9.2.6)}$$

3. Substituting $g = n_1/n$ into (P2.9.2.4) and comparing with (P2.9.2.3) yields the diffusivity:

$$D = \tfrac{1}{3} \langle v \rangle \lambda. \qquad \text{(P2.9.2.7)}$$

There are two important conclusions that can be drawn from formulas (P2.9.2.5)–(P2.9.2.7):

1) The mean free path is inversely proportional to ρ, which can be seen from equation (P2.9.1.2); hence, the viscosity and thermal conductivity of gases at a given fixed temperature are pressure independent (Maxwell's law). This conclusion holds true as long as the mean free path is small compared to the container size.

2) The ratio between the viscosity and the thermal conductivity is temperature independent.

► **Extremely rarefied gas.** When the mean free path becomes commensurable with the container size (*rarefied gas*), the viscosity and thermal conductivity begin to depend on density. For example, consider the heat transfer between two walls having temperatures T_1 and T_2 and separated by a distance $d \ll \lambda$ (*extremely rarefied gas*). It can be assumed that, after its collision with the wall having the temperature T_1, each molecule acquires (on the average) the energy $c_V m_0 T_1$, then flies without collisions to the opposite wall and gives up the energy $c_V m_0 (T_2 - T_1)$. It follows from (P2.5.1.3) that the number of molecules reaching the wall in time Δt is equal to $\frac{1}{4} n \langle v \rangle S \Delta t$. Consequently, $q = \frac{1}{4} \rho \langle v \rangle c_V \Delta T$, and hence $\kappa = \frac{1}{4} \rho \langle v \rangle c_V d$.

Chapter P3

Electrodynamics

P3.1. Electric Charge. Coulomb's Law

P3.1.1. Electric Charge and Its Properties

► **Electric charge** is a scalar physical quantity that determines the electromagnetic interaction of subatomic particles. In SI, the unit of charge is the *coulomb* (C); it is defined in terms of the unit of electric current, the *ampere* (A): 1 C = 1 A s.

Properties of electric charge:

1. The carriers of electric charge are many subatomic particles such as protons and electrons (as well as antiprotons and positrons) and some metastable particles as π-mesons, K-mesons, muons, etc. Charged particles interact with each other with forces that decay with the distance as slowly as gravitational forces but are much stronger in magnitude.

2. Proton and electron and many other charged subatomic particles have the same electric charge in magnitude. This charge is called the *elementary charge* and denoted e. In SI, $e = 1.602\times 10^{-19}$ C. As experiments have shown, the charge of subatomic particles is independent of their velocity.

3. The charge of subatomic particles can be either positive or negative. Particles with like charges repel one another and particles with unlike charges attract. By convention, the charge of a proton is positive ($+e$) and the charge of an electron is negative ($-e$).

If a macroscopic body includes different numbers of electrons, N_e, and protons, N_p, the body is charged and its charge is always multiple of the elementary charge: $q = e(N_p - N_e)$.

► **Law of conservation of electric charge.** A system is called *electrically closed* if it does not exchange charges with external bodies, which means that charges do not cross its boundary. The total charge of an electrically closed system, or the algebraic sum of all its charges, remains constant. This statement is obvious if there are no elementary particle reactions. However, the law of conservation of charge is fundamental—it holds even if charged particles are created or destroyed.

► **Charge distribution.** The spatial distribution of charge is characterized by its *volume density* $\rho(\mathbf{r})$, measured in $\mathrm{C/m^3}$, *surface density* $\sigma(\mathbf{r})$, measured in $\mathrm{C/m^2}$, and *linear density* $\lambda(\mathbf{r})$, measured in $\mathrm{C/m}$. We have

$$dq = \rho\, dV, \qquad dq = \sigma\, dS, \qquad dq = \lambda\, dl. \tag{P3.1.1.1}$$

► **Dipole. Dipole moment.** A system of charges is called *electrically neutral* if its net charge is zero. An *electric dipole* is a simple example of an electrically neutral system; it consists of two point charges, q and $-q$, separated by a distance l. The *electric dipole moment* is a vector quantity defined as

$$\mathbf{p} = q\mathbf{l}, \tag{P3.1.1.2}$$

where $\mathbf{l} = \mathbf{r}_+ - \mathbf{r}_-$ is the displacement vector from the charge $-q$ to the charge q. The dipole moment is measured in C m.

The following definition is a generalization to the case of an electrically neutral system:

$$\mathbf{p} = \sum_i q_i \mathbf{r}_i = q(\mathbf{r}_+ - \mathbf{r}_-),$$

where $q = \sum_{q_i>0} q_i$ is the sum of all positive charges, $\mathbf{r}_+ = \sum_{q_i>0} q_i \mathbf{r}_i / q$ is the center of positive charges, and $\mathbf{r}_- = -\sum_{q_i<0} q_i \mathbf{r}_i / q$ is the center of negative charges.

P3.1.2. Coulomb's Law

Coulomb's law describes the electrostatic interaction of *point charges*, i.e., charged particles and bodies whose dimensions can be neglected as compared to the distances between them. Coulomb's law states that, in vacuum, the electrostatic force, F, acting on a point charge q_1 due to the presence of a point charge q_2 is directly proportional to each of the charges and inversely proportional to the square of the distance r between them:

$$F = k\frac{|q_1|\,|q_2|}{r^2}, \qquad \text{(P3.1.2.1)}$$

where k is the proportionality coefficient, dependent on the unit system chosen. The force is directed along the straight line connecting the point charges; like charges repel and unlike charges attract.

In SI, the coefficient in (P3.1.2.1) equals $k = 9.0 \times 10^9\ \mathrm{N\,m^2/C^2}$. Also $k = 1/(4\pi\varepsilon_0)$, where $\varepsilon_0 = 8.85 \times 10^{-12}\ \mathrm{F/m}$ is the *electric constant*. In Gaussian units (CGS system), k is taken to be equal to one and the unit of charge is defined by Coulomb's law.

The electrostatic force acting on a charge q due to the presence of many point charges, $Q_1, Q_2, \ldots$, equals the linear vector superposition of forces

$$\mathbf{F} = \sum_i k\frac{qQ_i}{(\mathbf{r} - \mathbf{r}_i)^2}\,\frac{\mathbf{r} - \mathbf{r}_i}{|\mathbf{r} - \mathbf{r}_i|}, \qquad \text{(P3.1.2.2)}$$

where $\mathbf{r}$ is the position vector of the charge q and $\mathbf{r}_i$ is the position vector of the charge Q_i $(i = 1, 2, \ldots)$.

► **On unit conventions in electrostatics.** In what follows, all formulas will be given in SI. To convert to Gaussian units (CGS system), it will be sufficient to set $k = 1$ in most cases; if a formula contains ε_0, one should first replace ε_0 with $1/(4\pi k)$.

P3.2. Electric Field. Strength and Potential

P3.2.1. Strength of Electric Field

► **Electromagnetic field.** The interaction between charged particles is implemented through *electromagnetic field*. This means that: (a) a charged particle generates an electromagnetic field in the surrounding space and (b) the electromagnetic field exerts a force on other charged particles. The field generated by a point charge is proportional to its charge; the force exerted by the field on a particle is proportional to the charge of this particle.

► **Electric field.** An electromagnetic field is a combination of an *electric field* and a *magnetic field*, which are closely related to each other. The action of an electric field on a charged particle does not depend on the particle velocity and that of a magnetic field does. The sources of electric fields are any charged particles, while magnetic fields are generated by moving charges. The proportion between electric and magnetic fields changes when passing from one inertial frame to another. The properties of electric and magnetic fields are completely determined by Maxwell's equations (see Subsection P3.11.1). Maxwell's equations are invariant under relativistic, Lorentz transformations.

► **Test charge. Strength of an electric field.** The characteristics of an electromagnetic field are studied using the concept of a *test charged particle*, which is an idealized small object whose dimensions and charge are small enough so that, when placed into a field of interest, it does not distort the field (does not change the positions of the field sources). The force acting on a stationary test particle of charge q is proportional to the charge and is only determined by the electric field:

$$\mathbf{F}_q = q\mathbf{E}. \qquad \text{(P3.2.1.1)}$$

This formula defines the *strength of an electric field*, **E**. It also answers the question what force the field exerts on any charge q, moving or stationary. In SI, the strength of an electric field is measured in N/C or V/m. For brevity, the term electric field is used to mean the strength of an electric field whenever this does not lead to confusion.

► **Electrostatic field. Principle of superposition.** A stationary electric field generated by a system of stationary charges is called an *electrostatic field*. The strength of an electrostatic field can be determined using Coulomb's law (P3.1.2.2).

1. *Electric field of a point charge.* If a point charge q is placed in the field of a point charge Q, then it follows from (P3.1.2.2) and (P3.2.1.1) that

$$\mathbf{E} = k\frac{Q}{r^2}\frac{\mathbf{r}}{r} = E_r\frac{\mathbf{r}}{r}, \qquad \text{(P3.2.1.2)}$$

where E_r is the projection of **E** onto the radial direction.

2. *Electric field of a system of point charges.* Using the principle of superposition, we get

$$\mathbf{E} = \mathbf{E}_1 + \mathbf{E}_2 + \cdots = \sum_i k\frac{Q_i}{(\mathbf{r}-\mathbf{r}_i)^2}\frac{\mathbf{r}-\mathbf{r}_i}{|\mathbf{r}-\mathbf{r}_i|}. \qquad \text{(P3.2.1.3)}$$

For a continuously distributed charge, the summation must be replaced by integration (see (P3.1.1.1)). (Compare with the formulas for the gravitational field in Subsection P1.7.2.)

Example 1. There is a charge continuously distributed along an arc of a circle of radius R with a linear density λ (Fig. P3.1). The arc angle is $2\alpha_0$. Find the strength of the electric field generated by the charge, at the circle center.

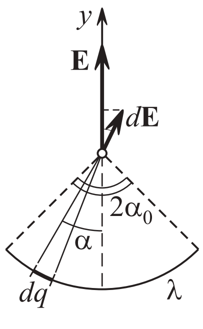

Figure P3.1. Strength of the electric field generated by a charged arc of a circle.

Solution. By symmetry, the field strength is directed along the y-axis, which passes through the midpoint of the arc and the circle center O. The strength of the field generated by the arc element $d\alpha$ at O equals $dE = k\,dq/R^2$, where $dq = \lambda R\,d\alpha$. Projecting onto y and integrating yields

$$E = E_y = \int_{-\alpha_0}^{\alpha_0} k\frac{\lambda R\,d\alpha}{R^2}\cos\alpha = k\frac{2\lambda\sin\alpha_0}{R}.$$

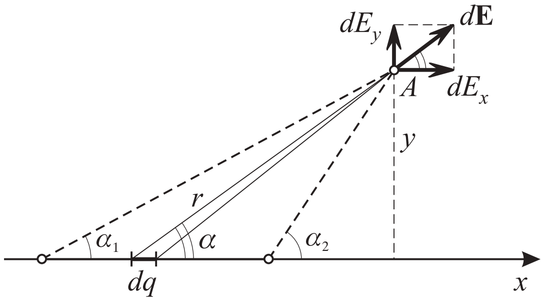

Figure P3.2. Strength of the electric field generated by a charged segment.

Example 2. Field of a segment. A charge is evenly distributed along a segment with a linear density λ. Find the field strength at the point A whose position is determined by the distance y to the straight line of the segment and two angles α_1 and α_2 as shown in Fig. P3.2.

Solution. The contribution of the element dx to the field strength at A equals $dE = k\lambda\,dx/r^2$, where r is the distance from dx to A. The respective projections on the x- and y-axes are $dE\cos\alpha$ and $dE\sin\alpha$. It is convenient to integrate with respect to the angle α. Substituting $r = y/\sin\alpha$ and $x = -y\cot\alpha$, with $dx = y\,d\alpha/\sin^2\alpha$, and integrating, we obtain the following expressions of E_x and E_y:

$$E_x = k\frac{\lambda}{y}(\sin\alpha_2 - \sin\alpha_1), \qquad E_y = k\frac{\lambda}{y}(\cos\alpha_1 - \cos\alpha_2).$$

If $\alpha_1 = \pi - \alpha_2 = \alpha$ (the point A lies on the straight line perpendicular to the segment through its midpoint), then $E_x = 0$ and $E_y = 2k\lambda\cos\alpha/y$. If $\alpha \to 0$ (the segment becomes a straight line), then $E_y = 2k\lambda/y$. If $\alpha_1 = 0$ and $\alpha_2 = \pi/2$ (a ray), then $E_x = E_y = k\lambda/y$.

P3.2.2. Potential of an Electrostatic Field

► **Definition of potential.** An electrostatic field is *potential* (see Subsection P1.5.3) just as any static central field. This means that the work done by the field to move a test charge from one point in space to another is independent of the path. This allows us to define the *potential of an electrostatic field*, $\varphi(\mathbf{r})$. We have

$$A_q(1 \to 2) = W_q(\mathbf{r}_1) - W_q(\mathbf{r}_2) = q\bigl[\varphi(\mathbf{r}_1) - \varphi(\mathbf{r}_2)\bigr], \qquad \text{(P3.2.2.1)}$$

where $A_q(1 \to 2)$ is the work done by the field to transfer the charge q from point $\mathbf{r}_1$ to point $\mathbf{r}_2$, $W_q(\mathbf{r}) = q\varphi(\mathbf{r})$ is the *potential energy of the charge in the electrostatic field* (throughout this chapter, energy will be denoted by W). The scalar quantity $\varphi(\mathbf{r}_1) - \varphi(\mathbf{r}_2)$ is called the *potential difference* between points $\mathbf{r}_1$ and $\mathbf{r}_2$. For $W_q(\mathbf{r})$ and $\varphi(\mathbf{r})$ to be uniquely defined, one has to choose a point where they are zero. In SI, potential is measure in volts (V).

► **Relation between field strength and potential.** Given the field strength $\mathbf{E}(\mathbf{r})$, one can determine the potential difference and potentials as

$$\varphi(\mathbf{r}_1) - \varphi(\mathbf{r}_2) = \int_{\mathbf{r}_1}^{\mathbf{r}_2} \mathbf{E}\,d\mathbf{r}, \qquad \varphi(\mathbf{r}) = \int_{\mathbf{r}}^{\mathbf{r}_0} \mathbf{E}\,d\mathbf{r}, \qquad \text{(P3.2.2.2)}$$

where $\mathbf{r}_0$ is the reference point where the potential is taken to be zero. Given the potential $\varphi(\mathbf{r})$, one can find the projection of the field strength onto any direction l (based on (P3.2.2.2) for two close points):

$$E_l = -\frac{\partial\varphi}{\partial l}. \qquad \text{(P3.2.2.3)}$$

Consequently, we can find the field strength vector:

$$\mathbf{E} = -\operatorname{grad}\varphi = -\left(\mathbf{i}\frac{\partial\varphi}{\partial x} + \mathbf{j}\frac{\partial\varphi}{\partial y} + \mathbf{k}\frac{\partial\varphi}{\partial z}\right), \qquad \text{(P3.2.2.4)}$$

where $\mathbf{i}$, $\mathbf{j}$, and $\mathbf{k}$ are the unit vectors of the respective coordinate axes.

► Principle of superposition for potential.

1. The *potential of the field of a point charge* Q can be calculated using (P3.2.2.3):

$$E_r = -\frac{d\varphi}{dr} \quad\Longrightarrow\quad \frac{d\varphi}{dr} = -k\frac{Q}{r^2} \quad\Longrightarrow\quad \varphi(r) = k\frac{Q}{r} + \text{const.}$$

Usually, the potential is taken to be zero at infinity. In this case,

$$\varphi(r) = k\frac{Q}{r}. \tag{P3.2.2.5}$$

2. The *potential of the field of a system of point charges* equals the algebraic sum of the potentials of individual charges (principle of superposition for potential):

$$\varphi(\mathbf{r}) = \varphi_1(\mathbf{r}) + \varphi_2(\mathbf{r}) + \cdots, \qquad \varphi(\mathbf{r}) = \sum_i k\frac{Q_i}{|\mathbf{r}-\mathbf{r}_i|}. \tag{P3.2.2.6}$$

For a continuously distributed charge, the summation must be replaced by integration.

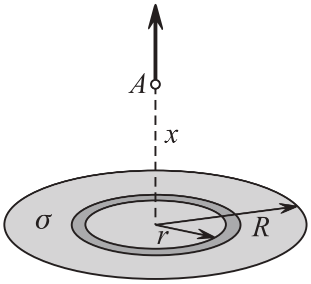

Figure P3.3. To the calculation of the electrostatic field of a charged disk.

Example 1. Field of a disk. A thin disk of radius R is evenly charged with a surface density σ. Find the potential and field strength at the point A located on the disk axis at a distance x from the center (Fig. P3.3).

Solution. The contribution of a thin ring bounded by the circles of radii r and $r + dr$ is

$$d\varphi = k\frac{dq}{\sqrt{x^2+r^2}} = k\frac{\sigma\, 2\pi r\, dr}{\sqrt{x^2+r^2}};$$

note that all points of the ring are essentially at the same distance to A. Integrating yields the desired potential

$$\varphi = \int_0^R k\frac{\sigma\, 2\pi r\, dr}{\sqrt{x^2+r^2}} = 2k\pi\sigma\bigl(\sqrt{x^2+R^2} - x\bigr).$$

Using (P3.2.2.3), we find the field strength (it is directed along x):

$$E_x = -\frac{d\varphi}{dx} = 2\pi k\sigma\left(1 - \frac{x}{\sqrt{x^2+R^2}}\right).$$

In the limit $R \to \infty$, we arrive at the field strength of a plane: $E_x = 2\pi k\sigma = \sigma/(2\varepsilon_0)$.

Example 2. Field of a dipole. Find the potential and field strength far away from a dipole shown in Fig. P3.4.

Solution. The potential at a remote point determined by $\mathbf{r}$ ($r = |\mathbf{r}| \gg l$) equals

$$\varphi(\mathbf{r}) = \frac{kq}{r_1} - \frac{kq}{r_2} \approx \frac{kq}{r-s} - \frac{kq}{r+s} \approx k\frac{(\mathbf{p}\cdot\mathbf{r})}{r^3},$$

where $s = \bigl(\frac{1}{2}\mathbf{l}\cdot\frac{1}{r}\mathbf{r}\bigr)$ and $\mathbf{p} = q\mathbf{l}$ (see Subsection P3.1.1).

The field strength can be found using the identities $\operatorname{grad}(1/r^3) = -3\mathbf{r}/r^5$ and $\operatorname{grad}(\mathbf{p}\cdot\mathbf{r}) = \mathbf{p}$. We have

$$\mathbf{E} = -\operatorname{grad}\varphi = k\left[\frac{3(\mathbf{p}\cdot\mathbf{r})\mathbf{r}}{r^5} - \frac{\mathbf{p}}{r^3}\right]. \tag{P3.2.2.7}$$

It follows that the magnitude of the field strength equals $E = kpr^{-3}\sqrt{3\cos^2\theta + 1}$.

The same expressions hold true for any electrically neutral system with a nonzero dipole moment (see Subsection P3.1.1) at large distances.

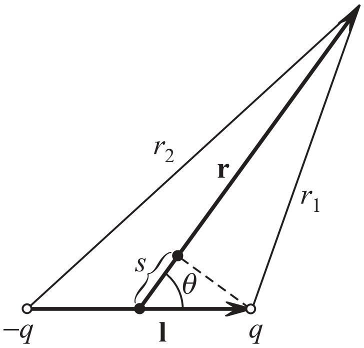

Figure P3.4. To the calculation of the field of a dipole.

► **Dipole in an external field.** A small dipole with dipole moment $\mathbf{p} = q\mathbf{l}$ in an external electrostatic field has the potential energy

$$W_\text{p} = q\varphi(\mathbf{r}_+) - q\varphi(\mathbf{r}_-) = q\frac{\partial\varphi}{\partial l}l = -pE_l = -(\mathbf{p}\cdot\mathbf{E}). \qquad \text{(P3.2.2.8)}$$

This energy changes if the dipole is turned by an angle—the field exerts a rotational moment on the dipole:

$$\mathbf{M} = \mathbf{l}\times(q\mathbf{E}) = \mathbf{p}\times\mathbf{E}, \qquad \text{(P3.2.2.9)}$$

The energy also changes if the dipole moves in a nonuniform field—the field exerts the force

$$\mathbf{F} = q\mathbf{E}(\mathbf{r}_+) - q\mathbf{E}(\mathbf{r}_-) = q\frac{\partial\mathbf{E}}{\partial l}l = p\frac{\partial\mathbf{E}}{\partial l} = p_x\frac{\partial\mathbf{E}}{\partial x} + p_y\frac{\partial\mathbf{E}}{\partial y} + p_z\frac{\partial\mathbf{E}}{\partial z}. \qquad \text{(P3.2.2.10)}$$

An equilibrium orientation with minimum potential energy corresponds to $\mathbf{p}\parallel\mathbf{E}$. A dipole oriented along the field strength vector is pulled into an area where the field is stronger.

P3.3. Gauss's Theorem

P3.3.1. Statement of the Theorem

► **Flux of electric field.** The flux of the electric field $\mathbf{E}$ through a plane area element ds is defined as

$$d\Phi = (\mathbf{E}\cdot d\mathbf{s}) = E_n ds = E\cos\theta\, ds, \qquad \text{(P3.3.1.1)}$$

where $d\mathbf{s} = \mathbf{n}\,ds$, $\mathbf{n}$ is a normal vector to the plane, θ is the angle between $\mathbf{E}$ and $\mathbf{n}$, $E_n = E\cos\theta$ is the projection of $\mathbf{E}$ onto the normal $\mathbf{n}$. The sign of $d\Phi$ depends on how the normal direction is chosen. The flux of the field $\mathbf{E}$ through a finite surface S is determined as

$$\Phi = \int_S E_n\, ds. \qquad \text{(P3.3.1.2)}$$

If the surface is closed, the normal is taken to point outward.

Flux additivity: if an electrostatic field is a superposition of several fields, $\mathbf{E}(\mathbf{r}) = \sum_i \mathbf{E}_i$, then $\Phi = \sum_i \Phi_i$ for any surface.

The flux of the electric field generated by point charge Q through an area ds is

$$d\Phi = E_r\cos\theta\, ds = \pm k\frac{Q}{r^2}\, ds_\perp = \pm kQ\, d\Omega,$$

where $ds_\perp = |ds\cos\theta|$ is the projection of ds onto the plane perpendicular to **r**, and $d\Omega = ds_\perp/r^2$ is the solid angle at which the area ds is seen from the charge Q. The plus sign corresponds to an acute angle between **n** and **r**, and the minus sign corresponds to an obtuse angle. The field flux through a closed surface is equal to $4\pi kQ$ if the charge is inside the surface, and zero if it is outside.

► **Gauss's theorem.** The flux of an electrostatic field through a closed surface is only determined by the net charge, $q_{\rm enc}$, enclosed within the surface:

$$\Phi = 4\pi k q_{\rm enc} = \frac{q}{\varepsilon_0}. \tag{P3.3.1.3}$$

► **Gauss's theorem and electric field lines.** Electric field lines are useful to visualize electric fields. These are drawn using the following rules: (a) the tangent to a field line is directed along the vector **E** at every point in space and (b) the density of field lines is proportional to the magnitude of the field at point of interest. The field flux through a surface is proportional to the number of field lines piercing the surface. (Lines of any vector field can be introduced likewise.) Gauss's theorem implies that the electric field lines must start and finish at charges and also they must be continuous in an empty space. It is noteworthy that Gauss's theorem and continuity of field lines are corollaries of the fact that the Coulomb force decays with distance as $1/r^2$.

Apart from field lines, *equipotential surfaces* are also used for visualization of electric fields. Equipotential surfaces are everywhere perpendicular to field lines (the work done by the field to transfer a test charge along such a surface must be zero).

P3.3.2. Application of Gauss's Theorem

► **Calculating the field using Gauss's theorem.** Suppose, from symmetry considerations, it is possible to construct an imaginary surface such that **E** is perpendicular to it and constant in magnitude on some part of the surface and is parallel to the surface (**E** $\perp$ **n**) on the other part. Such a surface is called a *Gaussian surface*. Gauss's theorem can be applied to this surface to find the field magnitude E.

Example 1. Field of a charged string. Find the electric field generated by an infinitely long, evenly charged straight string (Fig. P3.5).

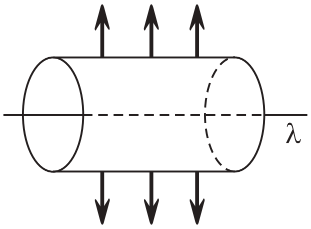

Figure P3.5. To the calculation of the electric field generated by an infinite string using Gauss's theorem.

Solution. The electric field is perpendicular to the string at any point in space. The field magnitude E_r is only dependent on the distance r to the string. Evidently, any cylinder of radius r with generatrix of length l and the axis lying on the string, can be taken as a Gaussian surface. Writing Gauss's theorem (P3.3.1.2), we find

$$E_r\,2\pi rl = \frac{\lambda l}{\varepsilon_0} \quad\Longrightarrow\quad E_r = \frac{\lambda}{2\pi\varepsilon_0 r} = \frac{2k\lambda}{r}$$

(cf. example 2 from Subsection P3.2.1). The potential difference between two points equals

$$\varphi_1 - \varphi_2 = \frac{\lambda}{2\pi\varepsilon_0}\ln\frac{r_2}{r_1}.$$

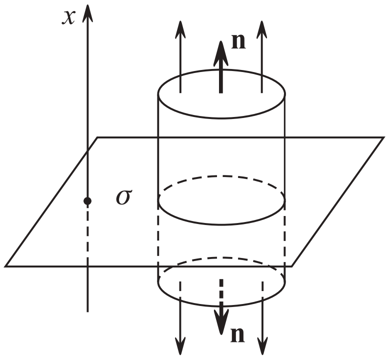

Figure P3.6. To the calculation of the electric field generated by a charged plane using Gauss's theorem.

Example 2. Field of a charged plane. Find the electric field generated by an evenly charged plane (Fig. P3.6).

Solution. The field is everywhere perpendicular to the plane and E_x is only dependent on the distance to the plane. A right cylinder whose bases of area S are symmetric with respect to the plane can be taken as a Gaussian surface. The field flux through this surface equals $E_x(x)S - E_x(-x)S = 2E_xS$. Writing Gauss's theorem, we find that

$$2E_xS = \frac{\sigma S}{\varepsilon_0} \quad\Longrightarrow\quad E_x(x) = -E_x(-x) = \frac{\sigma}{2\varepsilon_0}$$

(see example 1 from Subsection P3.2.2). Taking $\varphi = 0$ at $x = 0$, we have $\varphi(x) = \dfrac{\sigma}{2\varepsilon_0}|x|$.

Example 3. Field of a charged ball. Find the electric field of a uniformly charged ball of radius R with charge q.

Solution. The field of a uniformly charged ball is a central field. A concentric sphere of radius r can be taken as a Gaussian surface. If $r > R$, then the surface encloses the entire ball and so $q_{\rm enc} = q$. Hence, $E_r\,4\pi r^2 = q/\varepsilon_0$. If $r < R$, then $q_{\rm enc} = qr^3/R^3$ and hence $E_r\,4\pi r^2 = qr^3/(\varepsilon_0 R^3)$. Finally, we have

$$\mathbf{E} = \begin{cases} k\dfrac{q}{r^2}\dfrac{\mathbf{r}}{r} = \dfrac{\rho R^3}{3\varepsilon_0 r^2}\dfrac{\mathbf{r}}{r} & \text{for } r > R, \\ k\dfrac{q\mathbf{r}}{R^3} = \dfrac{\rho\mathbf{r}}{3\varepsilon_0} & \text{for } r < R, \end{cases}$$

where ρ is the charge density. The radial component of the field equals $E_r = -d\varphi/dr$ (see Subsection P3.2.2). Hence,

$$\varphi = \begin{cases} k\dfrac{q}{r} & \text{for } r > R, \\ -k\dfrac{qr^2}{2R^3} + \text{const} = -k\dfrac{qr^2}{2R^3} + \dfrac{3}{2}k\dfrac{q}{R} & \text{for } r < R. \end{cases}$$

The unknown constant is determined from the continuity condition for the potential at the ball surface.

► **Earnshaw's theorem.** Earnshaw's theorem is a corollary of Gauss's theorem. It states that a charged particle in vacuum cannot be in a stable equilibrium under the action of electric forces only. Indeed, if this were the case, the electric fields generated by the other charges would all have to point inward a small sphere enclosing the particle (if its charge is positive). But this would contradict Gauss's theorem (all other charges are outside the sphere).

► **Maxwell's equations in electrostatics.** The condition that an electrostatic field must be potential,

$$\oint \mathbf{E}\cdot d\mathbf{r} = 0 \quad\Longrightarrow\quad \operatorname{curl}\mathbf{E} = \mathbf{0},$$

is one of Maxwell's equations (in integral and differential forms) written for the special case of electrostatics.

The second equation is Gauss's theorem (written for a spatially distributed charge):

$$\oint \mathbf{E}\cdot d\mathbf{s} = \frac{1}{\varepsilon_0}\int \rho\, dV \quad\Longrightarrow\quad \operatorname{div}\mathbf{E} = \frac{\rho}{\varepsilon_0}.$$

Substituting $\mathbf{E} = -\operatorname{grad}\varphi$ in the last equation yields *Poisson's equation for electric potential*:

$$\operatorname{div}\operatorname{grad}\varphi = -\frac{\rho}{\varepsilon_0}, \qquad \text{or} \qquad \Delta\varphi = -\frac{\rho}{\varepsilon_0}.$$

P3.4. Conductors and Capacitors

P3.4.1. Electrostatics of Conductors

► **Field in a conductor. The potential of a conductor.** A conductor is a material that is capable of carrying electric current. To this end, the material must contain movable electric charges that can travel across. Electrostatics deals with states where charges are at equilibrium, when there is no directed motion of charged particles—electric current. This means that the electric field must be zero everywhere within the conductor. It follows that:

1. The potential of all point within the conduction has the same value, which is called the *potential of the conductor*.

2. The conductor surface is an equipotential surface. The electric field lines are perpendicular to it.

3. The volume charge density in the conductor is zero (it follows from Gauss's theorem that it must be zero charge in any volume within the conductor). The uncompensated charges must be distributed on the surface.

4. The electric field near the conductor surface is related to the local surface charge density σ by

$$E = \frac{\sigma}{\varepsilon_0}. \qquad \text{(P3.4.1.1)}$$

This formula can be obtained from Gauss's theorem (P3.3.1.3) by taking as a Gaussian surface a small cylinder whose one base is outside the conductor but near its surface and the other is inside. Then we get $ES = \sigma S/\varepsilon_0$.

► **Isolated conductor.** The potential of an isolated conductor is proportional to its charge:

$$\varphi = \frac{1}{C}q, \qquad \text{(P3.4.1.2)}$$

where C is the *capacitance* of the conductor; it depends on the shape and size of the conductor and the dielectric permittivity of the surrounding medium. In SI, the unit of capacitance is the *farad* (F). In CGS, capacitance is measured in centimeters (cm). For example, the potential and capacitance of an isolated ball of radius R equal

$$\varphi = \frac{1}{4\pi\varepsilon_0}\frac{q}{R}, \quad C = 4\pi\varepsilon_0 R. \qquad \text{(P3.4.1.3)}$$

► **Connection of conductors.** When two conductors having different potentials are connected to each other with a conducting wire, their potentials become equal. If the conductors are sufficiently far away from each other, their individual potentials can be calculated as the potential of an isolated conductor. Then the law of conservation of electric charge allows us to find the resulting common potential, φ':

$$C_1\varphi_1 + C_2\varphi_2 = C_1\varphi' + C_2\varphi' \quad\Longrightarrow\quad \varphi' = \frac{C_1\varphi_1 + C_2\varphi_2}{C_1 + C_2}$$

(the capacitance of the wire and its charge may be neglected). If the capacitance of one conductor is much larger than that of the other, its potential remains almost unchanged. For example, if a conductor is connected to the earth (it is said to be earthed), its potential becomes equal to the Earth's potential, which is constant and usually taken to be zero.

► **Conductor in an external electric field.** When any conductor is placed in an external electric field, its movable charges redistribute so that the resulting field (superposition of the external and internal fields) within the conductor is zero. For example, if a positive point charge is brought near an uncharged conductor, then negative charges will gather on the side that is closer to the charge and positive charges will move to the side that is further away. As a result, the charge and conductor will attract. (This phenomenon is called *electrostatic induction*.) Since the charge distribution on the conductor surface is usually unknown, the principle of superposition becomes unsuitable for the calculation of the resulting field. Sometimes, the problem may be solved by indirect techniques.

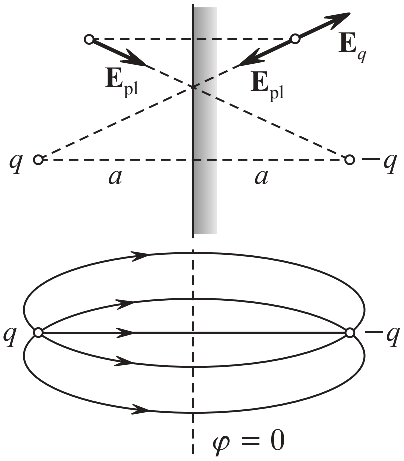

Figure P3.7. Calculation of the field by the electrostatic image method.

Example 1. Let us bring a positive point charge q near the surface of an earthed conductor to a small distance a compared to the conductor size. In this case, the conductor can be replaced by an infinite conducting half-space (Fig. P3.7). There will be induced negative charges at the plane surface. It is required to find the field $\mathbf{E}_{\rm pl}$ produced by these charges at any point of the free space. Note that the charge distribution is unknown!

To begin with, let us find the field $\mathbf{E}_{\rm pl}$ inside the conductor at the point symmetric to an outside point of interest. The field $\mathbf{E}_{\rm pl}$ will compensate the field produced by the charge q at this point. Hence, the field $\mathbf{E}_{\rm pl}$ inside will exactly coincide with that generated by an imaginary charge $-q$ placed at the same point as q. Now we see that the field $\mathbf{E}_{\rm pl}$ produced by the surface charges of the conductor is symmetric relative to the plane. Consequently, $\mathbf{E}_{\rm pl}$ *outside* will exactly coincide with the field produced by the imaginary charge $-q$ placed *symmetrically relative to the charge* q. This symmetric charge is called the *image* of the charge q and the method is known as the *electrostatic image method*. It is now fairly easy to find: (a) the attractive force between the charge and the conductor, $F = kq^2/(2a)^2$, (b) the electric field everywhere outside the conductor (it is equal to the field produced by the charge q and its image $-q$), and (c) the charge distribution of the surface—once the field near the surface is known, we can find the charge density σ using formula (P3.4.1.1).

► **Principle of uniqueness.** The principle of uniqueness is useful in solving problems with unknown charge distribution. This principle states that for a system of conductors, there exists a unique surface charge distribution and a unique field $\mathbf{E}(\mathbf{r})$ such that the net fields inside the conductors vanish and their potentials and charges acquire prescribed values. If one guesses a charge distribution or a field configuration that satisfies the above conditions, it will be the correct solution. For example, one can notice that the equipotential surface $\varphi = 0$ of the field produced by two charges, q and $-q$, coincides with their symmetry plane (see Fig. P3.7). Then it can be inferred that the fields produced by the charge q and it image $-q$ coincides with that produced by the charge q and the induced charge of the conducting plane (see the preceding example).

Example 2. A conducting ball in a uniform field. Consider an uncharged conducting ball of radius R in a unform field $\mathbf{E}_0$. The induced charges on the ball will redistribute so as to generate the field $-\mathbf{E}_0$ inside the ball. In order to obtain this distribution, consider two imaginary balls of the same radius but having a uniform volume charge, one of density ρ and the other of density $-\rho$. (The field of a uniformly charged ball was considered in example 3 from Subsection P3.3.2.) If the center of the positively charged ball is slightly displaced by **l** relative to the center of the negatively charged ball (Fig. P3.8), then the field in the overlapping region is

$$\mathbf{E} = -\frac{\rho\mathbf{r}}{3\varepsilon_0} + \frac{\rho(\mathbf{r}-\mathbf{l})}{3\varepsilon_0} = -\frac{\rho\mathbf{l}}{3\varepsilon_0},$$

and hence is uniform. The charge inside the overlapping region is zero. Now by letting $\mathbf{l} \to \mathbf{0}$ and $\rho \to \infty$ so that $\rho\mathbf{l}/(3\varepsilon_0) = \mathbf{E}_0$, we obtain the desired induced charge distribution: $\sigma = \sigma_0 \cos\theta$, where $\sigma_0 = \rho l = 3\varepsilon_0 E_0$. Also, we find the field the induced charges produce outside the ball. It coincides with that produced by a point dipole with the dipole moment $\mathbf{p} = (\rho V)\mathbf{l} = 4\pi\varepsilon_0 R^3 \mathbf{E}_0$ (see example 2, Subsection P3.2.2).

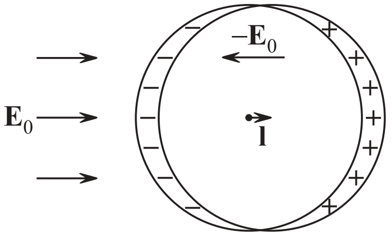

Figure P3.8. To the calculation of induced charges on a conducting ball in a uniform electric field.

P3.4.2. Capacitors

► **Capacitance of a capacitor.** A *capacitor* is an object consisting of a pair of insulated conductors, one of which having a charge $+q$ and the other the charge $-q$. The conductors are often called the *plates* of the capacitor. The charge q is called the *capacitor charge*. The potential difference between the positive and negative plates, U, is called the *capacitor voltage*. The voltage is proportional to the capacitor charge:

$$U = \frac{1}{C}q, \tag{P3.4.2.1}$$

where C is the *electric capacitance* (or just *capacitance*) of the capacitor.

► **Simple capacitors.** A capacitor is called simple if: (a) its electric field is concentrated within a limited region between the plates (so it can be assumed that all field lines start at the positive plate and finish at the negative one), (b) the whole region where the field is concentrated is filled with a dielectric material having a dielectric permittivity ε. (A dielectric weakens the electric field by a factor of ε; see Subsection P3.5.1.)

Example 1. Parallel-plate capacitor. A parallel-plate capacitor is one in which the conductors are parallel plates of area S each separated by a small distance b as compared to the plate size ($b \ll \sqrt{S}$). The electric field between the plates can be regarded as uniform everywhere except for the very edges. The field can be found using formula (P3.4.1.1): $E = q/(\varepsilon_0\varepsilon S)$. The voltage of a parallel-plate capacitor equals $U = Eb$ and its capacitance is

$$C = \frac{\varepsilon_0\varepsilon S}{b}. \tag{P3.4.2.2}$$

Example 2. Spherical capacitor. In a spherical capacitor, its plates are concentric spheres of radii R_1 and R_2. The field between the plates is $E = \dfrac{q}{4\pi\varepsilon_0\varepsilon r^2}$, where r is the distance to the center. The voltage is expressed as $U = \int_{R_1}^{R_2} E(r)\,dr$ and the capacitance equals

$$C = \frac{4\pi\varepsilon_0\varepsilon R_1 R_2}{R_2 - R_1}.$$

For $R_2 \to \infty$, this expression reduces to the capacitance of an isolated sphere (see formula (P3.4.1.3)).

Example 3. Cylindrical capacitor. In a cylindrical capacitor, its plates are concentric cylinders of radii R_1 and R_2 with length $l \gg R_2 - R_1$. The field between the plates is $E = \dfrac{q}{2\pi\varepsilon_0\varepsilon r l}$. The voltage is given by $U = \int_{R_1}^{R_2} E(r)\,dr$ and the capacitance equals is expressed as

$$C = \frac{2\pi\varepsilon_0\varepsilon l}{\ln(R_2/R_1)}.$$

► **Compound capacitors.** By connecting plates of several simple capacitors, one obtains a *compound capacitor*. The capacitance of a compound capacitor is determined by (P3.4.2.1) and is expressed in terms of the capacitances of its constituents.

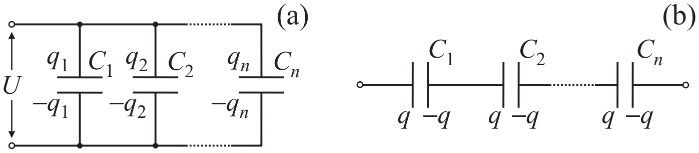

Figure P3.9. Parallel (a) and series (b) connection of capacitors.

1. *Parallel connection*. If n capacitors are connected in parallel with one another as shown in Fig. P3.9(a), they form a compound capacitor for which

$$U = U_i, \quad q = \sum_{i=1}^{n} q_i, \quad C = \sum_{i=1}^{n} C_i.$$

The voltage of all capacitors is the same.

2. *Series connection*. If n capacitors are connected in series as shown in Fig. P3.9(b), they form a compound capacitor for which

$$q = q_i, \quad U = \sum_{i=1}^{n} U_i, \quad \frac{1}{C} = \sum_{i=1}^{n} \frac{1}{C_i}.$$

The total charge at each pair of inner plates is zero.

3. The capacitance of a compound capacitor can often be found by replacing groups of capacitors connected in series or in parallel by an equivalent capacitor, eventually reducing the circuit to a series or parallel one. If the circuit cannot be reduced in this manner, the method of nodal potentials may be applied.

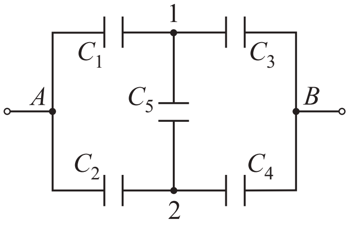

Figure P3.10. A capacitor connection irreducible to a serial or parallel circuit.

Example 4. Consider the circuit shown in Fig. P3.10. Let us take $\varphi_A = 0$. Then $\varphi_B = U$. The three connected plates of the capacitors C_1, C_3, and C_5 must have the same potential, φ_1, and their total charge is zero. The same holds for the capacitors C_2, C_4, and C_5. This allows us to write a system of equations for the potentials φ_1 and φ_2:

$$(\varphi_1 - U)C_3 + (\varphi_1 - \varphi_2)C_5 + \varphi_1 C_1 = 0,$$
$$(\varphi_2 - U)C_4 + (\varphi_2 - \varphi_1)C_5 + \varphi_2 C_2 = 0.$$

Solving the system, we find the charge of the compound capacitor, $q = C_1\varphi_1 + C_2\varphi_2$, and its capacitance $C = q/U$.

P3.5. Electrostatics of Dielectrics

P3.5.1. Polarization of Dielectrics

► **Bound charges. Polarization density.** A dielectric is a material that does not conduct electric current and, hence, has no free charges (or their number is negligibly small). Nevertheless, an electric field becomes weaker inside a dielectric. This indicates that some macroscopic charges arise in the volume and on the surface of a dielectric when placed in an electric field. These charges are due to *polarization* of the dielectric—the phenomenon where charges bound to individual molecules or the crystal lattice are displaced along the field; these charges are called *bound charges*. The average dipole moment of molecules becomes nonzero, which results in a nonzero dipole moment of any volume of the dielectric. The degree of polarization is characterized by the *polarization density vector*, **P**, which is defined as the net dipole moment of the molecules per unit volume:

$$\mathbf{P} = \frac{\sum_i \mathbf{p}_i}{\Delta V} = n\langle \mathbf{p} \rangle,$$

where n is the molecule concentration.

Macroscopic equations of the electric field in a dielectric can be derived using the simplified assumption that all molecules in the small volume ΔV have the same dipole moment $\langle \mathbf{p}\rangle = \mathbf{P}/n = q_0\langle \mathbf{l}\rangle$.

► **Formation of macroscopic bounded charges.** Macroscopic charges distributed over surface and volume can be used to describe the electric field produced by a huge number of oriented microscopic dipoles. The situation where polarization is uniform ($\mathbf{P} = \text{const}$) is easiest to study. In this case, the volume of the dielectric remain electrically neutral and positive surface charges arise on one side of the dielectric and negative surface charges arise on the other side. The vector **P** is directed from the negative to positive charges and the electric field produced will be in *opposite* direction.

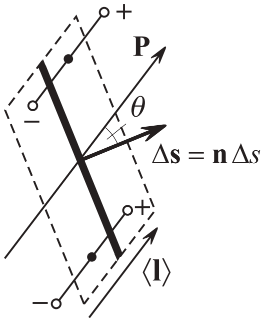

Figure P3.11. Some charges cross a selected area when the dielectric is polarized.

Polarized molecules in the volume of a dielectric are displaced from their original positions so that some charge, Δq, crosses an arbitrary area Δs in the perpendicular direction. This charge equals

$$\Delta q = n(\Delta s\langle l\rangle \cos\theta)q_0 = P_n\Delta s = (\mathbf{P}\cdot\Delta\mathbf{s}) \qquad \text{(P3.5.1.1)}$$

where $\Delta s\langle\, l\,\rangle\cos\theta$ is the volume of a thin cylindrical layer whose molecules cross the area (Fig. P3.11). Integrating over any closed surface yields the net bound charge displaced from the enclosed volume (the net bound charge enclosed within the surface will have the opposite sign):

$$q^{\rm b}_{\rm enc} = -\oint \mathbf{P}\cdot d\mathbf{s} \quad \text{or} \quad \operatorname{div}\mathbf{P} = -\rho^{\rm b}, \tag{P3.5.1.2}$$

where $d\mathbf{s} = \mathbf{n}\,ds$ is the surface element vector directed along the normal toward the surrounding space and $\rho^{\rm b}$ is the volume density of the bound charge. The surface density of the bound charge of (P3.5.1.1) is given by

$$\sigma^{\rm b} = P_n. \tag{P3.5.1.3}$$

► **Electric displacement.** The macroscopic electric field, $\mathbf{E}(\mathbf{r})$, in a polarized dielectric is determined by averaging the microscopic field, $\mathbf{E}_{\rm micro}$ (highly varying at interatomic distances), over a small volume containing sufficiently many molecules: $\mathbf{E}(\mathbf{r}) = \langle \mathbf{E}_{\rm micro}\rangle$. The total electric field is determined by both bound charges and free charges brought to the dielectric from outside:

$$\oint \mathbf{E}\cdot d\mathbf{s} = \frac{1}{\varepsilon_0}(q^{\rm f}_{\rm enc} + q^{\rm b}_{\rm enc}). \tag{P3.5.1.4}$$

Since the bound charge distribution is unknown in advance, it is convenient to introduce a vector quantity

$$\mathbf{D} = \varepsilon_0\mathbf{E} + \mathbf{P}, \tag{P3.5.1.5}$$

which is called the *electric displacement field* or just the *electric displacement*. It follows from equations (P3.5.1.2) and (P3.5.1.4) that the electric displacement is determined by the free charges only:

$$\oint \mathbf{D}\cdot d\mathbf{s} = q^{\rm f}_{\rm enc}. \tag{P3.5.1.6}$$

This equation is known as *Gauss's law for the electric displacement*. In differential form, this law reads

$$\operatorname{div}\mathbf{D} = \rho^{\rm f}.$$

► **Isotropic dielectric.** The polarization density $\mathbf{P}$ at a given point in a dielectric is determined by the external electric field $\mathbf{E}$. For not too strong fields, $\mathbf{P}$ is linearly dependent on $\mathbf{E}$. Furthermore, $\mathbf{P} \parallel \mathbf{E}$ in an *isotropic* dielectric, and hence

$$\mathbf{P} = \varepsilon_0\chi\mathbf{E}, \tag{P3.5.1.7}$$

where χ is the *electric susceptibility* of the dielectric material. Then the electric displacement can be expressed as

$$\mathbf{D} = \varepsilon_0\mathbf{E} + \mathbf{P} = \varepsilon_0\mathbf{E} + \varepsilon_0\chi\mathbf{E} = \varepsilon_0\varepsilon\mathbf{E}, \tag{P3.5.1.8}$$

where $\varepsilon = 1 + \chi$ is the *electric permittivity* of the material.

► **Boundary conditions at dielectric interface.** For two dielectric media meeting along a common interface, the following boundary conditions for tangential and normal components hold:

$$E_{1\tau} = E_{2\tau}, \qquad P_{2n} - P_{1n} = -\sigma^{\rm b}, \qquad D_{2n} - D_{1n} = \sigma^{\rm f}. \tag{P3.5.1.9}$$

The normal $\mathbf{n}$ points from medium 1 to medium 2. If there is no free charge at the interface, the normal components of the displacement are equal to each other. The first condition in (P3.5.1.9) results from the potentiality of the field $\mathbf{E}$ (the work along a closed path is zero). The second and third conditions follow from formulas (P3.5.1.2) and (P3.5.1.6), respectively. For an isotropic dielectric, we have

$$E_{1\tau} = E_{2\tau}, \quad \varepsilon_1 E_{1n} = \varepsilon_2 E_{2n}; \qquad D_{1n} = D_{2n}, \quad \frac{D_{1\tau}}{\varepsilon_1} = \frac{D_{2\tau}}{\varepsilon_2}. \tag{P3.5.1.10}$$

It can be seen that the field lines are refracted at the interface between dielectric media. Note that unlike the electric field, the electric displacement lines are continuous at the interface.

► **Calculation of fields in the presence of dielectrics.** Given the distribution of free charges, the field in the whole space is uniquely determined by the equations for **E** and **D** together with the relation between them (P3.5.1.8) and the boundary conditions (P3.5.1.10). The solution has the following important properties:

1. Using equations (P3.5.1.2) and (P3.5.1.6) and the formula $\mathbf{P} = \frac{\varepsilon - 1}{\varepsilon}\mathbf{D}$, which follows from (P3.5.1.7) and (P3.5.1.8), we find for a homogeneous isotropic dielectric that

$$\rho^{\rm b} = -\frac{\varepsilon - 1}{\varepsilon}\rho^{\rm f}. \qquad \text{(P3.5.1.11)}$$

Consequently, surface bound charge only will arise due to polarization in the absence of volume free charge. Note that for an inhomogeneous dielectric, for which ε depends on the coordinates, volume bound charge arises even if there is no volume free charge.

2. If the boundaries of a homogeneous dielectric coincide with equipotential surfaces of the field $\mathbf{E}_0$ produced by free charges in the absence of the dielectric, then the solution

$$\mathbf{E}(\mathbf{r}) = \frac{\mathbf{E}_0(\mathbf{r})}{\varepsilon} \qquad \text{(P3.5.1.12)}$$

satisfies the boundary conditions.

Example 1. Suppose a point charge q is surrounded by a hollow dielectric sphere with inner radius R_1 and outer radius R_2. The field in the cavity and outside the dielectric will remain the same. Inside the dielectric, the field will change so that

$$E = \frac{1}{4\pi\varepsilon_0\varepsilon}\frac{q}{r^2}, \quad P = \varepsilon_0(\varepsilon - 1)E = \frac{\varepsilon - 1}{\varepsilon}\frac{q}{4\pi r^2},$$
$$\sigma_2^{\rm b} = P(R_2) = \frac{\varepsilon - 1}{\varepsilon}\frac{q}{4\pi R_2^2}, \quad \sigma_1^{\rm b} = -\frac{\varepsilon - 1}{\varepsilon}\frac{q}{4\pi R_1^2}.$$

The bound charges at the inner and outer surfaces are equal to each other in magnitude: $q_2^{\rm b} = -q_1^{\rm b} = q\frac{\varepsilon - 1}{\varepsilon}$.

Example 2. Consider a ball made from a homogeneous dielectric and charged uniformly by a free charge with volume density ρ. The field in the absence of the dielectric was found in example 3, Subsection P3.3.2. The field in the dielectric, for $r < R$, will be weaker by a factor of ε:

$$E = \frac{\rho r}{3\varepsilon_0\varepsilon}, \quad P = \varepsilon_0(\varepsilon - 1)E = \frac{\varepsilon - 1}{\varepsilon}\frac{\rho r}{3},$$
$$\sigma^{\rm b} = P(R) = \frac{\varepsilon - 1}{\varepsilon}\frac{\rho R}{3}, \quad \rho^{\rm b} = -\frac{\varepsilon - 1}{\varepsilon}\rho.$$

It is not difficult to verify that $\sigma^{\rm b}4\pi R^2 = -\rho^{\rm b}\frac{4}{3}\pi R^3$, so the total bound charge is zero, as one would expect.

Example 3. A dielectric slab is placed in a field $\mathbf{E}_0$ so that it enters the slab at the right angle. The electric permittivity of the slab varies from ε_1 at one side to ε_2 at the other side. Then we have

$$D = \varepsilon_0 E_0 = \text{const}, \quad E = \frac{E_0}{\varepsilon(x)}, \quad P = D\frac{\varepsilon - 1}{\varepsilon}, \quad \rho^{\rm b} = -\frac{dP}{dx} = -\frac{D}{\varepsilon^2}\frac{d\varepsilon}{dx},$$
$$\sigma_2^{\rm b} = P_2 = D\frac{\varepsilon_2 - 1}{\varepsilon_2}, \quad \sigma_1^{\rm b} = -P_1 = -D\frac{\varepsilon_1 - 1}{\varepsilon_1}.$$

It is easy to verify that the total bound charge is zero.

Example 4. If a homogeneous dielectric ball is placed in a uniform field $\mathbf{E}_0$, the ball will polarize uniformly ($\mathbf{P} = \text{const}$). Indeed, uniform polarization corresponds to two uniformly charged balls whose centers are displaced by a small vector $\mathbf{l}$, as was shown in example 2, Subsection P3.4.1. The induced polarization field inside the balls is $\mathbf{E}_1 = -\rho\mathbf{l}/3\varepsilon_0 = -(q\mathbf{l}/V)/3\varepsilon_0 = -\mathbf{P}/3\varepsilon_0$. Then the total field in the dielectric is $\mathbf{E} = \mathbf{E}_0 + \mathbf{E}_1 = \mathbf{E}_0 - \mathbf{P}/3\varepsilon_0$. From this equation and the condition $\mathbf{P} = (\varepsilon - 1)\varepsilon_0\mathbf{E}$, we find that

$$\mathbf{E} = \frac{3\mathbf{E}_0}{\varepsilon + 2}, \qquad \mathbf{P} = \frac{3\varepsilon_0(\varepsilon - 1)}{\varepsilon + 2}\mathbf{E}_0.$$

The boundary conditions are all satisfied.

P3.5.2. Types of Dielectric and Polarization Mechanisms

There are three main mechanisms of polarization. Accordingly, three basic types of dielectric are distinguished.

► **1. Dipolar polarization in polar dielectrics.** The molecules of a *polar dielectric* (*polar molecules*) have a permanent dipole moment, p_0, in the absence of electric field. Examples of such substances, are water (H_2O), hydrochloric acid (HCl), ammonia (NH_3), etc. Due to thermal motion, all dipoles are oriented chaotically in the absence of electric field, resulting in a zero average dipole moment. If there is an external field $\mathbf{E}$, dipoles tend to orient along the field (see Subsection P3.2.2). The competition between the chaotic thermal motion and the orienting action of the electric field results in an *average dipole moment* $\langle\mathbf{p}\rangle$. In a weak field ($p_0E \ll kT$), the average dipole moment is proportional to $\mathbf{E}$ and decreases with increasing temperature.

In gaseous dielectrics, the probability for polar molecules to be oriented along $\mathbf{p}$ is proportional to $\exp(-W_\mathrm{p}/kT)$, where $W_\mathrm{p} = -(\mathbf{p}\cdot\mathbf{E})$, which follows from Boltzmann's distribution (see Subsection P2.5.4). It is apparent that, in an external electric field, the average dipole moment must be directed along $\mathbf{E}$ and proportional to $p_0 f(p_0E/kT)$, where $f(x)$ is some function such that $f(0) = 0$ and $f(x) \to 1$ as $x \to \infty$. The case $f(x) \to 1$ corresponds to a strong field, where all dipoles are nearly parallel to $\mathbf{E}$. For small x (a weak field), we have $f(x) \approx \gamma x$ and $\langle\mathbf{p}\rangle \approx \gamma(p_0^2/kT)\,\mathbf{E}$, so the average dipole moment is proportional to $\mathbf{E}$ and inversely proportional to T. The analysis gives $\gamma = 1/3$. Then, $\mathbf{P} = \frac{1}{3}(np_0^2/kT)\,\mathbf{E}$, and hence the electric permittivity evaluates to

$$\varepsilon = 1 + \frac{1}{3}\frac{np_0^2}{\varepsilon_0 kT}.$$

This formula is known as the *Langevin–Debye law*.

► **2. Electronic polarization in nonpolar dielectrics.** In the absence of external electric fields, the dipole moment of a *nonpolar molecule* (e.g., H_2, O_2, N_2, etc.) is zero. So the minimum potential energy corresponds to the state where the center of the negative charge (electronic cloud) of the molecule coincides with that of the positive charge. In the presence of an electric field, the centers of the negative and positive charges are displaced and a force arises that tries to return them to an equilibrium. If the displacement, $\mathbf{l}$, is small, the restoring force is proportional to it: $\mathbf{F} = -\beta\mathbf{l}$ (*quasielastic force*). In equilibrium, $q\mathbf{E} = \beta\mathbf{l}$ and the *induced* dipole moment, $\mathbf{p} = q_0\mathbf{l}$, turns out to be proportional to the field: $\mathbf{p} = \alpha\varepsilon_0\mathbf{E}$. The coefficient α here is called the *molecular polarizability*. The polarization density is $\mathbf{P} = n\mathbf{p} = n\varepsilon_0\alpha\mathbf{E}$, where $\mathbf{E}$ is the field acting on a single molecule. In gases, this field can be regarded as the average field in the dielectric. Consequently, the electric permittivity evaluates to

$$\varepsilon = 1 + \chi = 1 + \alpha n.$$

In dense gases as well as liquid and solid dielectrics, one should take into account that the field acting on a molecule is different from the average field. The molecular field includes the local field produced by the molecule itself, whereas the average field does not.

► **Difference between the local and average fields.** Consider a homogeneous dielectric crystal with nonpolar molecules. In order to find the field acting on a given molecule, consider a sphere with its center at the molecule. If the molecules are arranged in a regular manner (e.g., at the vertices of a cubic lattice), the field produced by the molecules included within the sphere is zero at the center. Hence, the local field at a given point is $\mathbf{E}_\mathrm{loc} = \mathbf{E} + \mathbf{E}_1$, where $\mathbf{E}$ is the average macroscopic field (equal to the sum of the external field and the outer surface charge field) and $\mathbf{E}_1$ is the inner surface charge field of the spherical hollow. As follows from example 4 above, $\mathbf{E}_1 = \mathbf{P}/3\varepsilon_0$, and hence $\mathbf{P} = n\varepsilon_0\alpha\bigl(\mathbf{E} + \frac{1}{3\varepsilon_0}\mathbf{P}\bigr)$, whence

$$\mathbf{P} = \frac{\varepsilon_0 n\alpha\mathbf{E}}{1 - \frac{n\alpha}{3}}.$$

Taking into account that $\mathbf{P} = \varepsilon_0(\varepsilon - 1)\mathbf{E}$, we get

$$\varepsilon - 1 = \frac{n\alpha}{1 - \frac{n\alpha}{3}} \qquad \text{or} \qquad \frac{\varepsilon - 1}{\varepsilon + 2} = \frac{n\alpha}{3}.$$

This result is known as the *Clausius–Mossotti relation*.

► **3. Ionic polarization in solid crystal dielectrics.** Examples of such dielectrics are NaCl, KCl, NaF, KI, etc. In the presence of an external electric field, the sublattice of positive ions (e.g., Na^+) is shifted, as a whole, along the field and the sublattice of negative ions (e.g., Cl^-) is displaced in the opposite direction.

► **Ferroelectrics.** Ferroelectric materials are substances that contain small regions (domains) where all dipoles are spontaneously polarized in the same direction. Ferroelectrics demonstrate this property only below a certain phase transition temperature, T_c, called the *Curie temperature*. These materials are electric analogues of ferromagnetic materials. They have anomalously large electric permittivity, dependent on the electric field and temperature, demonstrate hysteresis properties when polarized, and become usual dielectrics above the Curie temperature. (For details about ferromagnetics, see Subsection P3.9.2.)

P3.6. Energy of Electrostatic Field

P3.6.1. Energy of a System of Charges

► **Potential energy of interaction of charged particles.** The energy of interparticle interaction in a system of charged particles is defined as the work done by external forces to create this system or as the work done by the electric field to destroy this system. The energy of interaction between two charged particles equals the potential energy of one particle in the field produced by the other:

$$W_{12} = q_1\varphi_2(\mathbf{r}_1) = q_2\varphi_1(\mathbf{r}_2) = k\frac{q_1q_2}{r}.$$

The energy of a system of charged particles is

$$W = \sum_{i>j} W_{ij} = \frac{1}{2}\sum_{i\neq j} W_{ij} = \frac{1}{2}\sum_{i} q_i\varphi(\mathbf{r}_i), \qquad \text{(P3.6.1.1)}$$

where $\mathbf{r}_i$ is the position vector of the ith particle and $\varphi(\mathbf{r}_i)$ is the potential created by all other particles at $\mathbf{r}_i$. For continuously distributed charges with volume density $\rho(\mathbf{r})$ and surface density $\sigma(\mathbf{r})$, the above formula becomes

$$W = \frac{1}{2}\int_V \varphi(\mathbf{r})\rho(\mathbf{r})\,dV + \frac{1}{2}\int_S \varphi(\mathbf{r})\rho(\mathbf{r})\,ds. \qquad \text{(P3.6.1.2)}$$

Although formula (P3.6.1.2) is obtained as a formal generalization of formula (P3.6.1.1), there are essential differences between them. In the latter, $\varphi(\mathbf{r}_i)$ is the potential produced by all charges but the ith, whereas in the former, $\varphi(\mathbf{r})$ is the potential of *all* the charges at $\mathbf{r}$ (the contribution of a volume or surface element decreases to zero with the element size). However, the most important difference is this. Formula (P3.6.1.1) considers only the energy of interaction and if the point charges are moved far away from one another, the energy of interaction will be negligibly small but there will still remain the fields of individual charges. Unlike this, formula (P3.6.1.2) calculates the *total energy* of a system of continuously distributed charges and if the system is divided into increasingly smaller parts that are moved away to infinity, the total energy of all these parts will tend to zero.

Example 1. Calculate the energy of a uniformly charged ball of radius R with total charge q.
Solution. Substituting the ball field potential (see example 3, Subsection P3.3.2) into (P3.6.1.2) gives

$$W = \frac{1}{2}\int \rho\varphi\,dV = \frac{\rho}{2}\int_0^R \Bigl(-k\frac{qr^2}{2R^3} + \frac{3}{2}k\frac{q}{R}\Bigr)4\pi r^2 dr = \frac{3}{5}k\frac{q^2}{R}.$$

▶ **Energy of an isolated conductor.** All charges are on the surface and have the same potential, which is the potential of the conductor. From (P3.6.1.2) we have

$$W = \frac{q\varphi}{2} = \frac{C\varphi^2}{2} = \frac{q^2}{2C}, \qquad \text{(P3.6.1.3)}$$

where C is the electric capacitance of the conductor (see Subsection P3.4.1). This result can also be obtained by directly calculating the work done by the field to take the whole charge to infinity: $W = \int \varphi(q)\,dq = C\int_0^\varphi \varphi\,d\varphi = \frac{1}{2}C\varphi^2$.

Example 2. The energy of an isolated conducting sphere equals

$$W = \frac{1}{2}q\cdot\frac{q}{4\pi\varepsilon_0 R} = \frac{q^2}{8\pi\varepsilon_0\varepsilon R},$$

where ε is the electric permittivity of the surrounding medium.

▶ **Capacitor energy.** From (P3.6.1.2) we get

$$W = \frac{q\varphi_1}{2} - \frac{q\varphi_2}{2} = \frac{qU}{2} = \frac{CU^2}{2} = \frac{q^2}{2C}. \qquad \text{(P3.6.1.4)}$$

The field in the capacitor can be destroyed by transferring the charge in small portions from one plate to the other. So $W = \int U(q)\,dq = C\int_0^U U\,dU = \frac{1}{2}CU^2$. For example, the energy of a parallel-plate capacitor is

$$W = \frac{\varepsilon_0\varepsilon S}{2b}(Eb)^2 = \frac{\varepsilon_0\varepsilon E^2}{2}Sb. \qquad \text{(P3.6.1.5)}$$

P3.6.2. Energy of an Electrostatic Field

▶ **Energy density of an electric field.** Within a field approach, one should deal with the energy of the field surrounding charged particles rather than the energy of interparticle interaction. The volume energy density of an electric field, $w = dW/dV$, in vacuum is only dependent on the field strength:

$$w = \tfrac{1}{2}\varepsilon_0 E^2. \qquad \text{(P3.6.2.1)}$$

This expression holds for any charge distribution (e.g., it can be obtained by considering the uniform field of a parallel-plate capacitor).

With the field equations (see Subsection P3.3.2), formula (P3.6.1.2) can be rewritten as

$$W = \frac{1}{2}\int \varepsilon_0 E^2\,dV, \qquad \text{(P3.6.2.2)}$$

where the integration is performed over the whole space.

Formulas (P3.6.1.2) and (P3.6.2.2) allow one to calculate the total energy in the whole space only if: (a) there are no point or linear charges and (b) the charges are limited to a finite region of space. However, formula (P3.6.2.2) calculates not only field energy in the whole space but also energy limited to a finite region of space even if the total energy is infinite.

Example 1. When the charged ball energy was calculated (see example 1) using (P3.6.1.2), the integration was performed of the ball volume (since $\rho = 0$ outside the ball). However, formula (P3.6.2.2) reveals that not all of the field energy is stored within the ball:

$$W_1 = \int \frac{1}{2}\varepsilon_0 E^2\,dV = \int_0^R \frac{1}{2}\varepsilon_0\Big(\frac{qr}{4\pi\varepsilon_0 R^3}\Big)^2(4\pi r^2 dr) = \frac{1}{10}k\frac{q^2}{R}.$$

It makes only 1/6 of the total energy while the 5/6 is stored in the surrounding void space:

$$W_2 = \int_R^\infty \frac{1}{2}\varepsilon_0\Big(\frac{q}{4\pi\varepsilon_0 r^2}\Big)^2(4\pi r^2 dr) = \frac{1}{2}k\frac{q^2}{R}.$$

In a dielectric, the energy density is larger by a factor of ε:

$$w = \tfrac{1}{2}\varepsilon_0\varepsilon E^2 = \tfrac{1}{2}ED = \tfrac{1}{2}\varepsilon_0 E^2 + \tfrac{1}{2}\varepsilon_0(\varepsilon - 1)E^2.$$

The first term in the last expression is the field energy in the dielectric itself while the second term, equal to $\frac{1}{2}\mathbf{E}\cdot\mathbf{P}$, is the work done by the field to polarize the dielectric. This expression can be generalized to the case where $\mathbf{P}$ (and $\mathbf{D}$) are not proportional to $\mathbf{E}$ (e.g., for ferroelectrics and strong fields). To this end, one should look at the process of charging a parallel-plate capacitor filled with such a dielectric:

$$w = \frac{W}{V} = \frac{1}{V}\int U\,dq = \frac{1}{V}\int (Eb)\,d(DS) = \int_0^D \mathbf{E}\cdot d\mathbf{D}.$$

► **Law of conservation of energy. Force calculation.** To calculate the forces, acting on a charged or polarized body in an electric field, one should look at the process of slow isothermal change of the body position. The work done by external forces together with work done by voltage sources are equal to the change in the field energy. Since the body is in mechanical equilibrium, the work done by external forces equals the work done by the force exerted by the field, taken with the opposite sign.

Example 2. A parallel-plate capacitor charged to a voltage U is filled with a liquid or gaseous dielectric with permittivity ε. Find the force acting on either plate. Also treat the case of a solid dielectric.

Solution. Assume that the capacitor is disconnected from the voltage source. When the distance between the plates is increased by dx, the energy increases by $\frac{1}{2}EDS\,dx$ and the work done is $F\,dx$. Hence, the force of attraction equals $F = \frac{1}{2}EDS = \frac{1}{2}Eq$, where $\frac{1}{2}E$ is the field strength in the dielectric produced by either plate ($E = U/b$). However, if the dielectric is a solid slab, then there is an air gap between the dielectric and either plate. Then the energy increment equals $\frac{1}{2}\varepsilon_0 E_0^2 S\,dx$ and the force is

$$F = \frac{1}{2}\varepsilon_0 E_0^2 S = \frac{1}{2}E_0 DS = \frac{1}{2}qE_0,$$

where $\frac{1}{2}E_0$ is the field strength produced by one plate within the air gap ($E_0 = \varepsilon E = \varepsilon U/b$).

Example 3. Find the force at which a dielectric slab is pulled into the gap between the plates of a parallel-plate capacitor charged to a voltage U (see Fig. P3.12).

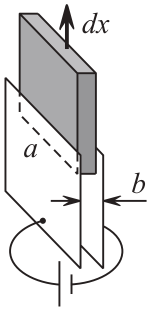

Figure P3.12. To example 3.

Solution. Assume that the respective dimensions of the slab coincide with those of the plates and the slab is slightly thinner than the interplate distance, b. We also assume that the capacitor is connected to a constant voltage source, U. Let us pull the slab out of the capacitor by a distance dx (Fig. P3.12). The field energy within the volume $dV = ab\,dx$ will change by $dW = \left(\frac{1}{2}\varepsilon_0 E^2 - \frac{1}{2}\varepsilon_0\varepsilon E^2\right) ab\,dx$ (a is the slab width and $E = U/b$ is the field). The charge at the plates will change by $dq = \Delta\sigma a\,dx = (\varepsilon_0 E - \varepsilon_0\varepsilon E)a\,dx$ and the work done by the source will be $\delta A_{\text{source}} = U\,dq$, which is twice the field energy increment. Writing the law of conservation of energy, $F\,dx + \delta A_{\text{source}} = dW$, we find that

$$F = \frac{1}{2}\varepsilon_0(\varepsilon - 1)abE^2.$$

Note that this force arises due to field distortion near the plate edges, although the energy calculation was performed without taking into account edge effects.

P3.7. Direct Current

P3.7.1. Electric Current in a Circuit

► **Electric current. Current density.** *Electric current* is an ordered motion of electric charges. *Convection current* is a motion of charges associated with the motion of a charged body. *Conduction current* is a drift motion of *free charges* (*charge carriers*) through a substance (conductor) due to an electric field applied. Examples of free charges are electrons in metals, ions in electrolytes, electrons and ions in plasma, and electrons and "holes" in semiconductors. The positive direction of electric current is conventionally taken to be the direction of positive moving charges.

The charge passing in time dt through an area $d\mathbf{s} = \mathbf{n}\,ds$ inside a conductor in the normal direction $\mathbf{n}$ is determined by the average velocity of free charges, $\langle\mathbf{v}\rangle$:

$$dq = q_0 n\langle\mathbf{v}\rangle\cdot d\mathbf{s}\,dt = \mathbf{j}\cdot\mathbf{s}\,dt, \qquad \text{(P3.7.1.1)}$$

where q_0 is the charge of a single charge carrier, n is the carrier concentration, and $\mathbf{j} = q_0 n\langle\mathbf{v}\rangle$ is the *current density*. The charge passing through the cross-section, S, of a conductor per unit time is called the electric current (or the current) and denoted I:

$$dq = I\,dt = dt\int \mathbf{j}\cdot d\mathbf{s}, \qquad \text{(P3.7.1.2)}$$

where the integration is performed over the cross-section. For a *linear* conductor ($S = \text{const}$), the current density is constant, $\mathbf{j} = \text{const}$, and formula (P3.7.1.2) gives $I = jS$. A current is said to be *constant* if $I = \text{const}$.

The decrease in the total charge within a closed surface equals $dq_{\text{enc}} = -dt \oint \mathbf{j}\cdot d\mathbf{s}$. In differential form, the law of conservation of charge is expressed as $\frac{d\rho}{dt} = -\operatorname{div}\mathbf{j}$. For a constant current, $\oint \mathbf{j}\cdot d\mathbf{s} = 0$, or $\operatorname{div}\mathbf{j} = 0$, so the current flows in continuous lines directed along the conductor.

► **Ohm's law in differential form.** To maintain current through a substance, free charges must be acted upon by an electromagnetic force $\mathbf{F}$, characterized by an electric field $\mathbf{E} = \mathbf{F}/q_0$. As soon as the force is removed, the average velocity of free charges vanishes in a very short time. For not too strong fields, the current density in an isotropic conductor must be proportional to $\mathbf{E}$:

$$\mathbf{j} = \sigma\mathbf{E} = \frac{1}{\rho}\mathbf{E}, \qquad \text{(P3.7.1.3)}$$

where σ is the *conductivity* of the material and ρ is the *resistivity*. It follows from the law of conservation of charge that if $\rho = \text{const}$, then $\oint \mathbf{E}\cdot d\mathbf{s} = \rho\oint \mathbf{j}\cdot d\mathbf{s} = 0$, or $\operatorname{div}\mathbf{E} = 0$. Consequently, the field lines in a *homogeneous conductor* are continuous and in a wire of constant cross-section, they are parallel to the wire surface.

► **Joule–Lenz law in differential form.** As current flows through a conductor, the work done by the field **E** on free charges converts completely into thermal energy due to collisions with ions. The volume density of the thermal power of the current equals the work done by the field on charges per unit time in a unit volume:

$$w_{\text{therm}} = n\langle\mathbf{v}\rangle\cdot\mathbf{F} = q_0 n\langle\mathbf{v}\rangle\cdot\mathbf{E} = \mathbf{j}\cdot\mathbf{E} = \sigma E^2 = \rho j^2. \tag{P3.7.1.4}$$

► **Simple circuit segment. Resistance.** If current flows through a segment of an electrical circuit is due to an electrostatic (Coulomb) field only ($\rho\mathbf{j} = \mathbf{E}_{\text{coulomb}}$), this circuit segment is called *simple*. In a homogeneous conductor ($\rho = \text{const}$), $\oint\mathbf{E}\cdot d\mathbf{s} = \rho\oint\mathbf{j}\cdot d\mathbf{s} = 0$, and, according to Gauss's theorem (see Section P3.3), the field producing charge is only on the surface. In a wire of constant cross-section, the equipotential surfaces coincide with wire cross-sections. The current from a section 1 to section 2 is proportional to the potential difference $\varphi_1 - \varphi_2$:

$$\int_1^2 \mathbf{E}_{\text{coulomb}}\cdot d\mathbf{l} = \int_1^2 \rho\mathbf{j}\cdot d\mathbf{l} = I\int_1^2 \rho\frac{dl}{S} \quad\Longrightarrow\quad \varphi_1 - \varphi_2 = IR. \tag{P3.7.1.5}$$

This result is known as *Ohm's law for a simple circuit segment*. If $I < 0$, then current flows from section 2 to 1. The quantity $R = \int_1^2(\rho/S)\,dl$ is the *electrical resistance of the conductor*. The SI unit of electrical resistance is the ohm (denoted Ω).

For a homogeneous linear conductor, $R = \rho l/S$, where ρ is the electrical resistivity, l is the conductor length, and S is the cross-sectional area. The electrical resistivity is temperature dependent; this dependence is practically linear in a wide range of temperatures: $\rho = \rho_0[1 + \alpha(T - T_0)]$, where ρ_0 is the resistivity at the reference temperature T_0 (e.g., 0° C), α is the *temperature coefficient of resistivity*. For many metals, $\alpha \approx 1/273$ (so $\rho \approx \rho_0\alpha T$); for semiconductors, $\alpha < 0$.

► **Electromotive force.** Although electrostatic forces can maintain current through an open circuit segment, the total work done by these forces around a closed circuit is zero. Consequently, other, nonelectrostatic forces must be present in a closed circuit to compensate for thermal losses; the total work of these forces around a closed circuit is nonzero, and hence these are nonconservative. However, these forces are of electromagnetic nature, $\mathbf{F}_{\text{noncons}} = q_0\mathbf{E}_{\text{noncons}}$, and their work done to transfer a test charge q from point 1 to point 2 is proportional to q:

$$A_q(1\to 2) = q\int_1^2 \mathbf{E}_{\text{noncons}}\cdot d\mathbf{l} = q\mathscr{E}_{12} = \pm q\mathscr{E}, \tag{P3.7.1.6}$$

where $\mathscr{E}$ is the so-called *electromotive force* (or *emf* for short), which has the dimension of voltage and is measured in volts (V). A source of electromotive force is usually regarded as a source of current (such as a battery) and denoted in circuit diagrams by a circle with the minus and plus signs as shown in Fig. P3.13. The plus sign in formula (P3.7.1.6) is taken when the nonconservative forces act in the direction from point 1 to point 2, and the minus sign is taken otherwise. The power of the nonconservative forces (the power of the emf source) equals

$$P_{\text{noncons}} = \frac{A_q(1\to 2)}{t} = I\mathscr{E}_{12}. \tag{P3.7.1.7}$$

The work done by the nonconservative forces in time dt on all charges in the conductor equals the work done to transfer the charge $I\,dt$ from one end of the conductor to the other.

$\mathscr{E}$
2
− +
$\mathscr{E}_{12} = \mathscr{E}$

Figure P3.13. Sign rule for an emf (voltage) source.

► **Ohm's law for a circuit with a current source.** In a circuit containing a source of current, there are both electrostatic and nonelectrostatic forces acting on charges. In this case, Ohm's law in differential form (P3.7.1.3) reads

$$\mathbf{j} = \frac{1}{\rho}(\mathbf{E}_{\text{coulomb}} + \mathbf{E}_{\text{noncons}}), \tag{P3.7.1.8}$$

Ohm's law in integral form becomes

$$I\int_1^2 \rho\frac{dl}{S} = \int_1^2 (\mathbf{E}_{\text{coulomb}} + \mathbf{E}_{\text{noncons}})\cdot d\mathbf{l} \quad\Longrightarrow\quad IR = (\varphi_1 - \varphi_2) + \mathscr{E}_{12}. \tag{P3.7.1.9}$$

If $I < 0$, current flows from 2 to 1. The quantity $U_{12} = (\varphi_1 - \varphi_2) + \mathscr{E}_{12}$, equal to the work done by all forces to transfer a unit charge from cross-section 1 to 2, is called the *voltage* on the selected segment of the circuit. For a simple segment, the voltage equals the potential difference. Thus, Ohm's law states that $IR = U_{12}$ on any circuit segment.

► **Joule–Lenz law for a circuit segment.** The thermal power of electric current on a circuit segment can be found using formula (P3.7.1.4):

$$P_{\text{therm}} = \int_1^2 wS\,dl = \int_1^2 \rho j^2 S\,dl = I^2\int_1^2 \rho\frac{dl}{S} = I^2R. \tag{P3.7.1.10}$$

P3.7.2. Current in a Closed Circuit

► **Ohm's law for an unbranched circuit.** The current through an unbranched closed circuit is constant, $I = \text{const}$. Adding up equations (P3.7.1.9) for all circuit segments, we get

$$I\sum R_i = \sum \mathscr{E}_{ij}. \tag{P3.7.2.1}$$

For example, if the current source has internal resistance r and the resistance of the remaining circuit is R, we have $I = \mathscr{E}/(R + r)$. The potential difference at the source terminals is $\varphi_+ - \varphi_- = IR = \mathscr{E} - Ir$. The short circuit current of the source ($R = 0$) equals $I_{\text{sc}} = \mathscr{E}/r$. Ohm's law (P3.7.2.1) expresses the law of conservation of energy for an unbranched closed circuit: the power of nonconservative forces equals the power of thermal losses at the resistors in the circuit.

► **Useful power of a current source.** If a current source is used to transmit energy into an external circuit, then the total (spent) power equals the power on nonconservative forces: $P_{\text{total}} = \mathscr{E}I$. The lost power equals the thermal losses at the internal resistance: $P_{\text{lost}} = I^2r$. Then the useful power is $P_{\text{useful}} = \mathscr{E}I - I^2r = I\Delta\varphi$, where $\Delta\varphi$ is the potential difference at the source terminals. It can be seen that the maximum of P_{useful} is attained at $I = \mathscr{E}/(2r)$ and is equal to $P_{\max} = \mathscr{E}^2/(4r)$.

If the potential difference supplied at the ends of a circuit segment is $\varphi_1 - \varphi_2$ and the segment contains a device that performs work against the external forces (e.g., an electric motor), then the total power is $P_{\text{total}} = (\varphi_1 - \varphi_2)I$ and the lost power is $P_{\text{lost}} = I^2R$, where R is the resistance of the motor winding. Hence, the useful power equals $P_{\text{useful}} = (\varphi_1 - \varphi_2)I - I^2R = -\mathscr{E}_{12}I = \mathscr{E}I$. The quantities $\mathscr{E}$ and I depend on the revolution speed of the rotor and the maximum of P_{useful} is attained at $I = (\varphi_1 - \varphi_2)/(2R)$.

► **Analysis of branched circuits. Kirchhoff's circuit laws.** In order to determine the currents at various segments of a branched circuit, one should assign symbols to the unknown currents and specify the current directions (in a voluntary way). One of the following two methods should be used thereafter:

1. *Node potential method*. For a circuit involving N nodes, the nodal potentials are taken to be the unknowns (one of the potentials is set to zero). The currents are expressed in terms of the potentials using (P3.7.1.9). The law of conservation of charge is written for each of the $N-1$ unknown nodal potentials in the form $\sum_i I_i = 0$ (the algebraic sum of the currents flowing into and out of a node is zero; the summation is performed over all currents involved). Solving the resulting linear system, one finds the unknown potentials φ_i and then calculates the currents.

2. *Kirchhoff's laws*. In this method, the currents are taken to be the unknowns. First, the equation $\sum_i I_i = 0$ (known as *Kirchhoff's current law* or *Kirchhoff's first rule*) is written for $N-1$ nodes. Then, one chooses an arbitrary closed path and traces it (either clockwise or counterclockwise) summing up the equations of the form (P3.7.1.9) for each segment. This results in an equation of the form $\sum_i I_i R_i = \sum_{i,j} \mathscr{E}_{ij}$ (known as *Kirchhoff's voltage law* or *Kirchhoff's second rule*). This procedure is repeated for all independent closed paths to obtain the required number of equations. Finally, the resulting linear system of equations is solved for the unknown currents.

For more details and examples, see Chapter E6.

► **Equivalent resistances and sources.** Several resistances R_i connected with one another can be replaced by a single equivalent resistance R.

1) For resistances connected in series, $R = \sum_i R_i$.

2) For resistances connected in parallel, $R^{-1} = \sum_i R_i^{-1}$.

3) In the general case, the equivalent resistance is calculated by analyzing branched circuits.

Several connected current sources with emf $\mathscr{E}_i$ and internal resistance r_i can be replaced by a single equivalent sources with parameters $\mathscr{E}$ and r.

1) For sources connected in series, $\mathscr{E} = \sum_i \mathscr{E}_i$ and $r = \sum_i r_i$.

2) For sources connected in parallel, $\mathscr{E} = \sum_i \mathscr{E}_i r_i^{-1} \big/ \sum_i r_i^{-1}$ and $r^{-1} = \sum_i r_i^{-1}$.

3) In the general case, the equivalent emf and resistance are calculated by analyzing branched circuits.

P3.7.3. Classical Free-Electron Theory of Metals

► **Basic postulates.** Conduction of metals is explained by the behavior of valence electrons. The free valence electrons are assumed to form an electron gas. In the classical free-electron theory of Drude–Lorentz, the electron gas is considered to be a classical gas whose concentration equals the atomic concentration of the metal and temperature equals the metal temperature. Conduction current is calculated by assuming that the electrons acquire the drift velocity as they freely move without collisions and that they lose this velocity completely at each collision with metal ions. In addition, it is assumed that $|\langle \mathbf{v}\rangle| \ll \langle v\rangle \sim \sqrt{kT}$. The average drift velocity is expressed as $\langle \mathbf{v}\rangle \sim a\tau/2 = e\mathbf{E}\tau/(2m_e)$, where the mean time between collisions τ is expressed in terms of the mean free path and the mean thermal speed: $\tau = \lambda/\langle v\rangle$. Using (P3.7.1.1), we get

$$\mathbf{j} = en\langle \mathbf{v}\rangle = \frac{e^2 n\lambda}{2m_e\langle v\rangle}\mathbf{E} \quad \text{or} \quad \rho = \frac{2m_e\langle v\rangle}{e^2 n\lambda}.$$

A thorough analysis leads to the same result except that the 2 is absent from the numerator; however, this is not essential for estimates.

► **Discussion of the result of the classical free-electron theory.**

1. The theory explains the increase of ρ with temperature but predicts the behavior $\rho \sim \sqrt{T}$, which is different from the observed relationship $\rho \sim T$.

2. The theory successfully explains the *Wiedemann–Franz law*: for all metals, the product of the thermal conductivity κ (see Subsection P2.9.2) by the electric resistivity ρ is proportional to temperature T (the product $\kappa\rho$ contains $\langle v\rangle^2$ only).

3. The mean free path of electrons predicted by the classical theory is several orders of magnitude larger than the interatomic distance, which contradicts the basic postulates.

4. The electron contribution to the molar heat capacity (see Subsection P2.5.2) is predicted to be $\frac{3}{2}R$. However, the experimentally found contribution is negligibly small.

P3.8. Constant Magnetic Field

P3.8.1. Lorentz Force and Ampère Force

► **Magnetic field. Lorentz force.** Magnetic field is one of the two components of the electromagnetic field (see Subsection P3.2.1). It acts on moving charged particles, currents, and magnetic moments. The sources of magnetic field are moving charged particles, currents, magnetic moments, and changing electric field. A magnetic field is characterized by a vector quantity **B** called the *magnetic induction* (also called the *magnetic field* or *magnetic flux density*). The vector **B** is determined by the equation expressing the force acting on a moving charged particle in an electromagnetic field:

$$\mathbf{F} = q\mathbf{E} + q\mathbf{v}\times\mathbf{B}. \qquad \text{(P3.8.1.1)}$$

The force $\mathbf{F}_\mathrm{L} = q\mathbf{v}\times\mathbf{B}$ exerted by the magnetic field on a moving charged particle is called the *Lorentz force*. (The electromagnetic force **F** is sometimes also called the Lorentz force or *generalized Lorentz force*.) The Lorentz force perpendicular to the particle velocity and, hence, does not produce work.

In order to determine the magnetic induction **B** by formula (P3.8.1.1), one should do the following:

1) measure the force acting on a static particle to isolate the action of the electric field;

2) find the direction of the velocity **v** for which the magnitude of the magnetic force is maximum at constant v;

3) calculate the magnitude of the magnetic induction as $B = F_\mathrm{max}/(qv)$;

4) for known $\mathbf{F}_\mathrm{max}$ and **v**, find the direction of **B** by the right-hand rule.

The magnetic induction can also be determined by the moment of force the magnetic field acts on a small loop of electric current. The electric field does not affect the electric current loop.

The SI unit of magnetic induction is the *tesla* (T): $1\,\mathrm{T} = 1\,\mathrm{N/(A\,m)} = 1\,\mathrm{kg/(A\,s^2)}$.

Example 1. The Hall effect. A conductor with a current flowing through it is immersed in a transverse constant magnetic field (perpendicular to the current). An electrostatic field perpendicular to the magnetic induction arises within the conductor as shown in Fig. P3.14 (the Hall effect). This field results from displacement of the drifting free charges by the action of the Lorentz force. The displacement continues until the Lorentz force is equalized by the electric force: $q_0\langle\mathbf{v}\rangle\times\mathbf{B} = -q_0\mathbf{E}$. Multiplying by the concentration of free charges, n, we express **E** in terms of the current density to obtain $\mathbf{E} = -\frac{1}{q_0 n}\mathbf{j}\times\mathbf{B}$. It can be seen that the free charge concentration (for charges of the same type) and the sign of the charges can be obtained from the measurement of the magnitude and direction of the electric field **E**.

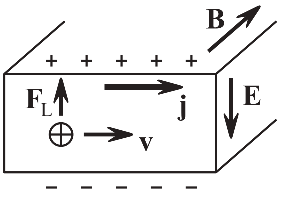

Figure P3.14. A conductor with a current immersed in a magnetic field (the Hall effect).

Example 2. Particle in a uniform magnetic field. Consider a nonrelativistic particle of mass m and charge q moving with a velocity **v** in a uniform magnetic field **B**. Suppose that **v** makes an angle α with **B** at some instant. The Lorentz force is perpendicular to both **v** (hence, v = const) and **B** (hence, the velocity projections $v_{\|}$ and $v_{\perp}$ onto **B** and the plane perpendicular to **B** are conserved). In the projection onto the perpendicular plane, the particle moves in a circle, whose radius can be found from Newton's second law: $qv_{\perp}B = mv_{\perp}^2/R$. The period of revolutions, $T = 2\pi R/v_{\perp} = 2\pi m/qB$, is independent of the speed. So the resulting motion occurs in a helical path with radius R and pitch $h = v_{\|}T = 2\pi mv\cos\alpha/(qB)$.

► **Ampère's law.** The force acting on a current element in a magnetic field (*Ampère's force*) equals the sum of the forces acting on the moving free charges:

$$d\mathbf{F} = q_0[\langle\mathbf{v}\rangle\times\mathbf{B}]\,dN = nq_0[\langle\mathbf{v}\rangle\times\mathbf{B}]\,dV = \mathbf{j}\times\mathbf{B}\,dV = I\,d\mathbf{l}\times\mathbf{B}. \qquad \text{(P3.8.1.2)}$$

This result is known as *Ampère's force law* (in differential form). Note the use of formula (P3.7.1.1), linking the current density to the mean velocity of free charges, to relate the force acting on a volume element dV with current density **j** and a line element $d\mathbf{l}$ with current I. The total force acting of a finite volume with distributed current $\mathbf{j}(\mathbf{r})$ of a linear current-carrying wire is obtained by integrating. For example, the force acting on a wire of length **l** with current I in a uniform magnetic field **B** equals $I\mathbf{l}\times\mathbf{B}$. The force acting on a current-carrying loop is zero: $\mathbf{F} = \oint I\,d\mathbf{l}\times\mathbf{B} = I\bigl(\oint d\mathbf{l}\bigr)\times\mathbf{B} = \mathbf{0}$.

► **Magnetic moment of a current-carrying loop.** The magnetic moment of a wire loop carrying current I is defined as the vector quantity

$$\mathbf{p}_{\rm m} = I\int\mathbf{n}\,ds, \qquad \text{(P3.8.1.3)}$$

where the integration is carried out over any surface spanning the loop and the direction of the normal is determined by the right-hand rule. For a plane loop, we have

$$\mathbf{p}_{\rm m} = IS\mathbf{n} = I\mathbf{S}.$$

The magnetic moment of a loop is a magnetic analogue of the electric dipole moment (see Subsections P3.1.1 and P3.2.2); it determines the magnetic field of the loop at large distances from it and characterizes the behavior of the loop in a magnetic field.

Example 3. Consider a rectangular loop with sides a and b, suspended at the side a is a vertical uniform magnetic field **B** (Fig. P3.15). When current I is supplied, the loop will deflect by an angle β such that the moment of the force of gravity is equalized by the moment of the Ampère force: $mg\frac{1}{2}b\sin\beta = IBab\cos\beta$, or $\tan\beta = 2IBa/(mg)$. Note that the torque exerted by the magnetic field on the loop equals $\mathbf{M} = I\mathbf{S}\times\mathbf{B} = \mathbf{p}_{\rm m}\times\mathbf{B}$. A similar expression was obtained for the torque acting on an electric dipole in an electric field (see Subsection P3.2.2).

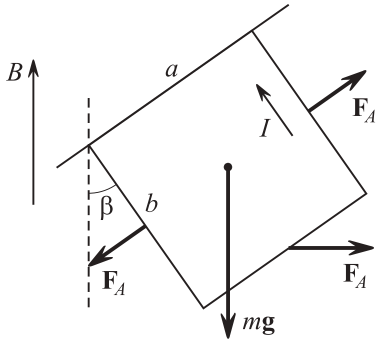

Figure P3.15. A rectangular current-carrying loop in a magnetic electric (to example 3).

P3.8.2. Calculation of Magnetic Induction

► **Biot–Savart–Laplace law.** The magnetic induction created by a current element $I\,d\mathbf{l}$ at a point A equals

$$d\mathbf{B} = \frac{\mu_0}{4\pi}\frac{I\,d\mathbf{l}\times\mathbf{r}}{r^3}, \qquad \text{(P3.8.2.1)}$$

where $\mathbf{r}$ is the radius vector from the current element to the point A and $\mu_0 = 1/(\varepsilon_0 c^2) = 4\pi\times10^{-7}$ T m/A (or H/m) is the magnetic constant. This result is known as the *Biot–Savart law* or the *Biot–Savart–Laplace law*. Equation (P3.8.2.1) can be rewritten for the magnetic induction of a volume current element $\mathbf{j}\,dV$, a surface current element $\mathbf{i}\,ds$, or, on dividing by the number of free current carriers, a nonrelativistic particle $q\mathbf{v}$:

$$d\mathbf{B} = \frac{\mu_0}{4\pi}\frac{\mathbf{j}\times\mathbf{r}}{r^3}dV, \quad d\mathbf{B} = \frac{\mu_0}{4\pi}\frac{\mathbf{i}\times\mathbf{r}}{r^3}ds, \quad d\mathbf{B} = \frac{\mu_0}{4\pi}\frac{q\mathbf{v}\times\mathbf{r}}{r^3}. \qquad \text{(P3.8.2.2)}$$

(The surface density of electric current is the current per unit length of the segment perpendicular to the current: $dI = i\,dl$.) In order to calculate the magnetic induction produced by a finite volume, surface, or wire, one has to perform integration (principle of superposition for magnetic induction).

► **On systems of units in electromagnetism.** Here and henceforth the formulas are given in SI. To convert units to the Gaussian system (CGS), it suffices in most cases to substitute $\mathbf{B}$ by $\mathbf{B}/c$ (and the flux Φ by Φ/c) and μ_0 by $4\pi/c^2$. If a formula involves the Coulomb constant k, it must be substituted by 1. The electric constant ε_0 is substituted by $1/(4\pi)$. It is noteworthy that $\mu_0\varepsilon_0 = 1/c^2$.

Example 1. Find the magnetic force acting between two particle of charges q_1 and q_2 having identical velocities, $\mathbf{v}_1 = \mathbf{v}_2 = \mathbf{v}$ ($v \ll c$), at some instant of time with $\mathbf{v}$ being perpendicular to the line connecting the charges.

Solution. The magnitude of the magnetic induction created by the first particle at the point where the second particle is located is $B = \frac{\mu_0}{4\pi}\frac{q_1 v}{r^2}$, where r is the interparticle distance. The field is perpendicular to $\mathbf{v}$ and $\mathbf{r}$. For charges of like sign, the Lorentz force acts in the direction of particle 1 and its magnitude equals $F = \frac{\mu_0}{4\pi}\frac{q_1 q_2 v^2}{r^2}$. The ratio of the magnetic force to the electrostatic force is $\mu_0\varepsilon_0 v^2 = \frac{v^2}{c^2}$.

Example 2. Magnetic field in the center of a circular current. Find the magnetic induction created by a circular loop of radius R at its center. The current flowing through the loop is I.

Solution. The magnetic induction created by an arc element $d\varphi$ equals

$$dB = \frac{\mu_0}{4\pi}\frac{IR\,d\varphi}{R^2} = \frac{\mu_0 I\,d\varphi}{4\pi R}$$

in magnitude and is directed along the axis (the right-hand rule). At its center, the whole loop creates the field

$$B = \frac{\mu_0 I}{2R}.$$

Example 3. Magnetic field at the axis of a circular current. Find the magnetic induction produced by a circular current (of radius R) on its axis at the point A located at a distance y from the loop center (Fig. P3.16).

Solution. The vector $\mathbf{B}$ is directed along the y-axis and the contribution of an arc element $d\varphi$ of the loop equals

$$dB_y = dB\sin\alpha = \frac{\mu_0}{4\pi}\frac{IR\,d\varphi}{R^2+y^2}\frac{R}{\sqrt{R^2+y^2}}.$$

Integrating with respect to φ yields

$$B = \frac{\mu_0 I R^2}{2(R^2+y^2)^{3/2}}.$$

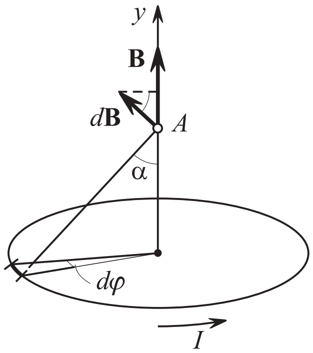

Figure P3.16. Magnetic field at the axis of a circular current.

At large distances from the loop ($y \gg R$), the magnetic induction

$$B \approx \frac{\mu_0 I R^2}{2y^3} = \frac{\mu_0}{4\pi}\frac{2I(\pi R^2)}{y^3}$$

is expressed in terms of the magnetic moment $\mathbf{p}_\mathrm{m} = I\mathbf{S}$ in a similar manner as the electric field strength is expressed via the electric dipole moment (see example 4, Subsection P3.2.2, the case $\mathbf{r} \parallel \mathbf{p}$). I can be shown that at an arbitrary point $\mathbf{r}$, the magnetic induction of a small plane current-carrying loop equals

$$\mathbf{B} = \frac{\mu_0}{4\pi r^3}\left(\frac{3\mathbf{p}_\mathrm{m}\cdot\mathbf{r}}{r^2}\mathbf{r} - \mathbf{p}_\mathrm{m}\right). \qquad \text{(P3.8.2.3)}$$

Example 4. Magnetic field of a linear current segment. Find the magnetic induction produced by a linear wire segment at the point A whose location is determined by its distance y to the straight line of the segment and two angles α_1 and α_2 as shown in Fig. P3.17.

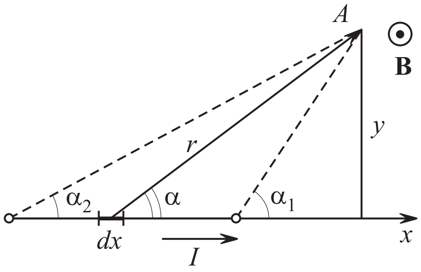

Figure P3.17. Magnetic field of a linear current segment.

Solution. The contribution of the element dx equals $dB = \frac{\mu_0}{4\pi}\frac{I\,dx}{r^2}\sin\alpha$; the field is perpendicular to the plane through the segment and the point A. It is convenient to integrate with respect to the angle α. Substituting $r = y/\sin\alpha$, changing the variable $x = -y\cot\alpha$, $dx = y\,d\alpha/\sin^2\alpha$, and integrating, we obtain

$$B = \frac{\mu_0 I}{4\pi y}(\cos\alpha_1 - \cos\alpha_2). \qquad \text{(P3.8.2.4)}$$

Setting $\alpha_1 = 0$ and $\alpha_2 = \pi$, we find the magnetic induction of an infinitely long straight current-carrying wire:

$$B = \frac{\mu_0 I}{2\pi y}. \qquad \text{(P3.8.2.5)}$$

Let us use (P3.8.2.4) to calculate the magnetic induction at the center of a rectangular loop to obtain

$$B = \frac{\mu_0}{4\pi}\frac{8I\sqrt{a^2+b^2}}{ab},$$

where a and b are the sides of the rectangle.

P3.8.3. Ampère's Circuital Law and Flux of Magnetic Induction

► **Ampère's circuital law.** From the Biot–Savart–Laplace law it can be inferred that the *circulation of magnetic induction* around any closed path is determined by the algebraic sum of the currents enclosed by the path (i.e., by the current passing through a surface spanning the path):

$$\oint \mathbf{B}\cdot d\mathbf{l} = \mu_0 I_{\text{enc}} = \mu_0 \int \mathbf{j}\cdot d\mathbf{s}. \qquad \text{(P3.8.3.1)}$$

The positive direction of the surface normal is determined by the right-hand rule.

► **Gauss's law for magnetism.** The *flux of magnetic induction* (*magnetic flux*) through any closed surface is zero:

$$\oint \mathbf{B}\cdot d\mathbf{s} = 0. \qquad \text{(P3.8.3.2)}$$

This means the magnetic field lines are everywhere continuous, or there are no *magnetic charges*, at which magnetic field lines would start or terminate.

The magnetic flux through any surface S is defined as

$$\Phi = \int_S \mathbf{B}\cdot d\mathbf{s}.$$

The SI unit of magnetic flux is the *weber* (Wb), with $1\,\text{Wb} = 1\,\text{T}\,\text{m}^2$. It is noteworthy that magnetic flux through a surface spanning a closed path does not depend on the shape of the surface. Therefore, it is meaningful to speak about magnetic flux through a closed path.

Example 1. Magnetic field of a solenoid. A solenoid is a helical coil formed by a long thin wire densely wound on a cylinder. A solenoid is characterized by the number of turns per unit length, n. The ideal model of a solenoid is an infinitely long thin cylindrical surface carrying current $i = nI$, with the current perpendicular to the axis. It is not difficult to verify that the magnetic field inside an ideal solenoid is everywhere parallel to the axis (to this end, one should consider the contributions of any two symmetric current elements). There is no magnetic field outside the solenoid. It follows from Ampère's circuital law and Gauss's law that $\mathbf{B} = \text{const}$ inside the solenoid. In order to find the magnitude B, one should apply Ampère's circuital law to a rectangular loop one side of which is inside the solenoid and parallel to its axis and the opposite side is outside as shown in Fig. P3.18. One finds that $Bl = \mu_0 il$. So the magnetic field inside the solenoid is

$$B = \mu_0 i = \mu_0 nI. \qquad \text{(P3.8.3.3)}$$

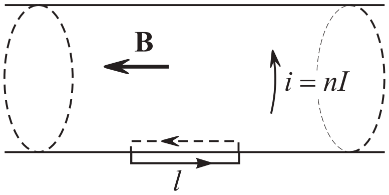

Figure P3.18. The magnetic field inside a solenoid can be found using Ampère's circuital law.

Example 2. Magnetic field of a rod. Find the magnetic field of an infinitely long straight rod of radius R carrying current I (Fig. P3.19). The magnetic lines are circles. Choose a circle of radius r as the closed path for Ampère's circuital law (P3.8.3.1). For $r > R$, we get $B \times 2\pi r = \mu_0 I$. For $r < R$, we find that $B \times 2\pi r = \mu_0 I(\pi r^2/\pi R^2)$. Hence,

$$B = \begin{cases} \dfrac{\mu_0 I}{2\pi r} & \text{for } r > R, \\ \dfrac{\mu_0 I r}{2\pi R^2} & \text{for } r < R. \end{cases}$$

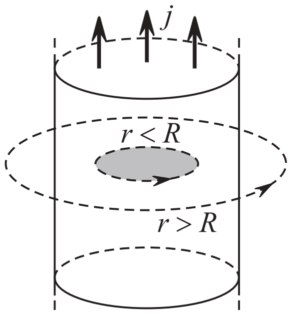

Figure P3.19. Magnetic field of a rod.

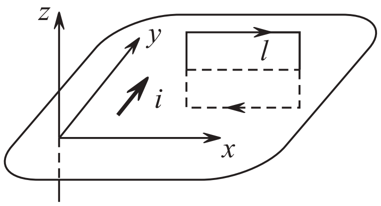

Figure P3.20. Magnetic field of a current plane.

Example 3. Magnetic field of a current plane. Consider an infinite plane (x, y) carrying current in the y-direction with a constant density i. The magnetic field above the plane, $z > 0$, is directed in the positive x-direction and that below the plane, $z < 0$, is in the negative x-direction (this can be verified by considering the contributions of two infinite straight currents symmetric relative to the point of interest). Choose a rectangular path with one side above the plane and in the x-direction and the other being symmetrically located below the plane (Fig. P3.20). Ampère's circuital law gives $2Bl = \mu_0 il$, and hence $B = \frac{1}{2}\mu_0 i$.

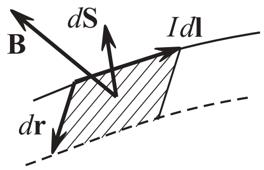

Figure P3.21. Displacement of a current loop element in a magnetic field.

► **Displacement of a current loop in a magnetic field.** When a loop carrying constant current I is moved or deformed in a constant magnetic field, the Ampère force performs work. The elementary work done by the Ampère force acting on a loop element equals

$$\delta A = d\mathbf{F} \cdot d\mathbf{r} = I[d\mathbf{l} \times \mathbf{B}] \cdot d\mathbf{r} = I\mathbf{B} \cdot [d\mathbf{r} \times d\mathbf{l}] = I\mathbf{B} \cdot d\mathbf{s},$$

where $d\mathbf{r}$ is the displacement of the loop element $d\mathbf{l}$, $d\mathbf{s}$ is the area element swept out by $d\mathbf{l}$ (Fig. P3.21). Integrating around the loop yields the elementary mechanical work done by the magnetic field in terms of the increment in the magnetic flux Φ through the loop:

$$\delta A_{\text{mech}} = I\,d\Phi. \qquad \text{(P3.8.3.4)}$$

It follows that a *potential function*, $W_{\text{p}} = -I\Phi$, can be associated with a loop carrying current I in a constant magnetic field. A change in this function equals (with the opposite sign) the work done by the Ampère force:

$$A_{\text{mech}} = -\Delta W_{\text{p}}, \qquad W_{\text{p}} = -I\Phi. \qquad \text{(P3.8.3.5)}$$

For a uniform field or a small plane loop, formula (P3.8.3.5) becomes

$$W_{\text{p}} = -\mathbf{p}_{\text{m}} \cdot \mathbf{B}, \qquad \text{(P3.8.3.6)}$$

where $\mathbf{p}_{\text{m}}$ is the magnetic moment of the current loop (see Subsection P3.8.1). Since this expression coincides with the potential energy of an electric dipole (see Subsection P3.2.2), it is natural to assume that the torque acting on a magnetic dipole and the force acting on a magnetic dipole in a nonuniform field should have the same form:

$$\mathbf{M} = \mathbf{p}_{\text{m}} \times \mathbf{B}, \qquad \mathbf{F} = p_{\text{m}} \frac{\partial \mathbf{B}}{\partial n} = p_{\text{m}x} \frac{\partial \mathbf{B}}{\partial x} + p_{\text{m}y} \frac{\partial \mathbf{B}}{\partial y} + p_{\text{m}z} \frac{\partial \mathbf{B}}{\partial z}, \qquad \text{(P3.8.3.7)}$$

where $\mathbf{n}$ is parallel $\mathbf{p}_{\text{m}}$. The equilibrium orientation of a magnetic dipole corresponds to the minimum potential energy, and hence it corresponds to $\mathbf{p}_{\text{m}} \parallel \mathbf{B}$. A current loop oriented in this manner is pulled into the region of a stronger magnetic field.

▶ **Maxwell's equations for a constant magnetic field.** In differential form, these equations are

$$\operatorname{curl}\mathbf{B} = \mu_0\mathbf{j}, \qquad \operatorname{div}\mathbf{B} = 0.$$

In integral form, these are equations (P3.8.3.1) and (P3.8.3.2).

▶ **Vector potential.** Maxwell's equation $\operatorname{div}\mathbf{B} = 0$ is satisfied if the magnetic field is sought in the form $\mathbf{B} = \operatorname{curl}\mathbf{A}$. The *vector potential* $\mathbf{A}$ is defined up to an arbitrary constant scalar field χ. The potential $\mathbf{A}' = \mathbf{A} + \operatorname{grad}\chi$ generates the same field $\mathbf{B}$ as $\mathbf{A}$; this expression is known as the *calibration transformation for a vector potential*. This transformation allows us to simplify the vector potential equation resulting from substituting $\mathbf{B} = \operatorname{curl}\mathbf{A}$ into the first Maxwell equation: $\operatorname{grad}\operatorname{div}\mathbf{A} - \Delta\mathbf{A} = \mu_0\mathbf{j}$. By choosing a scalar field χ such that $\operatorname{div}\mathbf{A} = 0$, we arrive at the equation

$$\Delta\mathbf{A} = -\mu_0\mathbf{j}.$$

The equation for each projection of $\mathbf{A}$ onto the coordinate axes is mathematically identical with the equation for the electric scalar potential (see Subsection P3.3.2). Consequently, the solution of these equations is given by

$$\mathbf{A}(\mathbf{r}) = \frac{\mu_0}{4\pi}\int\frac{\mathbf{j}(\mathbf{r}')\,dV'}{|\mathbf{r}-\mathbf{r}'|}.$$

In particular, one can find the field of a small current loop (see (P3.8.2.3)) or prove the Biot–Savart law using this expression.

P3.9. Magnetic Field in Matter

P3.9.1. Magnetization. Molecular Currents

▶ **Magnetization of a material.** A material is regarded as magnetized if it creates a magnetic field inside itself and in the surrounding space in the absence of conduction currents. The source of magnetic field of a magnetized material are magnetic moments of atoms and molecules (atomic and molecular currents). In the absence of an external magnetic field, microscopic magnetic moments are either absent (in *diamagnetic* materials) or chaotically oriented (in *paramagnetic* materials). In both cases, the macroscopic magnetic field is zero. Constant magnets (made from *ferromagnetic* substances) are an exception; they can have a macroscopic magnetic field (see below for details). When a material is immersed in an external magnetic field, the material is magnetized and an induced volumetric magnetic moment arises. The degree to which a material is magnetized is characterized by the vector of *magnetization* $\mathbf{J}$, which is defined as the net magnetic moment per unit volume:

$$\mathbf{J} = \frac{\sum_i \mathbf{p}_{\mathrm{m}i}}{\Delta V} = n\langle\mathbf{p}_{\mathrm{m}}\rangle, \tag{P3.9.1.1}$$

where n is the molecule concentration. For the construction of macroscopic field equations for a magnetized material, it can be assumed for simplicity that all molecules in a small volume ΔV have the same magnetic moment $\langle\mathbf{p}_{\mathrm{m}}\rangle = \mathbf{J}/n = I_0\mathbf{s}$, or they can be represented as identical microscopic current loops.

▶ **Macroscopic molecular currents.** In characterizing magnetic field in matter, the huge number of oriented microscopic currents (magnetic moments) may be replaced by macroscopic molecular currents distributed across surface and volume. For a simple example, consider a homogeneous magnetized cylinder whose molecular current loops are all oriented along the cylinder axis. The different currents will compensate for one another inside the cylinder and there will be uncompensated current flowing along the surface. The magnetic

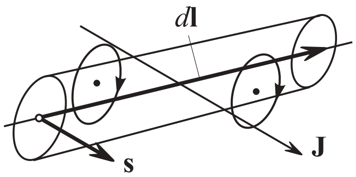

Figure P3.22. Magnetization creates a molecular current piercing the loop.

field of the surface current, $\mathbf{B}_{\text{mol}}$, will have, inside the cylinder, the *same direction* as the magnetization $\mathbf{J}$.

For an arbitrary closed path, its element $d\mathbf{l}$ inside the magnetized material pierces the current loops whose centers fall within the volume $dV = \mathbf{s}\cdot d\mathbf{l}$ (Fig. P3.22). The contribution into the molecular current enclosed by the path (i.e., the current crossing the surface that spans the path) equals $I_0 n\,dV = nI_0\mathbf{s}\cdot d\mathbf{l} = \mathbf{J}\cdot d\mathbf{l}$. Integrating gives

$$\oint \mathbf{J}\cdot d\mathbf{l} = I_{\text{enc}}^{\text{mol}}. \qquad \text{(P3.9.1.2)}$$

In differential form, this equation becomes $\operatorname{curl}\mathbf{J} = \mathbf{j}_{\text{mol}}$. These two equations allow us to express the current density at the surface as

$$\mathbf{i}_{\text{mol}} = \mathbf{J}\times\mathbf{n}, \qquad \text{(P3.9.1.3)}$$

where $\mathbf{n}$ is the outward normal to the surface of the magnetized material.

► **Magnetic field strength.** Macroscopic magnetic induction in a magnetized material results from averaging the microscopic field $\mathbf{B}$, highly varying at interatomic distances, over a small volume, though large enough to contain a large number of molecules: $\mathbf{B}(\mathbf{r}) = \langle\mathbf{B}_{\text{micro}}\rangle$. The magnetic induction is determined by both molecular and nonmolecular currents (such as conduction currents or convection currents):

$$\oint \mathbf{B}\cdot d\mathbf{l} = \mu_0\bigl(I_{\text{enc}}^{\text{nonmol}} + I_{\text{enc}}^{\text{mol}}\bigr). \qquad \text{(P3.9.1.4)}$$

Since the molecular current distribution is usually unknown, it is convenient to introduce a new vector quantity called the *magnetic field strength* and defined as

$$\mathbf{H} = \frac{\mathbf{B}}{\mu_0} - \mathbf{J}, \qquad \text{(P3.9.1.5)}$$

which is only defined by nonmolecular currents:

$$\oint \mathbf{H}\cdot d\mathbf{l} = I_{\text{enc}}^{\text{nonmol}} \qquad \text{(P3.9.1.6)}$$

(Ampère's circuital law for the magnetic field strength). In differential form, this expression becomes: $\operatorname{curl}\mathbf{H} = \mathbf{j}^{\text{nonmol}}$. The SI unit for magnetic field strength is A/m.

► **Boundary conditions at the interface between different magnetic materials.** For the normal and tangential components of $\mathbf{B}$, $\mathbf{H}$, and $\mathbf{J}$, the following boundary conditions hold at the interface between two magnetic media:

$$B_{2n} = B_{1n}, \quad \mathbf{H}_1\times\mathbf{n} - \mathbf{H}_2\times\mathbf{n} = \mathbf{i}_{\text{nonmol}}, \quad \mathbf{J}_1\times\mathbf{n} - \mathbf{J}_2\times\mathbf{n} = \mathbf{i}_{\text{mol}}, \qquad \text{(P3.9.1.7)}$$

where $\mathbf{n}$ is a normal vector pointing from medium 1 to medium 2 and $|\mathbf{H}\times\mathbf{n}| = H_\tau$. If there is no nonmolecular current at the interface, the second condition can be rewritten as $H_{1\tau} = H_{2\tau}$. The first condition follows from Gauss's law (P3.8.3.2) for $\mathbf{B}$, the second follows from (P3.9.1.6), and the third from (P3.9.1.3). There is a formal analogy in boundary conditions between $\mathbf{H}$ and $\mathbf{E}$ and also between $\mathbf{B}$ and $\mathbf{D}$ (see Subsection P3.5.1).

► **Isotropic magnetic material.** The magnetization **J** at a given point inside a magnetic material arises due to an external magnetic field and is determined by the vector **B**. For not too strong fields, **J** depends on **B** linearly and in an *isotropic material*, in addition, $\mathbf{J} \parallel \mathbf{B}$. Then both vectors **J** and **H** are proportional to **B** and to each other. For historical reasons (due to the analogy between **E** and **H** in boundary conditions), the *magnetic susceptibility* is defined by

$$\mathbf{J} = \chi\mathbf{H}, \qquad \mathbf{J} = \frac{\chi}{\mu_0(1+\chi)}\mathbf{B}. \tag{P3.9.1.8}$$

From (P3.9.1.5) we get

$$\mathbf{B} = \mu_0(1+\chi)\mathbf{H} = \mu_0\mu\mathbf{H}, \tag{P3.9.1.9}$$

where μ is the *magnetic permeability* of the material. For paramagnetic materials, $\chi > 0$. For diamagnetic materials, $\chi < 0$. In both cases, $|\chi| \ll 1$ (weak magnetic properties). For ferromagnetic materials, $\chi \gg 1$.

The boundary conditions at the interface between two isotropic magnetic media are

$$B_{1n} = B_{2n}, \quad \frac{B_{1\tau}}{\mu_1} = \frac{B_{2\tau}}{\mu_2}; \qquad \mu_1 H_{1n} = \mu_2 H_{2n}, \quad H_{1\tau} = H_{2\tau}.$$

► **Calculation of fields in the presence of a magnetic material.** The equations for **B** and **H** together with the above boundary conditions determine magnetic field in the whole space if the nonmolecular currents are known. Below are some important properties of solutions:

1. The volume density of the molecular current is proportional to that of the nonmolecular current: $\mathbf{j}^{\text{mol}} = \chi\mathbf{j}^{\text{nonmol}}$. If there are no nonmolecular currents, then surface molecular currents only arise when the material is magnetized.

2. If the boundaries of a homogeneous magnetic material are everywhere tangent to the original ($\mathbf{B}_0$) magnetic lines, then $\mathbf{B} = \mu\mathbf{B}_0$ everywhere in the magnetic material.

Example 1. A long paramagnetic cylinder is immersed in a uniform magnetic field whose induction $\mathbf{B}_0$ is parallel to the cylinder axis. Find the magnetic induction, magnetic field strength, and magnetization inside the cylinder.

Solution. Everywhere inside the cylinder (except for its edges) we have: $\mathbf{B} = \mu\mathbf{B}_0$, $\mathbf{H} = \mathbf{H}_0 = \mathbf{B}_0/\mu_0$, and $\mathbf{J} = (\mu - 1)\mathbf{B}_0/\mu_0$.

Example 2. An infinitely long rod of circular cross-section, made from a material with magnetic permeability $\mu > 1$, carries a constant current with density **j**. Find the magnetic field strength, magnetic induction, and magnetization. Also calculate the surface and volume density of the molecular current.

Solution. The molecular current within the rod volume has the density $\mathbf{j}^{\text{mol}} = (\mu-1)\mathbf{j}$. The field strength H can be found using Ampère's circuital law (P3.9.1.6). We get $H = I/(2\pi r)$ for $r > R$ and $H = Ir/(2\pi R^2)$ for $r < R$ (see example 2, Subsection P3.8.3). The magnetic induction equals $B = \mu_0 H$ for $r > R$ and $B = \mu_0\mu H$ for $r < R$; it has a jump discontinuity at the surface current. The magnetization equals $J = (\mu - 1)Ir/(2\pi R^2)$ ($J = 0$ outside the rod). The magnetic lines are concentric circles and the vectors **H** and **J** are parallel to **B**. The surface molecular current is $\mathbf{i} = \mathbf{J}\times\mathbf{n}$; it equals $i_{\text{mol}} = (\mu - 1)I/(2\pi R)$ in magnitude and is opposite to **j** in direction. The total molecular current is zero, and hence $j_{\text{mol}}\pi R^2 = i_{\text{mol}}2\pi R$.

P3.9.2. Types of Magnetic Materials and Magnetization Mechanisms

Atomic and molecular magnetic moments are created by (a) the motion of electrons in closed orbits (orbital magnetic moments) and (b) the intrinsic magnetic moments of electrons related to the intrinsic mechanical angular momentum—spin (spin magnetic moments). Each type of magnetic moment is proportional to the corresponding mechanical angular momentum: $\mathbf{p}_{\text{m}} = -g(e/2m)\mathbf{L}$, where g is a dimensionless coefficient called the *gyromagnetic ratio*. For orbital moment, $g = 1$. For spin moment, $g = 2$.

► **Diamagnets. Larmor's mechanism of diamagnetic magnetization.** In the absence of external magnetic fields, the magnetic moments of atomic (molecular) electrons in a diamagnetic material (diamagnet) compensate for one another. When a magnetic field is applied, a torque starts to act on each magnetic moment. As a result, the magnetic moment rotates about the magnetic field direction (*Larmor precession*):

$$\frac{d\mathbf{L}}{dt} = \mathbf{p}_\mathrm{m} \times \mathbf{B} = -g\frac{e}{2m}\mathbf{L} \times \mathbf{B} = \left(g\frac{e}{2m}\mathbf{B}\right) \times \mathbf{L}.$$

The vector **L** (and also $\mathbf{p}_\mathrm{m}$) rotates with an angular velocity $\boldsymbol{\omega}_\mathrm{L} = g\frac{e}{2m}\mathbf{B}$ (Fig. P3.23). This rotation gives rise to an additional magnetic moment of each electron, $\Delta\mathbf{p}_\mathrm{m}$, opposing to **B** (independently of the original direction of $\mathbf{p}_\mathrm{m}$).

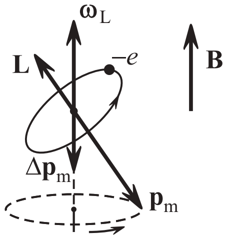

Figure P3.23. Larmor precession in diamagnetic materials.

► **Orientational mechanism of magnetization in paramagnetic materials.** In paramagnets, the magnetic moments of electrons do not compensate for one another even in the absence of external magnetic fields. The weak mechanism of diamagnetic magnetization is superimposed by a stronger orientational mechanism: in the presence of magnetic field, the orientation of the magnetic moment along the field is less costly energetically. In weak fields ($p_\mathrm{m}B \ll kT$), the average magnetic moment is proportional to the magnetic induction. In strong fields, saturation is achieved, where all magnetic moments are oriented along the field and the magnetization virtually does not change. The orientational mechanism of paramagnetic magnetization is similar to that of polar dielectric polarization (see Subsection P3.5.2). In particular, the conclusion about inverse proportionality between the susceptibility and temperature remains valid.

► **Ferromagnets** are materials that show spontaneous magnetization in macroscopic (compared to interatomic distances) regions called *domains*. The domains are small ($\sim 10^{-5}$ to 10^{-4} m) as compared to the size of the sample under examination. Within each domain, spin magnetic moments are parallel to one another, which results from a special quantum interaction among them. In the absence of external magnetic fields, the domains are oriented in such a way that the average magnetization of the material is zero. When an external magnetic field is applied, the domains oriented along the field increase in size and the domains oriented against the field decrease. For stronger fields, the domains tend to turn as a whole to be oriented along the field. In strong enough fields, all domains are oriented along the field and saturation is achieved, when the magnetization reaches its maximum magnitude, J_sat, called the *saturation magnetization*.

The relationship between **J** and **H** is nonlinear (see Fig. P3.24). This means that the magnetic permeability, determined by the formula $\mathbf{J} = (\mu - 1)\mathbf{H}$, depends on H and attains very large values ($\mu \sim 10^5$–10^6). When the external field is removed, some *residual magnetization*, J_res, is observed. The field strength required to completely demagnetize the sample, H_C, is called the *coercive field* or *coercive force*. Ferromagnetic materials possessing a large coercive force are used to make permanent magnets. The dependence $J(H)$ for direct and reverse magnetization to saturation is called a *hysteresis loop*.

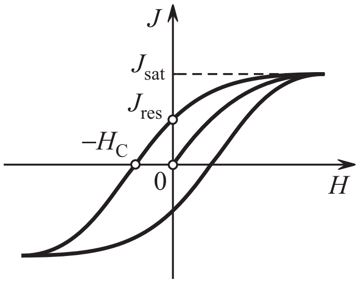

Figure P3.24. Hysteresis loop of a ferromagnetic material.

When heated above the *Curie temperature*, the material loses its ferromagnetic properties (spontaneous magnetization of domains disappears) and becomes a paramagnet. A second-order phase transition occurs at the Curie point.

P3.10. Electromagnetic Induction

P3.10.1. Faraday's Law of Electromagnetic Induction

► **Motion of a wire loop in a constant field.** When a current-carrying wire loop is moved or deformed in a constant magnetic field, the Ampère forces are everywhere perpendicular to the current and, according to (P3.8.3.4), perform mechanical work $\delta A_{\perp} = I\,d\Phi$. Since the total work done by the Lorentz force on any moving particle is zero, the same work (but opposite in sign) is performed by the magnetic field (i.e., the tangential component of the Lorentz force) on free charges moving through the wire. This gives rise to an additional electromotive force (*induced emf*) in the loop:

$$\delta A_{\parallel} = -I\,d\Phi = -(I\,dt)\frac{d\Phi}{dt} = \mathscr{E}\,dq, \qquad \mathscr{E} = -\frac{d\Phi}{dt}. \tag{P3.10.1.1}$$

► **Static loop. Solenoidal electric field.** It follows from Einstein's relativity principle that an induced emf must also arise when a static current-carrying loop is placed in a time varying magnetic field. Consider, for example, a permanent magnet approaching a closed loop at a constant velocity. In the magnet-associated inertial frame of reference, the field produced by the magnet is time independent and the induced emf in the loop is accounted for by the action of the Lorentz force. On the other hand, in the loop-associated inertial frame, the same emf is observed, but it cannot be caused by magnetic forces. Hence, the varying magnetic field must bring about an electric field. Since the work of this field around the loop must be nonzero, it follows that the field is not electrostatic—it is called a *solenoidal* (*eddy*) *electric field*. Thus, an induced emf arises in the loop regardless of the reason for which the magnetic flux through the loop changes. The induced emf equals

$$\mathscr{E} = -\frac{d\Phi}{dt}. \tag{P3.10.1.2}$$

This equation is known as *Faraday's law of electromagnetic induction*. The average induced emf in a finite time Δt equals $\mathscr{E}_{\text{ave}} = -\Delta\Phi/\Delta t$. The charge passed through the loop in this time is

$$q = \int I\,dt = \int \frac{\mathscr{E}}{R}\,dt = -\frac{\Delta\Phi}{R},$$

where R is the resistance of the loop.

► **Lenz's rule.** The direction of the emf is determined by its sign. It should be reminded (see Subsection P3.8.3) that the loop is *oriented*: the positive direction of the normal to the surface, in the formula for the calculation of Φ, and the positive direction of tracing the path, which determines the sign of the emf, are related by the right-hand rule. The minus sign in (P3.10.1.2) is in accordance with *Lenz's rule*. It states that the induced emf must be directed so that the magnetic field produced by the induced current flowing in the same direction, generates a magnetic flux (induced magnetic flux) of opposite sign as compared to the flux change that caused the emf. Lenz's rule is closely associated with the law of conservation of energy.

► **Motion of part of a loop.** When a loop element $d\mathbf{l}$ moves with a velocity $\mathbf{v}$, the work done by the Lorentz force to transfer a test charge q along $d\mathbf{l}$ equals $\delta A = q[\mathbf{v}\times\mathbf{B}]\cdot d\mathbf{l} = q\,d\mathscr{E}$. The electromotive forces induced by an arbitrarily moving portion of the loop in an arbitrary constant field and by a translationally moving portion of the loop in a uniform constant field are, respectively, equal to

$$\mathscr{E} = \int [\mathbf{v}\times\mathbf{B}]\cdot d\mathbf{l}, \qquad \mathscr{E} = [\mathbf{v}\times\mathbf{B}]\cdot \mathbf{l}, \tag{P3.10.1.3}$$

where $\mathbf{l}$ is the vector connecting the beginning and the end of the moving portion. If the wire loop is unclosed, a potential difference will arise between its ends, which is equal to the emf (since the electrostatic force is equalized by the Lorentz force at any point of the wire).

Example 1. A crosspiece of length l and resistance r moves with a speed v along two horizontal rails immersed in a vertical magnetic field (Fig. P3.25). Find the current through the crosspiece.

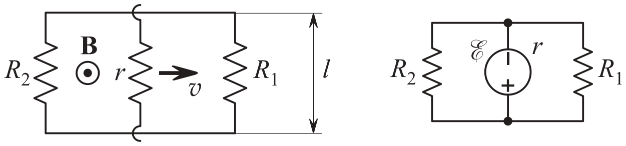

Figure P3.25. To example 1. An equivalent diagram is on the right.

Solution. Suppose that the rails are connected by a resistance R_1 on one side and a resistance R_2 on the other side. In order to find the current through the crosspiece as it moves with the speed v, we use (P3.10.1.3) to calculate the emf induced in the crosspiece: $\mathscr{E} = Bvl$. The fact that the emf is localized within the moving crosspiece enables us to draw an equivalent diagram, shown on the right, and eventually find the current: $I = \mathscr{E}/(r + R)$, where $R = R_1R_2/(R_1 + R_2)$.

► **Equations of solenoidal electric field.** By writing down Faraday's law (P3.10.1.2) for a static loop in a varying magnetic field, we obtain a solenoidal electric field equation in integral form:

$$\oint \mathbf{E}\cdot d\mathbf{l} = -\frac{d}{dt}\int \mathbf{B}\cdot d\mathbf{s}. \tag{P3.10.1.4}$$

Since the circulation of the electrostatic field strength around a closed path is zero, the total electric field satisfies the same equation. The differential form of this equation is

$$\operatorname{curl}\mathbf{E} = -\frac{\partial\mathbf{B}}{\partial t}. \tag{P3.10.1.5}$$

Equations (P3.10.1.4) and (P3.10.1.5) represent one of Maxwell's equation (in integral and differential forms).

► **Quasistationary approximation.** If the currents and fields change sufficiently slowly, time delay of processes can be neglected. This means that the varying magnetic field is determined at any point (using the Biot–Savart–Laplace formulas) by the currents at the same instant of time. This also means that the electrostatic field is determined by the charge distribution at the same instant and the solenoidal electric field is calculated from the varying magnetic field using (P3.10.1.4) and (P3.10.1.5). It is this approximation that is used for the analysis of alternating current circuits. For this approximation to be valid it is required that the characteristic current variation time, τ, is large compared to (a) the local relaxation times (e.g., the time in which an equilibrium charge distribution is established in the conductor) and (b) the delay time $\tau_{\rm d} = l/c$, where l is the characteristic size of the system and c is the speed of light. The latter condition suggests that we neglect the displacement current in Maxwell's equations (i.e., we assume that $\operatorname{curl}\mathbf{B} = \mu_0\mathbf{j}$).

Example 2. Let us estimate the time τ of charge redistribution in a conductor with resistivity ρ. We assume that there is a local volume charge somewhere in the conductor. The charge redistribution within an arbitrary volume is governed by the equation $\dfrac{dq}{dt} = -\oint j_n\,ds = -\dfrac{1}{\rho}\oint E_n\,ds = -\dfrac{q}{\varepsilon_0\rho}$, whence $q = q_0\exp\Bigl(-\dfrac{t}{\varepsilon_0\rho}\Bigr)$, and so $\tau = \varepsilon_0\rho$.

P3.10.2. Self-Induction and Mutual Induction

► **Self-induction.** Consider a stationary wire loop carrying current I changing in time. The magnetic induction produced by the current will change at a rate proportional to dI/dt. Hence, the solenoidal electric field arising at every point in space is also proportional to dI/dt. This field induces the emf

$$\mathscr{E}_{\rm self} = -L\frac{dI}{dt} \qquad \text{(P3.10.2.1)}$$

in the loop. This emf is called the *self-induction electromotive force*. The quantity L is called the *coefficient of self-inductance* or the *inductance* of the loop. The SI unit of inductance is the *henry* (H). The quantity $\Phi_{\rm self} = LI$ is the self-induced magnetic flux through the area spanned by the loop. Using (P3.10.2.1), we get

$$\mathscr{E}_{\rm self} = -\frac{d\Phi_{\rm self}}{dt}. \qquad \text{(P3.10.2.2)}$$

This formula remains valid not only if I changes but also if L does.

Note that the definition of L as the coefficient of proportionality between magnetic flux and current meets with difficulties: for a linear wire, the magnetic flux is infinitely large and for a wire of finite thickness, the usual definition of the flux is unsuitable, since it is unclear how to choose a path.

Example 1. Inductance of a solenoid. Consider a solenoid of length l and cross-sectional area S ($l \gg \sqrt{S}$) carrying current with surface density $i = (N/l)I$, where N is the number of turns and I is the current in the coil. The magnetic field in the solenoid is uniform and its magnetic induction (in the ideal solenoid approximation) is given by (P3.8.3.3): $B = \mu_0\mu i$. For a changing current, the circulation of the solenoidal electric field is calculated as $\oint \mathbf{E}\cdot d\mathbf{l} = -S\dfrac{dB}{dt} = -\mu_0\mu S\dfrac{di}{dt}$ and the emf induced along the whole length of the winding equals $\mathscr{E}_c = -N\mu_0\mu S\dfrac{di}{dt} = -\dfrac{N^2\mu_0\mu S}{l}\dfrac{dI}{dt}$. The inductance and the magnetic flux are expressed as

$$L = \frac{N^2\mu_0\mu S}{l}, \qquad \Phi_{\rm self} = LI = NBS. \qquad \text{(P3.10.2.3)}$$

Example 2. Since the self-induction emf is proportional to the current change rate, the presence of inductance in a circuit impedes too rapid changes of the current. Suppose that a resistor R and an induction coil L are in a closed circuit with a source of constant emf $\mathscr{E}$. The current increases from zero to $I_0 = \mathscr{E}/R$ in a finite time and this process is governed by the equation $\mathscr{E} - L(dI/dt) = IR$, whose solution is $I = I_0[1 - \exp(-tR/L)]$. Hence, the characteristic time of current increasing equals $\tau = L/R$.

► **Mutual induction.** If there are two stationary loops, the current change in one of them will bring about in the other loop an electromotive force proportional to dI/dt, called the *mutual induction emf.* We have

$$\mathscr{E}_{21} = -L_{21}\frac{dI_1}{dt}, \qquad \mathscr{E}_{12} = -L_{12}\frac{dI_2}{dt}, \tag{P3.10.2.4}$$

where L_{12} and L_{21} are the so-called *coefficients of mutual inductance*; the *mutuality theorem* (in a non-ferromagnetic medium) states that $L_{12} = L_{21}$. The magnetic flux through loop 1 produced by the current through loop 2 is given by $\Phi_{12} = L_{12}I_2$. This quantity is meaningful for two linear currents also.

In the quasistationary approximation, the vector potential can be calibrated in the same way as in magnetostatics (see Subsection P3.8.3). The magnetic flux can be written as

$$\Phi = \int \mathbf{B}\, d\mathbf{s} = \int \operatorname{curl} \mathbf{A}\, d\mathbf{s} = \oint \mathbf{A}\, d\mathbf{l}.$$

For Φ_{12}, we get

$$\Phi_{12} = \oint \mathbf{A}\, d\mathbf{l}_1 = \oint\oint \frac{\mu_0}{4\pi}\frac{I_2\, d\mathbf{l}_2}{r_{12}} d\mathbf{l}_1.$$

It is apparent that the expression of L_{12} is symmetric with respect to the subscripts 1 and 2.

P3.10.3. Energy of Magnetic Field

► **Energy of a loop.** The energy of a current-carrying loop is the work done by external forces and sources to create the current (or, equivalently, the work of the solenoidal field to destroy the current). The work done by the current source against the self-induction emf of the loop is calculated as

$$W = A = \int_0^\infty L\frac{dI}{dt}(I\,dt) = \frac{LI^2}{2}. \tag{P3.10.3.1}$$

Within a consistent field approach, the energy must be related with the magnetic field rather than the loop current. The easiest way to find the dependence between the energy density and the magnetic induction is to consider a long solenoid with a uniform field in it. We have

$$\frac{W}{V} = \frac{1}{Sl}\frac{\mu_0\mu N^2 S}{l}\frac{I^2}{2} = \left(\frac{\mu_0\mu IN}{l}\right)^2\frac{1}{2\mu_0\mu} = \frac{B^2}{2\mu_0\mu} = \frac{BH}{2}. \tag{P3.10.3.2}$$

If the relationship between **B** and **H** is nonlinear, the energy density is expressed as

$$\frac{W}{V} = \int \mathbf{H}\cdot d\mathbf{B}.$$

Using the mutuality theorem ($L_{12} = L_{21}$), we can generalize (P3.10.3.1) to include two loops:

$$\begin{aligned} W &= \int_0^\infty \left(L_1\frac{dI_1}{dt} + L_{12}\frac{dI_2}{dt}\right)(I_1\,dt) + \int_0^\infty \left(L_2\frac{dI_2}{dt} + L_{21}\frac{dI_1}{dt}\right)(I_2\,dt) \\ &= \frac{L_1I_1^2}{2} + \frac{L_2I_2^2}{2} + \frac{L_{12}+L_{21}}{2}I_1I_2 = \frac{I_1\Phi_1}{2} + \frac{I_2\Phi_2}{2}. \end{aligned} \tag{P3.10.3.3}$$

Likewise, for several loops, we have

$$W=\sum_i \frac{I_i\Phi_i}{2},$$

where Φ_i is the total magnetic flux through the ith loop. It can be seen that the current energy includes the energy of each individual current and the energy of their interaction. With the magnetic field equations, it can be shown that the above expression always converts to

$$W=\int \frac{B^2}{2\mu_0\mu}\,dV=\int \frac{BH}{2}\,dV. \qquad \text{(P3.10.3.4)}$$

► **Law of conservation of energy and force calculation.** If the positions of the bodies and current-carrying loops change sufficiently slowly and isothermally, the total work done by external forces and current sources is spent on changing the magnetic field energy and releasing Joulean heat. Moreover, the work done by external forces on each body equals the work done by the magnetic forces on the body. If the currents are maintained constant, one has only to take into account the additional work done by the current sources against the induction emf; the work done by the original emf equals the heat released and, hence, they cancel each other out in the law of conservation of energy.

Example. Consider two loops carrying currents I_1 and I_2 that are maintained constant. Let us calculate the work A^e done by external forces for a slow movement of the first loop. According to (P3.10.3.3), the changing part of the energy is only the energy of current interaction, which is equal to $W_{12}=L_{12}I_1I_2=I_1\Phi_{12}$, where Φ_{12} is the magnetic flux created by the second current and passing through the first loop. At the same time, the potential function of the loop in an external field is $W_\mathrm{p}=-I_1\Phi_{12}$ (see (P3.8.3.5)), and hence $\delta A^\mathrm{e}=-I_1\,d\Phi_{12}=-I_1I_2\,dL_{12}$. The apparent contradiction is resolved by taking into account the additional work done by the current sources against the induction emf in either loop. This work equals $\delta A^\mathrm{sources}=I_1\,d\Phi_{12}+I_2\,d\Phi_{21}=I_1\,dL_{12}\,I_2+I_2\,dL_{21}\,I_1$, which is twice the field energy change $dW_{12}=I_1I_2\,dL_{12}$, and $\delta A^\mathrm{e}+\delta A^\mathrm{sources}=dW_{12}$.

P3.11. Maxwell's Equations

P3.11.1. Maxwell's Equations in Vacuum and Matter

► **Displacement current.** To generalize the electromagnetic field equations in vacuum to cover varying fields, only one of the four equations (see Subsections P3.3.2, P3.8.3, and P3.10.1) has to be changed. Three equations hold true in all cases but Ampère's circuital law (P3.8.3.1) turns out to be invalid for varying fields and currents. According to (P3.8.3.1), the current $\int \mathbf{j}\cdot d\mathbf{s}$ must be the same for any two surfaces spanning the closed path; if the charge within the volume between the two selected surfaces changes, this statement will contradict the principle of conservation of charge. For example, when a parallel-plate capacitor is being charged (Fig. P3.26), the current through one of the surfaces is $I=dq/dt$ and there in no current through the other surface (passing between the plates).

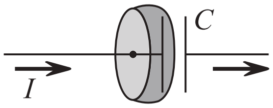

Figure P3.26. To the determination of the displacement current.

To remove the contradiction, Maxwell introduced a *displacement current* in the equation, with its density proportional to the rate of change of the electric field $\mathbf{D}$:

$$\mathbf{j}_\mathrm{d}=\frac{\partial \mathbf{D}}{\partial t}. \qquad \text{(P3.11.1.1)}$$

In a dielectric medium, the displacement current density equals

$$\mathbf{j}_{\rm d} = \varepsilon_0 \frac{\partial \mathbf{E}}{\partial t} + \frac{\partial \mathbf{P}}{\partial t}. \tag{P3.11.1.2}$$

The first term represents the displacement current density in vacuum and the second term is the real current density due to motion of bound charges in changing polarization. The displacement current through a surface equals $d\Phi_D/dt$, where Φ_D is the flux of **D** through the surface. The introduction of the displacement current removes the contradiction with the principle of conservation of charge. For example, when a parallel-plate capacitor is being charged, the displacement current through a surface between the plates, $I_{\rm d} = S(dD/dt) = S(d\sigma/dt) = dq/dt$, equals the current flowing through the wires.

► **System of Maxwell's equations in vacuum.** Once the displacement current has been introduced, the system of Maxwell's equations in differential form becomes:

1) $\operatorname{curl}\mathbf{E} = -\dfrac{\partial \mathbf{B}}{\partial t}$ (Faraday's law of induction)

2) $\operatorname{curl}\mathbf{B} = \mu_0\mathbf{j} + \mu_0\varepsilon_0\dfrac{\partial \mathbf{E}}{\partial t}$ (Ampère's circuital law with Maxwell's correction)

3) $\operatorname{div}\mathbf{E} = \dfrac{\rho}{\varepsilon_0}$ (Gauss's law)

4) $\operatorname{div}\mathbf{B} = 0$ (Gauss's law for magnetism)

The system of Maxwell's equations in integral form:

$$1)\ \oint \mathbf{E}\cdot d\mathbf{l} = -\frac{d}{dt}\int \mathbf{B}\cdot d\mathbf{s}, \qquad 2)\ \oint \mathbf{B}\cdot d\mathbf{l} = \mu_0\int \mathbf{j}\cdot d\mathbf{s} + \mu_0\varepsilon_0\frac{d}{dt}\int \mathbf{E}\cdot d\mathbf{s},$$

$$3)\ \oint \mathbf{E}\cdot d\mathbf{s} = \frac{1}{\varepsilon_0}\int \rho\, dV, \qquad 4)\ \oint \mathbf{B}\cdot d\mathbf{s} = 0.$$

The charge density and the current density satisfy the relation

$$\oint \mathbf{j}\cdot d\mathbf{s} = -\frac{d}{dt}\int \rho\, dV \qquad \Big(\operatorname{div}\mathbf{j} = -\frac{\partial\rho}{\partial t}\Big),$$

which expresses the law of conservation of charge and is a corollary of Maxwell's equations.

► **Solution of Maxwell's equations in the form of delayed potentials.** The first and fourth Maxwell equations can be satisfied by using the fields in the form

$$\mathbf{B} = \operatorname{curl}\mathbf{A}, \qquad \mathbf{E} = -\operatorname{grad}\varphi - \frac{\partial \mathbf{A}}{\partial t}.$$

The scalar potential φ and vector potential **A** are defined up to the *calibration transformation*:

$$\mathbf{A}' = \mathbf{A} + \operatorname{grad}\chi, \qquad \varphi' = \varphi - \frac{\partial\chi}{\partial t}.$$

The equations for the potentials resulting from the second and third Maxwell equations can be simplified using the calibration transformation. To this end, the potentials are required to satisfy *Lorentz's calibration condition*:

$$\operatorname{div}\mathbf{A} + \frac{1}{c^2}\frac{\partial\varphi}{\partial t} = 0.$$

In this case, the equations for the potentials satisfy *d'Alembert's equation*:

$$\Delta\mathbf{A} - \frac{1}{c^2}\frac{\partial^2\mathbf{A}}{\partial t^2} = -\mu_0\mathbf{j}, \qquad \Delta\varphi - \frac{1}{c^2}\frac{\partial^2\varphi}{\partial t^2} = -\frac{\rho}{\varepsilon_0}.$$

If the right-hand side vanishes, d'Alembert's equation becomes the wave equation (see Chapter P4). In the presence of time-varying current and charge sources, d'Alembert's equations have solutions in the form of *delayed potentials*:

$$\mathbf{A}(\mathbf{r},t)=\frac{\mu_0}{4\pi}\int\frac{\mathbf{j}\big(\mathbf{r}',t-\frac{|\mathbf{r}-\mathbf{r}'|}{c}\big)\,dV'}{|\mathbf{r}-\mathbf{r}'|},\qquad \varphi(\mathbf{r},t)=\frac{1}{4\pi\varepsilon_0}\int\frac{\rho\big(\mathbf{r}',t-\frac{|\mathbf{r}-\mathbf{r}'|}{c}\big)\,dV'}{|\mathbf{r}-\mathbf{r}'|}.$$

The potentials at a given point in space and a given time instant are determined by the charges and currents at all other points at preceding instants of time, taking into account the time required for a light signal to deliver information to the given point about the current and charge values at a remote point.

► **Maxwell's equations in a medium** are written as

differential form	integral form
1) $\operatorname{curl}\mathbf{E}=-\dfrac{\partial\mathbf{B}}{\partial t}$,	$\oint\mathbf{E}\cdot d\mathbf{l}=-\dfrac{d}{dt}\int\mathbf{B}\cdot d\mathbf{s}$,
2) $\operatorname{curl}\mathbf{H}=\mathbf{j}+\dfrac{\partial\mathbf{D}}{\partial t}$,	$\oint\mathbf{H}\cdot d\mathbf{l}=\int\mathbf{j}\cdot d\mathbf{s}+\dfrac{d}{dt}\int\mathbf{D}\cdot d\mathbf{s}$,
3) $\operatorname{div}\mathbf{D}=\rho$,	$\oint\mathbf{D}\cdot d\mathbf{s}=\int\rho\,dV$,
4) $\operatorname{div}\mathbf{B}=0$,	$\oint\mathbf{B}\cdot d\mathbf{s}=0$.

These serve to determine the four vector quantities **E**, **D**, **B**, and **H**. Maxwell's equations in a medium must be supplemented by the *material equations* relating **D** to **E** and **H** to **B** and characterizing the electric and magnetic properties of the medium. For isotropic linear media, the equations are

$$\mathbf{D}=\varepsilon_0\varepsilon\mathbf{E},\qquad \mathbf{B}=\mu_0\mu\mathbf{H}.$$

Maxwell's equations can also be used to obtain boundary conditions for **E**, **D**, **B**, and **H** (see Subsections P3.5.1 and P3.9.1).

P3.11.2. Law of Conservation of Energy for Electromagnetic Fields

► **Poynting vector.** The following equation for any volume V bounded by a surface S can be derived from Maxwell's equations:

$$\frac{d}{dt}\int\Big(\frac{\varepsilon_0E^2}{2}+\frac{B^2}{2\mu_0}\Big)dV+\int\big(\mathbf{j}\cdot\mathbf{E}\big)\,dV+\frac{1}{\mu_0}\oint\big[\mathbf{E}\times\mathbf{B}\big]\cdot d\mathbf{s}=0.$$

The first term characterizes the rate of change of electromagnetic field energy in the volume. In general, the formulas obtained before for electrostatic and magnetostatic fields remain valid for the electromagnetic field energy. The second term represents the power of the field work on the charged particles within the volume of interest; it is equal to the rate of change of their kinetic energy. It follows from the law of conservation of energy that the third term has the meaning of (outward) electromagnetic energy flux through the closed surface bounding the volume. The energy flux at a given point in space (the *Poynting vector*) is determined by the vectors **E** and **B** at this point:

$$\mathbf{S}=\frac{1}{\mu_0}\mathbf{E}\times\mathbf{B}=\mathbf{E}\times\mathbf{H}. \qquad \text{(P3.11.2.1)}$$

The last expression represents the electromagnetic energy flux in a substance. The energy density in a substance is expressed as

$$w = \tfrac{1}{2}\mathbf{E}\cdot\mathbf{D} + \tfrac{1}{2}\mathbf{B}\cdot\mathbf{H}. \qquad \text{(P3.11.2.2)}$$

Example. Consider the process of charging a parallel-plate capacitor with circular plates separated by a distance b. The rate of change of the energy in a cylinder of radius r (smaller than the plate radius) equals $\dfrac{d}{dt}\big(\tfrac{1}{2}\varepsilon_0\varepsilon E^2\big)(\pi r^2 b) = \pi r^2 bE\dfrac{dD}{dt}$. The magnetic field strength can be found from the second Maxwell equations: $H\times 2\pi r = \dfrac{dD}{dt}\pi r^2$ (displacement current is on the right-hand side). We find that the rate of energy influx through the lateral surface of the cylinder, $S(2\pi rb) = HE(2\pi rb) = E\pi r^2 b\dfrac{dD}{dt}$, equals the energy change in the volume.

P3.11.3. Relativistic Properties of Fields

► **Transformation of charges and currents.** When changing from one inertial frame of reference to another, both the electromagnetic field sources (charge and current densities) and the fields themselves change. However, Maxwell's equations remain the same. The source transformation formulas for ρ (density of moving charge) and $\mathbf{j} = \rho\mathbf{v}$ have the simplest form. Denoting by ρ_0 the charge density in the inertial frame where $\mathbf{j} = \mathbf{v} = 0$ and taking into account length contraction (see Subsection P1.10.3), we get

$$\rho = \gamma\rho_0, \quad \mathbf{j} = \gamma\rho_0\mathbf{v}; \qquad \gamma = \frac{1}{\sqrt{1 - v^2/c^2}}.$$

Comparing with the momentum-energy 4-vector, we see that $(\mathbf{j}, \rho c)$ also forms a 4-vector, which means that $\mathbf{j}$ and ρc are transformed in the same manner as $(\mathbf{r}, ct)$, by the Lorentz formulas.

► **Transformation of fields.** Once we know the transformation formulas for field sources, it is not difficult to find out how $\mathbf{E}$ and $\mathbf{B}$ are transformed. The formulas are

$$\begin{aligned} \mathbf{E}'_{\parallel} &= \mathbf{E}_{\parallel}, & \mathbf{E}'_{\perp} &= \gamma\big(\mathbf{E}_{\perp} + \mathbf{V}\times\mathbf{B}\big), \\ \mathbf{B}'_{\parallel} &= \mathbf{B}_{\parallel}, & \mathbf{B}'_{\perp} &= \gamma\Big(\mathbf{B}_{\perp} - \frac{1}{c^2}\mathbf{V}\times\mathbf{E}\Big), \end{aligned} \qquad \text{(P3.11.3.1)}$$

where $\mathbf{V}$ is the velocity of inertial frame K' relative to inertial frame K; the transformations are written for the field components parallel and perpendicular to $\mathbf{V}$. The scalar quantities $\mathbf{E}\cdot\mathbf{B}$ and $E^2 - c^2B^2$ are invariant under these transformations:

$$\mathbf{E}\cdot\mathbf{B} = \mathbf{E}'\cdot\mathbf{B}', \qquad E^2 - c^2B^2 = (E')^2 - c^2(B')^2. \qquad \text{(P3.11.3.2)}$$

For $V \ll c$, formulas (P3.11.3.1) simplify to

$$\mathbf{E}' = \mathbf{E} + \mathbf{V}\times\mathbf{B}, \qquad \mathbf{B}' = \mathbf{B} - \frac{1}{c^2}\mathbf{V}\times\mathbf{E}. \qquad \text{(P3.11.3.3)}$$

Example 1. Magnetic field of a nonrelativistic particle. Consider a particle with charge q moving relative to inertial frame K with a constant nonrelativistic velocity $\mathbf{v}$. In the particle associated inertial frame K', there is only the electric field $\mathbf{E}' = kq\mathbf{r}'/r'^3$. To find the fields in frame K, one has to write out the transformation formulas (P3.11.3.3) with $\mathbf{V} = -\mathbf{v}$. Since there is no length contraction in the nonrelativistic limit, we find that

$$\mathbf{E} = \mathbf{E}' = \frac{1}{4\pi\varepsilon_0}\frac{q\mathbf{r}}{r^3}, \quad \mathbf{B} = \frac{\mathbf{v}\times\mathbf{E}'}{c^2} = \frac{\mu_0 q}{4\pi}\frac{\mathbf{v}\times\mathbf{r}}{r^3}$$

for the instant when the particle passes through the origin of coordinates in frame K. In deriving these formulas, we have used the relation $1/c^2 = \mu_0\varepsilon_0$.

Example 2. Polarization of a dielectric moving in a magnetic field. When a dielectric moves through a magnetic field with an nonrelativistic velocity perpendicular to the magnetic field lines, it becomes polarized. In the dielectric-associated inertial frame, there is transverse electric field: $\mathbf{E}' = \mathbf{v}\times\mathbf{B}$. The detailed polarization picture depends on the shape of the dielectric.

Example 3. Electric field of a relativistic particle. Suppose a particle with charge q moves relative to inertial frame K with a constant relativistic velocity $\mathbf{v}$. In the particle associated inertial frame K', there is only the electric field $\mathbf{E}' = kq\mathbf{r}'/r'^3$. To find the fields in frame K, one has to write out the transformation formulas (P3.11.3.1) with $\mathbf{V} = -\mathbf{v}$. Let us write out the formulas for the instant when the particle passes through the origin of coordinates in frame K. For simplicity, consider the plane (x, y). When changing from the coordinates (x', y') to (x, y), we must take into account that $x' = \gamma x$ and $y' = y$ (the coordinates of a point in frame K are measured at the same instant when the particle passes through the origin). We get

$$E_x = E'_x = k\frac{q\gamma x}{[(\gamma x)^2 + y^2]^{3/2}}, \qquad E_y = \gamma E'_y = k\frac{q\gamma y}{[(\gamma x)^2 + y^2]^{3/2}}.$$

It is seen that $\mathbf{E}$ is collinear with $\mathbf{r}$. However, the field at a point on the line of motion will be smaller than that at a point which is at the same distance from the charge but on a straight line perpendicular to $\mathbf{v}$. The magnetic field is obtained as

$$\mathbf{B} = \frac{\gamma}{c^2}\mathbf{v}\times\mathbf{E}' = \frac{1}{c^2}\mathbf{v}\times\mathbf{E} = \frac{\mu_0}{4\pi}\frac{\gamma q\,\mathbf{v}\times\mathbf{r}}{[(\gamma x)^2 + y^2]^{3/2}}.$$

Note that the above electric field is not potential.

Chapter P4

Oscillations and Waves

P4.1. Oscillations

► **General definitions.** Oscillations are repetitive variations in the state of a system such that the state parameters vary in time according to a periodic or almost periodic law. If oscillations occur without external action due to system deviation from a stable equilibrium, the oscillations are said to be *free* or *natural*. If the oscillations occur under the action of an external periodic force, then they are said to be *forced*. The oscillations are characterized by their *period* T and *frequency* $\nu = 1/T$ (measured in *hertzs*: $1\,\mathrm{Hz} = 1\,\mathrm{s}^{-1}$). The term *vibrations* is often used in a narrower sense to mean mechanical oscillations, but sometimes is used synonymously with oscillations.

P4.1.1. Harmonic Oscillations. Composition of Oscillations

► **Simple harmonic oscillations.** An oscillation of a quantity x is said to be a *simple harmonic oscillation* (or *simple harmonic motion*) if x varies in time t by the law

$$x = A\cos(\omega t + \varphi_0), \qquad \text{(P4.1.1.1)}$$

where A is the *amplitude*, $\varphi = \omega t + \varphi_0$ is the *phase*, φ_0 is the *initial phase*, and $\omega = 2\pi/T$ is the *angular* or *circular frequency* of the oscillation. The first and second time-derivatives of the quantity x,

$$\begin{aligned} \dot{x} &= -A\omega\sin(\omega t + \varphi_0) = A\omega\cos\bigl(\omega t + \varphi_0 + \pi/2\bigr), \\ \ddot{x} &= -A\omega^2\cos(\omega t + \varphi_0) = A\omega^2\cos(\omega t + \varphi_0 + \pi), \end{aligned} \qquad \text{(P4.1.1.2)}$$

oscillate harmonically with the same frequency but with amplitudes ωA and $\omega^2 A$ and with the phase shifts $\pi/2$ and π, respectively.

Example. If the initial values (at $t = 0$) of the quantity x and its derivative, $x(0) = x_0$ and $\dot{x}(0) = v_0$, are known, then the amplitude and the initial phase of the oscillation can be determined. The equations $x_0 = A\cos\varphi_0$ and $v_0 = -\omega A\sin\varphi_0$ allow one to find $A = \sqrt{x_0^2 + (v_0/\omega)^2}$ and $\tan\varphi_0 = -v_0/(\omega x_0)$.

► **Equation of simple harmonic oscillations.** It follows from (P4.1.1.2) that if x varies by the harmonic law (P4.1.1.1), then x satisfies the *equation of simple harmonic oscillations*:

$$\ddot{x} + \omega^2 x = 0. \qquad \text{(P4.1.1.3)}$$

The converse is also true: if the *equation of motion* of a physical system whose state is determined by a single quantity x can be reduced under certain conditions (usually, for small values of x) to the differential equation $\ddot{x} + \gamma x = 0$, where γ is a positive constant, then x varies according to the law (P4.1.1.1) with $\omega = \sqrt{\gamma}$ (the parameters A and φ_0 are determined by the initial conditions; see the example above).

► **Energy method for determining the frequency.** If the state of a physical system undergoes repetitive variations and the quadratic function

$$E = \tfrac{1}{2}\mu\dot{x}^2 + \tfrac{1}{2}\kappa x^2 \qquad (\mu \text{ and } \kappa \text{ are positive constants}) \tag{P4.1.1.4}$$

remains constant during these variations, then x changes according to the law (P4.1.1.1) with $\omega = \sqrt{\kappa/\mu}$. Indeed, differentiating (P4.1.1.4) with respect to time, we obtain the equation $\mu\ddot{x} + \kappa x = 0$, which is the equation of simple harmonic oscillations. Usually, the quantity E is proportional to the energy of the oscillatory system for small x; accordingly, such an approach is called the *energy method* for determining the oscillation frequency.

► **Complex exponential and vector diagram.** Using Euler's formula $e^{i\varphi} = \cos\varphi + i\sin\varphi$, one can treat the law of harmonic oscillations (P4.1.1.1) as the real part of a complex exponential function, $x(t) = \operatorname{Re}\widetilde{x}$, where

$$\widetilde{x} = \widetilde{A}\exp(i\omega t), \tag{P4.1.1.5}$$

and $\widetilde{A} = A\exp(i\varphi_0)$ is called the *complex amplitude* of oscillations. This technique is especially convenient for studying systems described by linear equations, since, in this case, the real and imaginary parts are transformed independently of each other.

The harmonic law (P4.1.1.1) can be obtained as the projection on the x-axis of a radius vector of length A that uniformly rotates counterclockwise with a constant angular velocity ω from an initial angular position φ_0; in this case, the angle made with the axis x varies by the law $\varphi = \varphi_0 + \omega t$. This technique is called the *method of vector diagrams*; it is especially convenient for the *composition of harmonic oscillations*. With this technique, the addition of functions is replaced by the graphical addition of vectors; note that the projection of the sum of vectors is equal to the sum of their individual projections.

► **Composition of harmonic oscillations of a single direction.** The sum of two harmonic oscillations of the same frequency with amplitudes A_1 and A_2 and the initial phases φ_1 and φ_2 is a harmonic oscillation of the same frequency, whose amplitude and initial phase can be found by the method of vector diagrams (Fig. P4.1):

$$A^2 = A_1^2 + A_2^2 + 2A_1A_2\cos(\varphi_2 - \varphi_1), \qquad \tan\varphi_0 = \frac{A_1\sin\varphi_1 + A_2\sin\varphi_2}{A_1\cos\varphi_1 + A_2\cos\varphi_2}.$$

The parallelogram spanned by the vectors rotates with angular velocity ω as a rigid body. The phase difference of oscillations with the same frequency does not vary in time; such oscillations are said to be *coherent*. If $\varphi_2 - \varphi_1 = \pm 2m\pi$, the amplitude is a maximum, $A = A_1 + A_2$, and if $\varphi_2 - \varphi_1 = \pm(2m+1)\pi$, the amplitude is a minimum, $A = |A_1 - A_2|$.

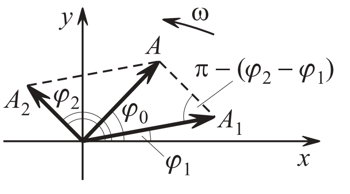

Figure P4.1. Composition of oscillations by the method of vector diagrams.

In the vector addition of incoherent oscillations with different frequencies, the parallelogram spanned by the vectors deforms with time and the magnitude of the resultant vector and its angular velocity vary, and hence the composite motion is not a harmonic oscillation. However, oscillations *with close frequencies* ($\Delta\omega = |\omega_1 - \omega_2| \ll \max\{\omega_1, \omega_2\}$) can be assumed to be approximately coherent on a sufficiently short time interval as compared to the *time of coherence* $\tau_{\rm coh} = 2\pi/\Delta\omega$. The composite oscillation will occur with the angular frequency $\omega = (\omega_1 + \omega_2)/2$ and an amplitude periodically varying between $A_1 + A_2$ and $|A_1 - A_2|$ with period $2\pi/\Delta\omega$. Such oscillations are called *beats*, $\omega_{\rm b} = \Delta\omega$ is the beat angular frequency, and the period of variation in the amplitude $T_{\rm b} = 2\pi/\omega_{\rm b}$ is the beat period. If $A_1 = A_2 = A$, then

$$x(t) = 2A\cos\Bigl(\frac{\omega_2 - \omega_1}{2}t\Bigr)\cos\Bigl(\frac{\omega_2 + \omega_1}{2}t + \varphi_0\Bigr).$$

The beats are an example of *modulated oscillations*, or oscillations obeying the harmonic law (P4.1.1.1) with one of the parameters (amplitude, frequency, or phase) varying periodically in time with a period significantly greater than that of the base oscillations. Amplitude, frequency, and phase modulation techniques are distinguished.

An arbitrary periodic oscillation with period T can be expanded into a *Fourier series* in simple harmonic oscillations with frequencies $\omega_n = n(2\pi/T)$. Such a representation is called the *harmonic analysis* of the periodic oscillation. The Fourier series terms are called the first (fundamental), second, third, etc. *harmonics* of the periodic oscillation. Aperiodic oscillations have, as a rule, a continuous spectrum of frequencies and can be represented as a *Fourier integral* in harmonic oscillations of all frequencies ranging from zero to infinity. All periodic oscillations have a line (discrete) spectrum of frequencies, but oscillations with a line spectrum are not necessarily periodic.

► **Composition of mutually perpendicular harmonic oscillations.** If a point moves in the plane so that its projections on the x- and y-axes oscillate harmonically, this motion is said to be the composition of mutually perpendicular simple harmonic oscillations. If the oscillations in either coordinate have *equal frequencies*, $x = A_1\cos(\omega t + \varphi_1)$ and $y = A_2\cos(\omega t + \varphi_2)$, the path of the point is an inclined ellipse:

$$\frac{x^2}{A_1^2} + \frac{y^2}{A_2^2} - \frac{2xy}{A_1A_2}\cos(\varphi_2 - \varphi_1) = \sin^2(\varphi_2 - \varphi_1).$$

Such a motion is called an *elliptically polarized oscillation*. If $\varphi_2 - \varphi_1 = (2m + 1)\pi/2$, the ellipse axes coincide with the coordinate axes. If $\varphi_2 - \varphi_1 = m\pi$, the ellipse degenerates into a straight line segment; such a motion is called a *linearly polarized oscillation*. The point can move clockwise (for $2m\pi < \varphi_2 - \varphi_1 < 2m\pi + \pi$) or counterclockwise; in these cases, one speaks about the right or left elliptic polarization.

Two-dimensional harmonic motions with frequencies ω_1 and ω_2 occur along curves called *Lissajous figures*. If the frequency ratio ω_1/ω_2 is a rational number, these figures are closed curves. Closed Lissajous figures can be used to determine the frequency ratio.

P4.1.2. Free Undamped Oscillations

► **Free mechanical oscillations with a single degree of freedom.** If the displacement of a conservative mechanical system from a stable equilibrium is described by a single parameter x, then for small x, the potential energy has the form

$$E_{\rm p}(x) = \frac{1}{2}x^2\left(\frac{d^2E_{\rm p}}{dx^2}\right)_{x=0} + \frac{1}{6}x^3\left(\frac{d^3E_{\rm p}}{dx^3}\right)_{x=0} + \cdots \approx \frac{\kappa x^2}{2}. \qquad \text{(P4.1.2.1)}$$

It follows that small oscillations of the system about its stable equilibrium occur harmonically. The potential energy of an oscillatory system is usually reckoned from the stable equilibrium ($E_\text{p} = 0$ for $x = 0$). For small x, the *generalized force*, $F_x = -dE_\text{p}/dx$, is proportional to the displacement: $F_x = -\kappa x$. (If x is a linear coordinate, then the generalized force is the force projection on the displacement direction, and if x is an angle, then F_x is a torque.)

If a mechanical system is a point particle or a translationally moving body, then the kinetic energy of the system has the form $E_\text{k} = \frac{1}{2}m\dot{x}^2$. The equation of motion

$$m\ddot{x} = -\kappa x \qquad \text{(P4.1.2.2)}$$

has the same form as that of a mass attached to a spring. For small x, the *restoring force* acting on the body (i.e., the force that tends to bring the body back to the equilibrium) is called the *quasielastic force*, $F_x = -\kappa x$, and the coefficient κ is the *effective spring constant*. The angular frequency and oscillation period are expressed as

$$\omega = \sqrt{\frac{\kappa}{m}}, \qquad T = 2\pi\sqrt{\frac{m}{\kappa}}. \qquad \text{(P4.1.2.3)}$$

The particle oscillates harmonically, $x = A\cos(\omega t + \varphi_0)$, and its kinetic and potential energies oscillate harmonically with the frequency 2ω:

$$E_\text{k} = E\sin^2(\omega t + \varphi_0) = \tfrac{1}{2}E\bigl[1 - \cos(2\omega t + 2\varphi_0)\bigr],$$
$$E_\text{p} = E\cos^2(\omega t + \varphi_0) = \tfrac{1}{2}E\bigl[1 + \cos(2\omega t + 2\varphi_0)\bigr],$$

where $E = \frac{1}{2}m\omega^2 A^2 = \frac{1}{2}\kappa A^2$ is the total mechanical energy, which is proportional to the amplitude squared. The average kinetic energy is equal to the average potential energy.

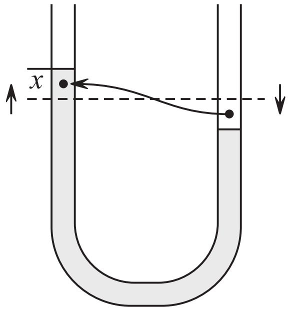

Figure P4.2. To example 1.

Example 1. If the level of a liquid in an U-shaped tube (Fig. P4.2) is displaced by a distance x from equilibrium, the potential energy of the liquid increases by $\Delta mgx = (\rho Sx)gx = (2\rho gS)x^2/2$ (where ρ is the liquid density and S is the tube cross-section) and the kinetic energy is equal to $m\dot{x}^2/2$. Hence the angular frequency of oscillations is equal to $\omega = \sqrt{2\rho gS/m}$.

Example 2. In one of the early models of the hydrogen atom (the Thomson model), it was assumed that the positive charge is uniformly distributed across a ball of radius R, equal to the atomic radius, and the electron was placed at the center of the ball. Let us find the frequency of electron oscillations when it is displaced from the equilibrium. If r denotes the displacement, the attraction force is equal to $F_r = -ke^2 r/R^3$ (see Subsection P3.3.2). Hence, for small displacements, $r < R$, there occur harmonic oscillations with frequency $\omega = \sqrt{ke^2/(mR^3)}$.

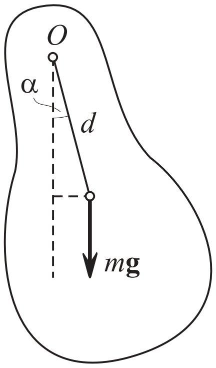

Figure P4.3. Physical pendulum.

Example 3. Physical pendulum. The *physical pendulum* is a rigid body whose horizontal immovable axis of rotation does not pass through its center of mass. For the pendulum deviation from equilibrium by a small angle α (Fig. P4.3), there arises a moment of the gravity force equal to $M = -mgd \sin\alpha$ (d is the distance from the center of mass to the axis of rotation), which tends to return the pendulum to equilibrium. The equation of rotational motion of the rigid body has the form: $I\ddot{\alpha} = -mgd \sin\alpha$, where I is the moment of inertia of the body about the axis of rotation. For small deviation angles $\alpha \ll 1$, this equation becomes the equation of harmonic oscillations with respect to the angle α: $\ddot{\alpha} + (mgd/I)\alpha = 0$. The pendulum angular frequency and oscillation period are equal to

$$\omega = \sqrt{mgd/I}, \qquad T = 2\pi\sqrt{I/(mgd)}.$$

For example, for a homogeneous rod of length l suspended by one of its ends, we obtain $I = ml^2/3$, $d = l/2$, $T = 2\pi\sqrt{2l/(3g)}$. The *reduced length* L of a physical pendulum is the length of a mathematical pendulum such that its period $T = 2\pi\sqrt{L/g}$ is equal to the period of the given physical pendulum: $L = I/(md)$. (For a homogeneous rod suspended by an end, we have $L = 2l/3$.) The point lying at a distance L from the suspension axis on the straight line passing through the center of mass perpendicularly to the suspension axis is called the *center of oscillation*. If a body is suspended on the axis passing through the center of oscillation parallel to the previous axis, then the oscillation period, and hence the pendulum reduced length do not change.

In this example, the generalized force is the moment of gravity force. The frequency can also be determined by the energy method if the dependence of the potential energy on the deviation angle is found: $E_\text{p} = mgd(1-\cos\alpha) \approx mgd\alpha^2/2$. For the total energy, we obtain $E = \frac{1}{2}I\dot{\alpha}^2 + \frac{1}{2}mgd\alpha^2$, which implies the oscillation frequency.

► **Isochronism of harmonic oscillations.** The harmonic oscillations are *isochronous*, which means that their period is independent of the amplitude. The point is that, in the equation of harmonic oscillations $\ddot{x} + \gamma x = 0$, the coefficient γ has dimension s^{-2} and it follows from the dimension considerations that the period cannot depend on anything else except for γ. The oscillations of large amplitude cease to be harmonic and hence isochronous; the period begins to depend on the amplitude. But in several special cases, even small oscillations may not be isochronous. This occurs if the second derivative in formula (P4.1.2.1) for the expansion of E_p in x is zero. Such a situation arises, for example, in the case where a load fixed at the middle of an *unstrained* spring with fixed ends deviates in the direction perpendicular to the spring. For small x, the potential energy is proportional to x^4, and the equation of motion has the form: $\ddot{x} + \gamma x^3 = 0$. In this case, the dimension γ is $\text{m}^{-2}\text{s}^{-2}$, and the oscillation period $T \sim \gamma^{-1/2}A^{-1}$ is inversely proportional to the amplitude.

► **Oscillatory systems with several degrees of freedom.** If the system displacement from the stable equilibrium is characterized by N independent parameters $x_1, \ldots, x_N$, then for an arbitrarily small initial deviation, the dependence $x_i(t)$ cannot be harmonic oscillations. But any motion can be represented as the sum of N special motions called *normal vibrational modes*, in each of which, all x_i harmonically oscillate with a angular

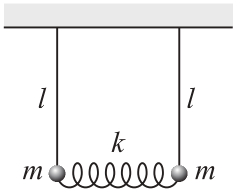

Figure P4.4. Coupled pendulums.

frequency characterizing this mode. In the general case, all the N frequencies can be distinct.

Example 4. Coupled pendulums. We consider two equal mathematical pendulums of length l whose loads are connected by an unstrained spring of rigidity k (Fig. P4.4). The normal modes of this system can be guessed because of the system symmetry. Harmonic oscillations arise for: (a) equal deviations of the pendulums to the same side ($x_1 = x_2$) and (b) for the equal deviations of the pendulums to opposite sides ($x_1 = -x_2$). In the first case: $\omega_1 = \sqrt{g/l}$, in the second case: $\omega_2 = \sqrt{(g/l) + (2k/m)}$. If only the first pendulum deviates to a side, which corresponds to the initial conditions $(x_{10}, x_{20}) = (A, 0)$, then such a deviation can be represented as the sum of two normal deviations: $(A, 0) = \left(\frac{1}{2}A, \frac{1}{2}A\right) + \left(\frac{1}{2}A, -\frac{1}{2}A\right)$. This means that the motion of the first pendulum obeys the law: $x_1 = \frac{1}{2}A\cos(\omega_1 t) + \frac{1}{2}A\cos(\omega_2 t)$, and the motion of the second pendulum obeys the law: $x_2 = \frac{1}{2}A\cos(\omega_1 t) - \frac{1}{2}A\cos(\omega_2 t)$. If $k/m \ll g/l$, then the frequencies ω_1 and ω_2 are close to each other: $\Delta\omega \approx \omega_1 \dfrac{k/m}{g/l}$, and, under superposition of two oscillations with close frequencies, one observes beats (see Subsection P4.1.1): in the time $T_\mathrm{b}/2 = \pi/\Delta\omega$, the second pendulum is in full swing, and the first pendulum stops, and after the same time period, the energy is again transferred to the first pendulum, etc.

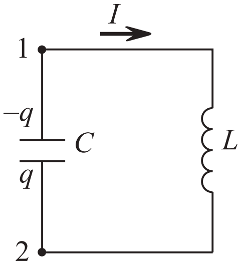

Figure P4.5. Electric oscillatory circuit.

► **Free oscillations in electric circuit.** The oscillatory circuit is a closed circuit consisting of a capacitor of capacitance C and a coil of inductance L (Fig. P4.5). The processes in an oscillatory circuit, just as in alternating current circuits, are studied in the domains of frequencies, where the *quasi-stationarity* condition is satisfied (see Subsection P3.10.1); that is, $\omega \ll c/l$, where l are typical dimensions of the system (in this approximation, in particular, one can neglect the circuit radiation). For the chosen rule of bypassing the circuit, the Ohm law for the subcircuit containing the inductance and for the capacitor charge has the form: $IR = (\varphi_1 - \varphi_2) + \mathscr{E}$, where R is the resistance of the wires and the coil. Taking the relations $I = \dot{q}$ (that holds the chosen signs), $q = (\varphi_2 - \varphi_1)/R$, and $\mathscr{E} = -L\dot{I}$ into account, we obtain $IR = -(q/C) - L\dot{I}$. This implies that

$$\ddot{q} + \frac{R}{L}\dot{q} + \frac{1}{LC}q = 0. \qquad \text{(P4.1.2.3)}$$

If the circuit resistance is negligibly small (which corresponds to $R \ll \sqrt{L/C}\,$), then the capacitor charge varies according to the harmonic law $q = q_m\cos(\omega t + \varphi_0)$ with angular frequency and period equal to

$$\omega = \frac{1}{\sqrt{LC}} \quad \text{(Thomson's formula)}, \qquad T = 2\pi\sqrt{LC}. \qquad \text{(P4.1.2.4)}$$

The current in the circuit varies according to the harmonic law with amplitude $I_m = \omega q_m$ with the phase lead by $\pi/2$.

Thomson's formula (P4.1.2.4) can be obtained by the energy method starting from the expression for the circuit energy:

$$W = \frac{LI^2}{2} + \frac{q^2}{2C},$$

taking into account that $I = \dot{q}$. The energy is transformed from electric into magnetic and conversely: at the moment of maxima capacitor charge, it is equal to $W = q_m^2/(2C)$, and when the capacitor charge is zero, it is equal to $W = LI_m^2/2$. The relations for the time-dependence of the magnetic and electric energy are the same as for the kinetic and potential energies in the case of mechanical oscillations.

P4.1.3. Damped and Forced Oscillations

► **Damped oscillations.** If the energy is lost in an oscillatory system, then the oscillation amplitude decreases with time. If the losses of energy of mechanical oscillations are determined by the force of viscous friction, which is proportional to the velocity for small velocities, then the equation of motion $m\ddot{x} = -\kappa x - b\dot{x}$ can be reduced to the linear differential equation

$$\ddot{x} + 2\beta\dot{x} + \omega_0^2 x = 0, \qquad \text{(P4.1.3.1)}$$

which is called the *equation of damped oscillations*. Here $\beta = b/(2m)$ is the *damping coefficient*, ω_0 is the angular frequency of natural oscillations without damping (as $\beta \to 0$). It is convenient to seek the solution of this equation in exponential form: $\tilde{x} = \tilde{A}\exp(-\gamma t)$. Substituting this into (P4.1.3.1), we obtain the quadratic equation for γ: $\gamma^2 - 2\beta\gamma + \omega_0^2 = 0$. If $\beta < \omega_0$, then the equation has two complex conjugate solutions: $\gamma_{1,2} = \beta \pm i\sqrt{\omega_0^2 - \beta^2}$, which result in equal answers, and hence one can take any of them. Applying the Euler formula (see Subsection P4.1.1), we obtain

$$x(t) = A_0 e^{-\beta t}\cos(\omega t + \varphi_0), \qquad \omega = \sqrt{\omega_0^2 - \beta^2}, \qquad \text{(P4.1.3.2)}$$

where the constants A_0 and φ_0 are determined by the initial conditions.

The function (P4.1.3.2) takes the zero value in equal time intervals $T = 2\pi/\omega$ (Fig. P4.6), and hence ω and T are conditionally called the frequency and period of damped oscillations. If $\beta \ll \omega_0$, then on each time interval $T \ll \tau \ll \beta^{-1}$, the oscillations can be assumed to be harmonic, and $A(t) = A_0\exp(-\beta t)$ has the meaning of the oscillation amplitude on this interval. Therefore (for any $\beta < \omega_0$), $A(t)$ is said to be time-dependent *amplitude of damped oscillations*. In time $\tau = \beta^{-1}$, the amplitude decreases by e times. The amplitude decrease per a period, equal to $A(t)/A(t+T) = \exp(\beta T)$, is called the *damping decrement*, and the

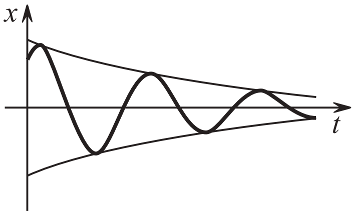

Figure P4.6. Damped oscillations.

logarithm of the decrement

$$\lambda = \ln \frac{A(t)}{A(t+T)} = \beta T \qquad \text{(P4.1.3.3)}$$

is called the *logarithmic damping decrement*. The quantity $1/\lambda$ is the number of total oscillations in which the amplitude decreases by a factor of e.

If $\beta > \omega_0$ (strong damping), then the quadratic equation for γ has two real positive roots: $\gamma_{1,2} = \beta \pm \sqrt{\beta^2 - \omega_0^2}$, and the general solution

$$x(t) = A_1 \exp(-\gamma_1 t) + A_2 \exp(-\gamma_2 t) \qquad \text{(P4.1.3.4)}$$

is of non-oscillatory (anharmonic) character (the parameters A_1 and A_2 are determined by the initial conditions).

► **Damped electric oscillations.** Comparing the equation of oscillations in an electric circuit (P4.1.2.4) with the equation of damped oscillations (P4.1.3.1), we find the expressions for the damping coefficient and the logarithmic damping decrement:

$$\beta = \frac{R}{2L}, \qquad \lambda = \beta T = \pi \frac{R}{\sqrt{L/C}}. \qquad \text{(P4.1.3.5)}$$

The condition for weak damping $\lambda \ll 1$ has the form: $R \ll \sqrt{L/C}$ (the quantity $\sqrt{L/C}$ is called the *wave resistance of the circuit*).

► **Forced mechanical oscillations.** The motion of a system under the action of an external periodic force is called the *forced oscillations*, the external force itself is called the *driving force*. From the equation of motion $m\ddot{x} = -\kappa x - b\dot{x} + F_x(t)$, we obtain the *equation of forced oscillations*:

$$\ddot{x} + 2\beta\dot{x} + \omega_0^2 x = f(t), \qquad \text{(P4.1.3.6)}$$

where the notation $f(t) = F_x(t)/m$ is used.

The general solution of such an *inhomogeneous* (with nonzero right-hand side) equation can be represented as the sum of a particular (that is, any) solution of the inhomogeneous equation and the general solution of the homogeneous equation. (The general solution must contain free parameters, which permit satisfying any initial conditions.) The homogeneous equation is the equation of damped oscillations, its general solution (formulas (P4.1.3.2) and (P4.1.3.4)) exponentially decays in time $\tau \sim 1/\beta$. The damping of natural oscillations means the termination of the regime of transient oscillations and the beginning of the regime of *steady-state* forced oscillations whose characteristics are determined by the functions $f(t)$ and the parameters β, ω_0, but are independent of the initial conditions.

We seek a particular solution of equation (P4.1.3.6) in the form of steady-state oscillations. Because any periodic force $F_x(t)$ can be expanded in the Fourier series, it is natural to study the steady-state forced oscillations under the action of a harmonic driving force $f(t) = F_x(t)/m = (F_0/m)\cos\Omega t$. We seek them in the form of harmonic oscillations of the same frequency but with a phase shift:

$$x = A\cos(\Omega t + \varphi). \qquad \text{(P4.1.3.7)}$$

Substituting (P4.1.3.7) into equation (P4.1.3.6), we obtain

$$\begin{aligned} A &= \frac{F_0}{m\sqrt{(\omega_0^2 - \Omega^2)^2 + 4\beta^2\Omega^2}}, \\ \tan\varphi &= -\frac{2\beta\Omega}{\omega_0^2 - \Omega^2}. \end{aligned} \qquad \text{(P4.1.3.8)}$$

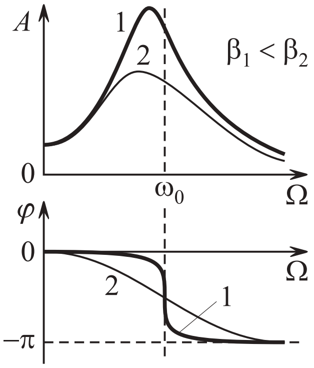

Figure P4.7. The amplitude and phase shift dependence on the frequency of the driving force.

For $\Omega = 0$, we obtain $\varphi = 0$ and $A = F_0/(m\omega_0^2) = F_0/\kappa$, which corresponds to the static displacement of the body following the slowly varying force. For $\Omega \to \infty$, we have $A \to 0$ and $\varphi \to -\pi$. The graphs of $A(\Omega)$ and $\varphi(\Omega)$ are given in Fig. P4.7.

► **Resonance.** The maximum value of the amplitude of steady-state oscillations is attained at the *resonance frequency* $\Omega_\mathrm{r} = \sqrt{\omega_0^2 - 2\beta^2} = \sqrt{\omega^2 - \beta^2}$ and is equal to $A_\mathrm{max} = A(\Omega_\mathrm{r}) = F_0/(2m\beta\omega)$, where $\omega = \sqrt{\omega_0^2 - \beta^2}$ is the angular frequency of damped oscillations. For $\beta \ll \omega_0$, the dependence $A(\Omega)$ contains a sharp and narrow maximum at the resonance frequency, which in this limit is close to the natural frequency of the system oscillations. This phenomenon is called *resonance*, and the curves of the dependence $A(\Omega)$ are the *resonance curves*. The maxima characteristics (for $\beta \ll \omega_0$) are: the ratio of A_max to the static deviation $A(0)$ is equal to $\omega/(2\beta) = \pi/\lambda$ (λ is the logarithmic damping decrement); the quantity $Q = \pi/\lambda$ is called the *quality factor* of the oscillatory system. The width of the resonance curve at the level $A_\mathrm{max}/\sqrt{2}$ is equal to the damping coefficient: $\Delta\Omega \approx \beta$.

The amplitude of steady-state oscillations of the velocity attains the maximum value $F_0/(2m\beta)$ at $\Omega = \omega_0$. At resonance, the velocity oscillations coincide in phase with the driving force oscillations.

We consider the process of establishing the oscillations in the case where the frequency driving force is equal to the resonance frequency (it is assumed that $\beta \ll \omega_0$). If, at the initial moment, the point displacement and velocity are zero, then in the limit under study the initial conditions are satisfied by the solution:

$$x \approx A_\mathrm{max} \sin\omega t - A_\mathrm{max} e^{-\beta t} \sin\omega t = A_\mathrm{max}\bigl(1 - e^{-\beta t}\bigr) \sin\omega t.$$

The obtained dependence is shown in Fig. P4.8. For $t \ll 1/\beta$, the amplitude increases proportionally to time: $A(t) \approx A_\mathrm{max}\beta t = = F_0 t/(2m\omega)$; the damping at this stage does not exhibit any influence. We note that the time of establishment of oscillations is large compared with the period: $1/\beta \gg 2\pi/\omega$. If the frequency Ω is close to ω, but differs from it, then the motion at the initial stage $t \ll 1/\beta$ is the sum of oscillations with close frequencies. If the condition $\omega \gg |\Omega - \omega| \gg 1/\beta$ is satisfied, then in the process of establishment of oscillations, profound beats can be observed (the oscillation amplitude increases almost up to $2A_\mathrm{max}$ and decreases almost to zero with period $T_\mathrm{b} = 2\pi/|\Omega - \omega|$).

Resonance under arbitrary periodic action. If the period of external action $F_x(t)$ is multiple of the period of the system natural oscillations $T = 2\pi/\omega$, then the expansion of $F_x(t)$ in the Fourier series can contain the harmonic with frequency ω. If the Q-factor of an oscillatory system is large, then harmonic oscillations of a noticeable amplitude can arise under the action of this harmonic. For example, the swings can be slightly pushed at each swing (then the first harmonic has the resonance frequency), or at the next nearest swing (then the second harmonic will work), etc.

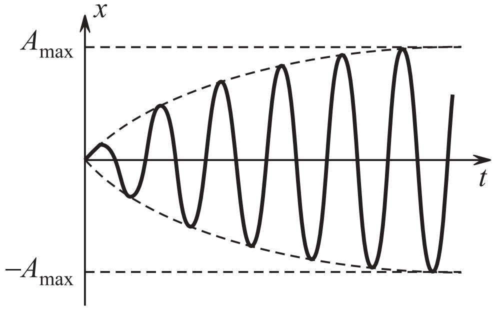

Figure P4.8. Establishment of oscillations at the resonance frequency.

► **Forced electric oscillations.** If the oscillatory circuit (see Subsection P4.2.1) contains alternating emf $\mathscr{E}(t)$, then the forced oscillations are described by the same differential equation as that for a mechanical system:

$$\ddot{q} + 2\beta\dot{q} + \omega_0^2 q = \mathscr{E}(t)/L, \tag{P4.1.3.9}$$

where q is capacitor charge, $\beta = R/(2L)$ is the damping coefficient, and $\omega_0^2 = 1/\sqrt{LC}$ is the angular frequency of the circuit natural oscillations. We consider the steady-state oscillations under the action of a harmonic force $\mathscr{E}(t) = \mathscr{E}_0 \cos\Omega t$. The charge oscillations obey the law $q(t) = q_0\cos(\Omega t + \varphi)$, where the amplitude q_0 and the phase shift φ satisfy expressions (P4.1.3.8). However, in electric circuits, it is of interest to study not the charge oscillations but the oscillations of current $I = \dot{q}$, which occur according to the law $I = I_0\cos(\Omega t - \varphi_1)$ with amplitude and phase shift equal to

$$I_0 = \mathscr{E}_0\left[R^2 + \left(\Omega L - \frac{1}{\Omega C}\right)^2\right]^{-1/2}, \qquad \tan\varphi_1 = \frac{1}{R}\left(\Omega L - \frac{1}{\Omega C}\right). \tag{P4.1.3.10}$$

The maximum of the current oscillation amplitude (resonance) is attained for $\Omega_\mathrm{r} = \omega_0 = 1/\sqrt{LC}$, and it is equal to $I_0(\Omega_\mathrm{r}) = \mathscr{E}_0/R$. At resonance, the current oscillations coincide in phase with emf oscillations.

The voltage oscillations on the resistor, capacitor, and the induction coil are described by the following formulas:

$$\begin{aligned} U_R &= IR = I_0 R\cos\bigl(\Omega t - \varphi_1\bigr),\\ U_C &= \frac{q}{C} = I_0\frac{1}{\Omega C}\cos\Bigl(\Omega t - \varphi_1 - \frac{\pi}{2}\Bigr),\\ U_L &= L\frac{dI}{dt} = I_0(\Omega L)\cos\Bigl(\Omega t - \varphi_1 + \frac{\pi}{2}\Bigr) \end{aligned}$$

(the current amplitude is the same on all the elements, because they are connected in series).

The coefficients of proportionality between the current and voltage amplitudes are called as follows: $x_C = 1/(\Omega C)$ is the *capacitive reactance* and $x_L = \Omega L$ is *inductive reactance*. The quantity $x = x_L - x_C$ is called the *reactance*, R is the *resistance* (the energy is dissipated only at this resistance), and the quantity $z = \sqrt{R^2 + x^2}$ is the *impedance* of the circuit. Formula (P4.1.3.10) can be rewritten as $I_0 = \mathscr{E}_0/z$, $\tan\varphi_1 = x/R$. All these relations become rather obvious if the vector diagrams are used (Fig. P4.9). At resonance, the reactance vanishes, $x = 0$, that is, the voltage oscillations on the capacitance and inductance compensate for each other and the circuit impedance becomes purely *resistive*, $z = R$. If the resistance of a circuit is zero, $R = 0$, the impedance is called purely *reactive*, with $z = x$.

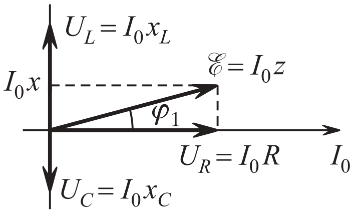

Figure P4.9. Vector diagram of currents and voltages for elements connected in series.

► **Power on a subcircuit.** The *active* or *effective value* of alternating current (voltage, emf) is the value of the constant current at which the quantity of heat released on the resistance in a period coincides with the quantity of heat released by the alternating current (that is, the mean square value over the period):

$$\int_0^T I^2 R\,dt = I_{\text{ef}}^2 RT.$$

For the sinusoidal current, $I_{\text{ef}} = I_0/\sqrt{2}$, and $U_{\text{ef}} = U_0/\sqrt{2}$. If the phase shift between the current and the voltage is φ, then the period-average power is equal to

$$P = \frac{1}{T}\int_0^T U_0 \cos(\Omega t) I_0 \cos(\Omega t - \varphi)\,dt = \frac{1}{2} U_0 I_0 \cos\varphi = I_{\text{ef}} U_{\text{ef}} \cos\varphi.$$

For purely reactive impedance, the average power is zero.

P4.2. Wave Processes

P4.2.1. Elastic and Acoustic Waves

► **Basic definitions.** If a continuum has elastic properties, then the motion of points at one place of the medium (at the *source*) results in propagation of this motion with a certain velocity in the form of an elastic wave. The medium wave motion is described by the function $\boldsymbol{\xi}(\mathbf{r}, t)$ determining the *medium particle* displacement from equilibrium $\mathbf{r}$ at time t. (The medium particle is a sufficiently small *macroscopic* element of the medium, that is, an element containing rather many atoms and molecules.) An elastic wave can propagate in three-dimensional medium, two-dimensional medium (elastic membrane), and one-dimensional medium (elastic rod, stretched rigid fiber, air column). The simplest wave mode is the *plane wave*, where the function $\boldsymbol{\xi} = \boldsymbol{\xi}(x, t)$ varies only in one direction and depends on the coordinate x. If in this case the vector $\boldsymbol{\xi}$ is perpendicular to the wave propagation direction, then the wave is said to be *transverse*, and if it is parallel, then the wave is said to be *longitudinal*.

A medium is said to be *homogeneous* if all its points are equivalent, *isotropic* if all the directions in it are equivalent, *elastic* if all forces arising in it depend only on the displacement (strain), and *linear* if the forces are proportional to the strains. In an absolutely elastic medium, the wave mechanical energy is not dissipated (is not transformed into internal energy). If the medium has only volume elasticity, then only longitudinal waves can propagate in it (liquid, gas); if it also has elasticity of form, then transverse (shear) waves are also possible. In the linear medium, the wave propagation is described by linear differential equations, and the *superposition principle* holds: if two independent sources cause two different waves $\boldsymbol{\xi}_1(\mathbf{r}, t)$ and $\boldsymbol{\xi}_2(\mathbf{r}, t)$, then the common action of the sources results in the wave $\boldsymbol{\xi}(\mathbf{r}, t) = \boldsymbol{\xi}_1(\mathbf{r}, t) + \boldsymbol{\xi}_2(\mathbf{r}, t)$. The same statement holds for a single source whose motion can be decomposed into two motions. Since any function of time can be represented as the Fourier integral in harmonic functions, it follows that the wave motion of a linear medium can be decomposed into *harmonic waves*. Through an arbitrary point of a harmonic wave, one can draw a single surface of constant phase, which is called the *wave surface*. The wave surface coinciding with the leading edge of the wave perturbation is called the *wave front*.

► **Equation of plane harmonic wave.** If the displacement in the source obeys the law $\xi(0,t)=\xi_m\cos\omega t$, then at the points with the coordinate x, the displacement occurs according to the same law, but with the delay by x/v, where v is the wave propagation velocity:

$$\xi(x,t)=\xi_m\cos\Big[\omega\Big(t-\frac{x}{v}\Big)\Big]=\xi_m\cos\Big(\frac{2\pi}{T}t-\frac{2\pi}{\lambda}x\Big)=\xi_m\cos(\omega t-kx),\qquad\text{(P4.2.1.1)}$$

where $\lambda=2\pi v/\omega=vT$ is *wavelength*, and $k=\omega/v=2\pi/\lambda$ is the *wavenumber*. The wavelength is the shortest distance between points exhibiting synchronous oscillations (the phase difference is $\Delta\varphi=2\pi$); the wavelength is the spatial period of the harmonic wave profile at any time moment. The phase difference between arbitrary points of the wave is equal to $\Delta\varphi=2\pi(x_2-x_1)/\lambda$. In equation (P4.2.1.1), it is assumed that the energy losses at the distance x are negligibly small; a small energy dissipation can be taken into account empirically introducing the factor $\exp(-\gamma x)$, where γ is *coefficient of wave damping*, in (P4.2.1.1). If we introduce the *wave vector* **k** directed perpendicularly to the wave front in the direction of wave propagation, then (P4.2.1.1) takes the form invariant under the choice of the coordinate system:

$$\xi(\mathbf{r},t)=\xi_m\cos(\omega t-\mathbf{k}\cdot\mathbf{r}),\qquad\widetilde{\xi}(\mathbf{r},t)=\widetilde{\xi}_m e^{i(\omega t-\mathbf{k}\cdot\mathbf{r})}.\qquad\text{(P4.2.1.2)}$$

The last form of the traveling wave equation is based on the Euler formula; only the real part $\operatorname{Re}\widetilde{\xi}$ has a physical meaning. If the wave velocity is independent of the frequency (there is no dispersion), then the plane wave perturbation of any form propagates without distortion.

► **Spherical and cylindrical diverging waves.** If the wave propagates from a point (spherical) or linear (cylindrical) source isotropically in all directions, then the wave surfaces have the respective shape of spheres or circular cylinders. In these cases, the equations of diverging waves without energy losses have the form:

$$\xi(r,t)=\frac{\xi_0}{r}\cos(\omega t-kr)\qquad\text{(spherical wave)},$$
$$\xi(\mathcal{R},t)=\frac{\xi_0}{\sqrt{\mathcal{R}}}\cos(\omega t-k\mathcal{R})\qquad\text{(cylindrical wave)},$$

where $r=\sqrt{x^2+y^2+z^2}$, $\mathcal{R}=\sqrt{x^2+y^2}$. The amplitude decreases because the wave surface area increases; the energy conservation law demands that the energy flux remain constant (we recall that the energy of oscillations is proportional to the squared amplitude; see also below).

► **Wave equation.** A direct substitution shows that the displacement of the harmonic wave $\xi(\mathbf{r},t)$ satisfies the equation

$$\frac{\partial^2\xi}{\partial x^2}+\frac{\partial^2\xi}{\partial y^2}+\frac{\partial^2\xi}{\partial z^2}=\frac{1}{v^2}\frac{\partial^2\xi}{\partial t^2},\quad\text{or}\quad\Delta\xi=\frac{1}{v^2}\frac{\partial^2\xi}{\partial t^2},\qquad\text{(P4.2.1.3)}$$

which is called the *wave equation*. If the harmonic wave velocity is independent of the frequency (the dependence of ω on k is linear, that is, the dispersion is absent), then any superposition of plane waves satisfies the same equation. The converse statement also holds: if the equation of motion of a particle of the medium can be reduced to (P4.2.1.3), then any wave perturbations of this medium propagate with the velocity v.

In the one-dimensional case, the general solution of equation (P4.2.1.3) has the form

$$\xi = f_1(x - vt) + f_2(x + vt), \tag{P4.2.1.4}$$

where f_1 and f_2 are arbitrary (differential) functions. The first term describes propagation of the plane signal $f_1(x)$ with velocity v without changes in the form in the direction of positive x, and the second term describes propagation of the signal $f_2(x)$ with velocity v in the direction of negative x.

Example 1. Elastic rod. The forces F arising in a thin rod of cross-sectional area S subjected to longitudinal elastic deformations obeys Hooke's law: $\sigma = E\varepsilon$, where $\sigma = F/S$ is the *stress* at a given point of the rod, ε is the strain, and E is Young's modulus. If x is the coordinate along the rod and $\xi(x,t)$ is the longitudinal displacement of the particle with coordinate x at the time t, the strain at the point x is expressed in terms of the partial derivative of the displacement as $\varepsilon = \dfrac{\xi(x+dx) - \xi(x)}{dx} \approx \dfrac{\partial \xi}{\partial x}$. The force acting on the particle of size Δx and mass $\Delta m = \rho\,\Delta x\,S$ is equal to $[\sigma(x+\Delta x) - \sigma(x)]S$. Then the equation of motion of the particle has the form

$$[\sigma(x+\Delta x) - \sigma(x)]S = \Delta m \frac{\partial^2 \xi}{\partial t^2} \quad\Longrightarrow\quad \frac{\partial^2 \xi}{\partial x^2} = \frac{\rho}{E}\frac{\partial^2 \xi}{\partial t^2}.$$

Hence, the wave propagation speed in an elastic rod is equal to $v = \sqrt{E/\rho}$. Longitudinal waves in elastic media propagate with the same speed.

Example 2. Stretched string. A transverse wave can propagate along a string whose tension is equal to T. Suppose that the string profile at a given time moment is described by the function $\xi(x,t)$ (Fig. P4.10). We obtain the equation of motion of the medium particle of dimension Δx under the assumption of low-slope wave: $\partial\xi/\partial x \ll 1$. The vertical projection of the tensile force is equal to $F_\perp(x) = T\sin\alpha \approx T(\partial\xi/\partial x)$ (α is the string inclination angle); the vertical force acting on the medium particle of dimension Δx and mass $\Delta m = \rho_{\rm lin}\Delta x\,S$ is equal to $F_\perp(x+\Delta x) - F_\perp(x)$ ($\rho_{\rm lin}$ is the linear string density). The equation of motion of the medium particle has the form

$$\frac{\partial^2 \xi}{\partial x^2} = \frac{\rho_{\rm lin}}{T}\frac{\partial^2 \xi}{\partial t^2},$$

hence the wave propagation velocity in the string is equal to $v = \sqrt{T/\rho_{\rm lin}}$.

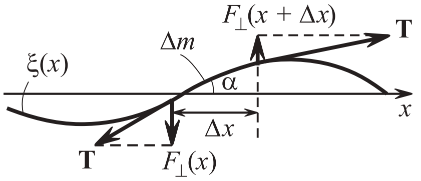

Figure P4.10. Element of a stretched string (to example 2).

Example 3. Air column in a cylinder. The volume elasticity of a gas (or any thermodynamically simple medium) is characterized by the bulk modulus of elasticity $K = -V(\partial p/\partial V) = \rho(\partial p/\partial\rho)$. The value of K depends on the condition under which bulk deformation of the gas occurs. For sound oscillations ($\nu > 16$ Hz), one can neglect the heat exchange between distinct medium particles and assume that K is the adiabatic modulus of elasticity: $K_{\rm ad} = -V\left(\partial p/\partial V\right)_{\rm ad}$. The variation in the pressure at a given point of the cylinder (for small strains) is $\Delta p(x) = -\lim_{V\to 0} K(\Delta V/V) = -\lim_{\Delta x\to 0} K[S\xi(x+\Delta x) - S\xi(x)]/(S\Delta x) = -K(\partial\xi/\partial x)$; the force acting on the air medium particle of dimension Δx and mass $\Delta m = \rho\,\Delta x\,S$ is equal to $\Delta F = [\Delta p(x) - \Delta p(x+\Delta x)]S$. The equation of motion of the medium particle has the form

$$\frac{\partial^2 \xi}{\partial x^2} = \frac{\rho}{K}\frac{\partial^2 \xi}{\partial t^2},$$

and hence the wave propagation velocity in the air cylinder is equal to $v = \sqrt{K/\rho} = \sqrt{\partial p/\partial \rho}$. (These expressions remain valid for any thermodynamically simple medium such as a real gas or a liquid.) For the sound waves in an ideal gas, we obtain: $K = \gamma p$, $v = \sqrt{\gamma p/\rho} = \sqrt{\gamma RT/\mu}$, where γ is the adiabatic exponent (see Subsection P2.2.3).

► **Volume density of energy. Energy flux density.** The densities of the kinetic and potential energies at a given point of the plane elastic longitudinal wave are equal to

$$w_{\text{k}} = \frac{\rho}{2}\left(\frac{\partial \xi}{\partial t}\right)^2, \qquad w_{\text{p}} = \frac{E}{2}\left(\frac{\partial \xi}{\partial x}\right)^2.$$

For a traveling wave of arbitrary form $\xi = f(x \pm vt)$, we have the relation $(\partial\xi/\partial t)^2 = v^2(\partial\xi/\partial x)^2$. Taking into account that $v^2 = E/\rho$ for the elastic longitudinal wave, we see that the densities of the kinetic and potential energies at each point of the traveling wave are equal to each other. This statement holds for traveling waves of any nature. In the case of a harmonic plane wave (P4.2.1.1), the wave energy per unit volume and its time average have the form:

$$w = w_{\text{k}} + w_{\text{p}} = \rho\omega^2\xi_m^2 \sin^2(\omega t - kx), \qquad \langle w\rangle = \tfrac{1}{2}\rho\omega^2\xi_m^2.$$

The energy flux density (the *Umov vector*) at a given point of the traveling wave is equal to

$$\mathbf{U} = w\mathbf{u}, \tag{P4.2.1.5}$$

where **u** is the rate of the energy transfer. In the dispersionless medium, **u** = **v**, where **v** is the wave propagation velocity contained in the wave equation (P4.2.1.4). For harmonic traveling wave (P4.2.1.1), $u = v$, where v is the phase velocity of the wave: $v = \omega/k$. The energy transferred by the traveling wave through the site $d\mathbf{s}$ per unit time (the energy flux) is equal to $d\Phi = \mathbf{U}\cdot d\mathbf{s}$. The magnitude of time-average value of the Umov vector (it is sometimes called the *wave intensity*) for a harmonic plane wave is equal to $I = |\langle\mathbf{U}\rangle| = v\langle w\rangle = \frac{1}{2}\rho v\omega^2\xi_m^2$. In the case of an arbitrary (including the standing) longitudinal elastic wave, one can use the expression for **U** in terms of the power of elastic forces (per unit area):

$$\mathbf{U} = -\sigma\frac{\partial \boldsymbol{\xi}}{\partial t},$$

where $\sigma = E\,\partial\xi/\partial x$ is the stress at a given point of the medium (see example 1). For the transverse wave in the string (example 2), the energy flux has a similar form:

$$P = -F_\perp\frac{\partial\xi}{\partial t} = -T\frac{\partial\xi}{\partial x}\frac{\partial\xi}{\partial t}.$$

► **Dispersion. Group velocity.** The dependence of the harmonic wave velocity on the frequency or the wavelength is called the *dispersion*, and the medium where this phenomenon is observed is called the *dispersion medium*. In the dispersion medium, the nonsinusoidal traveling pulse changes its shape in the process of motion, because the harmonic waves contained in its Fourier expansion move with different velocities. The energy transfer rate contained in expression (P4.2.1.5) for the Umov vector is determined in this case as the velocity of motion of the center of pulse (or as the velocity of the point at which the strain is maximum) and is called the *group velocity* of the wave packet (in contrast to the *phase velocity* of the sinusoidal wave $v = \omega/k$). A finite pulse of dimension Δx is called the *wave packet* because its expansion in the Fourier integral in harmonic waves contains a finite

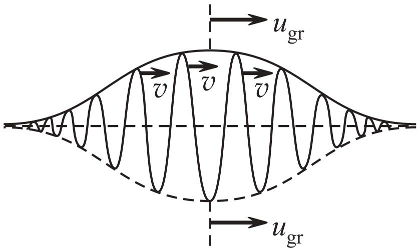

Figure P4.11. Phase and group velocities.

group of waves whose spectral width is determined by the relation: $\Delta x\,\Delta k \sim 1$. The group velocity of such a pulse is equal to

$$u_{\text{gr}} = \frac{d\omega}{dk} = v - \lambda\frac{dv}{d\lambda}, \tag{P4.2.1.6}$$

where $v = \omega/k$ is the phase velocity of the wave. The points of maxima (the "humps") inside the wave packet move with the phase velocity v, and the envelope of these maxima moves with the velocity u_{gr} (Fig. P4.11).

The notion of group velocity of a wave packet can be used only if its spectral width is small so that the dependence $\omega(k)$ can be assumed to be linear.

To illustrate this, we consider the wave that is the superposition of at most two traveling waves with close frequencies and equal amplitude:

$$\begin{aligned}\xi &= \xi_m\cos[(\omega+\Delta\omega)t-(k+\Delta k)x]+\xi_m\cos[(\omega-\Delta\omega)t-(k-\Delta k)x]\\ &= 2\xi_m\cos(\Delta\omega\,t-\Delta k\,x)\cos(\omega t-kx).\end{aligned}$$

This shows that the wave envelope has the spatial period $\Delta x = 2\pi/\Delta k$ and propagates with velocity $u = \Delta\omega/\Delta k$.

Example 4. The group velocity can be both less and greater than the phase velocity. The phase velocity of waves on the surface of a fluid for long (gravitational) waves depends on the wavelength according to the law $v = \sqrt{g\lambda/2\pi}$, and for short (capillary) waves, according to the law $v = \sqrt{2\pi\sigma/\rho\lambda}$. Substituting this in formula (P4.2.1.6), we see that the group velocity in the first case is equal to $u_{\text{gr}} = v/2$, and in the second, to $u_{\text{gr}} = 3v/2$. We also see that the group velocity can be strongly different from the phase velocity.

► **Wave interference.** Two waves are called *coherent* if, at any point of the space, they generate coherent oscillations whose phase difference does not vary in time (see Subsection P4.1.1). The sources of coherent waves are called *coherent sources*. In the case of addition of incoherent waves, the time-average energy of the resultant oscillation is equal to the sum of their average energies. In the case of addition of coherent waves and in the case of particle oscillations that occur in the same or close directions, the phenomenon of *interference* can be observed. Interference of two or more coherent waves is characterized by increased amplitudes of the resulting wave at some points of space (where wave crests meet) and decreased amplitudes at other points (where a crest of a wave meets a trough of another wave). If a point lies at the distance r_1 from one of the coherent sources and at the distance r_2 from the other, then the phase difference between the oscillations at this point is equal to

$$\Delta\varphi = (\varphi_{10}-kr_1)-(\varphi_{20}-kr_2) = 2\pi\frac{r_2-r_1}{\lambda}-(\varphi_{20}-\varphi_{10}) = 2\pi\frac{\Delta}{\lambda}-\Delta\varphi_0.$$

Here $\Delta\varphi_0$ is the phase difference between the source oscillations, $\Delta = (r_2 - r_1)$ is the *wave path difference*. The maximum conditions for the resultant oscillations is $\Delta\varphi = \pm 2\pi m$, the minimum condition is $\Delta\varphi = \pm 2\pi\left(m-\frac{1}{2}\right)$, where m is the order of the interference maximum (minimum). In the case of in-phase sources ($\Delta\varphi_0 = 0$) these conditions take the following especially simple form:

$$\begin{aligned} &\Delta = \pm m\lambda && \text{(maximum)},\\ &\Delta = \pm\bigl(m-\tfrac{1}{2}\bigr)\lambda && \text{(minimum)}. \end{aligned}$$

Example 5. We consider two linear coherent sources of cylindrical waves that are at the distance $\lambda/2$ from each other. For the points at far distances from sources, the wave propagation difference is determined only by the direction of radiation and is equal to $\Delta = \frac{1}{2}\lambda\cos\theta$ (Fig. P4.12). In the case of in-phase sources, the radiation is weakened in the direction $\theta = 0$ and reinforced in the direction $\theta = \pi/2$, and in the case of sources oscillating in opposite phase ($\Delta\varphi_0 = \pi$), the situation is opposite.

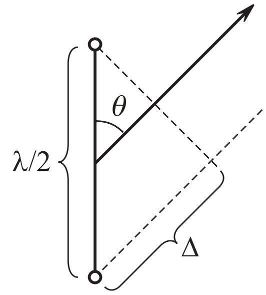

Figure P4.12. To example 5.

► **Standing waves. Natural oscillations.** An important example of interference is the *standing wave*, arising in addition of two equal plane traveling waves propagating towards each other:

$$\xi = \xi_m\cos(\omega t - kx) + \xi_m\cos(\omega t + kx) = 2\xi_m\cos kx\cos\omega t. \qquad \text{(P4.2.1.7)}$$

The oscillation amplitude $A(x) = 2\xi_m\cos kx$ of the wave points varies periodically from zero (at the wave *nodes*) to $2\xi_m$ (at the wave *antinodes*). The distance between neighboring nodes is equal to $\lambda/2$. The oscillations of points between two nodes occur in phase, but the oscillations of points on the opposite sides of the node occur in opposite phase. At the nodes, the velocity oscillation amplitude is zero, but the oscillation amplitude of the strain $\partial\xi/\partial x$ takes the maximum value. Conversely, at the antinodes, the strains are zero, but the velocity oscillations have the maximum amplitude. The time-average energy has the same value at all the points of the standing wave. The Umov vector is zero at both the nodes and antinodes and periodically changes its direction at the intermediate points.

If the end of the rod in oscillatory motion is rigidly fixed, then the displacement of the rod end points is zero; if the rod end is free, then the strain is zero. In the first case, the boundary condition has the form $\xi|_{x=0} = 0$, and in the second case, the form $\partial\xi/\partial x|_{x=0} = 0$, where the value $x = 0$ corresponds to the rod end. (The same conditions arise for the air oscillations in a cylindrical tube in the case of closed or open end of the tube. For transverse oscillations of the stretched string considered in example 2, only the first version in which the string end is fixed is possible.) If all the points of a finite rod oscillate harmonically with a single frequency, then such a motion is called a *natural* or *free oscillation* of the rod. If an infinitely long rod is mentally cut at the point where the standing wave node is located, then the boundary condition for the fixed end is satisfied; and if the cut is at the point of antinode, then the boundary condition for the free end is satisfied. Hence the free oscillations of a rod of length l in the case of two free or two fixed ends must satisfy the condition $l = \frac{1}{2}m\lambda$ or $\omega_m = \pi mv/l$ (the spectrum of natural oscillations, $m = 1, 2, \ldots$),

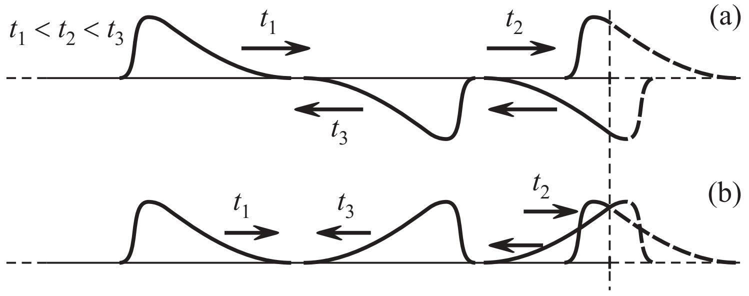

Figure P4.13. Reflection of a wave pulse from an end of a rod: (a) fixed end, (b) free end.

and in the case of one fixed end, the condition $l = \frac{1}{2}\left(m - \frac{1}{2}\right)\lambda$ or $\omega_m = \pi\left(m - \frac{1}{2}\right)v/l$. The natural oscillation with the least possible frequency is called the *fundamental oscillation*, all the other natural oscillations are *overtones* or *harmonics*.

► **Traveling wave reflection.** We consider reflection of traveling pulse from the rod end. If the rod end is fixed, then the boundary condition $\xi|_{x=0} = 0$ and the initial conditions (one incident pulse) are satisfied by the superposition of the incident pulse and the pulse of just the same form traveling towards it in which the point displacements have opposite direction (Fig. P4.13a). But if the rod end is free, then the boundary condition $\partial\xi/\partial x|_{x=0} = 0$ is satisfied by the pulse of displacements of the same sign traveling towards it (Fig. P4.13b). In the case of a harmonic traveling wave, the reflection from the free end occurs without changes in the phase, and a standing wave with antinode at the rod end is formed in this case. The reflection from the fixed end occurs with the phase shift by π, and a standing wave with node at the rod end is formed.

► **Doppler effect in acoustics.** In motion of the wave source and (or) the wave receiver with respect to the medium where the wave propagates, the registered frequency differs from the one under study (if the distance between the source and the receiver varies). We direct the axis x from the receiver to the source. If the source radiates sound with frequency ν_0 and moves along the axis x with velocity $v_x^{\rm S}$ (Fig. P4.14), then the distance between the neighboring maxima of the wave propagating along x with velocity v in the direction of the receiver is equal to $\lambda = vT_0 + v_x^{\rm S}T_0$, and its frequency is equal to v/λ:

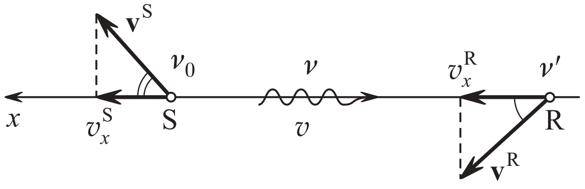

Figure P4.14. Doppler effect arises when the source (S) moves and also when the receiver (R) moves.

$$\nu = \nu_0 \frac{v}{v + v_x^{\rm S}}. \qquad \text{(P4.2.1.8)}$$

If the receiver is fixed, then precisely this frequency is registered. If the receiver moves with velocity $v_x^{\rm R}$, then the time interval between the arrival of the neighboring maxima is equal to $T' = \lambda/(v + v_x^{\rm R})$, and the frequency of the received signal is equal to $1/T'$:

$$\nu' = \nu \frac{v + v_x^{\rm R}}{v} = \nu_0 \frac{v + v_x^{\rm R}}{v + v_x^{\rm S}}. \qquad \text{(P4.2.1.9)}$$

The Doppler effect is observed if the distance between the source and the receiver varies.

P4.2.2. Electromagnetic Waves

► **Properties of electromagnetic waves.** The electromagnetic wave is the propagation of perturbations of an electromagnetic field in empty space or in a medium without sources. The existence of electromagnetic waves follows from the Maxwell theory (see Subsection P3.11.1), which states that an alternating electric field generates an alternating magnetic field and an alternating magnetic field generates an alternating electric field. In the case of a homogeneous isotropic medium, the Maxwell equation have the form

$$\begin{aligned} &1)\ \operatorname{curl}\mathbf{E} = -\frac{\partial \mathbf{B}}{\partial t}, && 2)\ \operatorname{curl}\mathbf{H} = \frac{\partial \mathbf{D}}{\partial t}, \\ &3)\ \operatorname{div}\mathbf{D} = 0, && 4)\ \operatorname{div}\mathbf{B} = 0, \end{aligned} \qquad \text{(P4.2.2.1)}$$

where $\mathbf{D} = \varepsilon\varepsilon_0\mathbf{E}$ and $\mathbf{B} = \mu\mu_0\mathbf{H}$. For the electromagnetic field depending only on the coordinate x, we obtain the equations:

$$\begin{aligned} -\mu\mu_0\frac{\partial H_z}{\partial t} &= \frac{\partial E_y}{\partial x}, & \mu\mu_0\frac{\partial H_y}{\partial t} &= \frac{\partial E_z}{\partial x}, \\ \varepsilon\varepsilon_0\frac{\partial E_y}{\partial t} &= -\frac{\partial H_z}{\partial x}, & \varepsilon\varepsilon_0\frac{\partial E_z}{\partial t} &= \frac{\partial H_y}{\partial x}. \end{aligned} \qquad \text{(P4.2.2.2)}$$

In this case, the equations for longitudinal components have the form $\partial E_x/\partial x = \partial E_x/\partial t = 0$, $\partial H_x/\partial x = \partial H_x/\partial t = 0$, that is, all longitudinal components of the field are constant quantities.

It is easy to see that the transverse components of the electromagnetic field satisfy the wave equation:

$$\Delta E_y = \varepsilon\varepsilon_0\mu\mu_0\frac{\partial^2 E_y}{\partial t^2}, \qquad \Delta H_z = \varepsilon\varepsilon_0\mu\mu_0\frac{\partial^2 H_z}{\partial t^2}$$

(the quantities E_z and H_y satisfy the same equations). It follows from these equations that the electromagnetic perturbations in a medium propagate with the velocity

$$v = \frac{1}{\sqrt{\varepsilon\varepsilon_0\mu\mu_0}} = \frac{c}{\sqrt{\varepsilon\mu}} = \frac{c}{n}, \qquad \text{(P4.2.2.3)}$$

where $c = 1/\sqrt{\varepsilon_0\mu_0} \approx 3\times 10^8\ m/c$ is the *velocity of electromagnetic waves in vacuum*, and $n = \sqrt{\varepsilon\mu}$ is the *index of refraction* of the medium.

We consider the plane electromagnetic wave of a certain frequency (the *monochromatic plane wave*) propagating along the axis x: $E_y = E_{0y}\cos(\omega t - kx)$, $E_z = E_{0z}\cos(\omega t - kx + \varphi)$. From (P4.2.2.2) we find that $H_y = -\sqrt{\varepsilon\varepsilon_0/\mu\mu_0}\,E_z$ and $H_z = \sqrt{\varepsilon\varepsilon_0/\mu\mu_0}\,E_y$. These formulas permit one to obtain the following properties of the plane traveling electromagnetic wave:

1) The electromagnetic wave is *transverse*.

2) Since $\mathbf{E}\cdot\mathbf{H} = 0$, it follows that $\mathbf{E} \perp \mathbf{H}$. The vectors ($\mathbf{E}$, $\mathbf{H}$, $\mathbf{k}$) form the right triple of vectors; that is, the direction of the vector $\mathbf{E}\times\mathbf{H}$ coincides with the direction of the wave propagation.

3) The values of the vectors $\mathbf{E}$ and $\mathbf{H}$ at each time moment are related as $\sqrt{\varepsilon\varepsilon_0}\,E = \sqrt{\mu\mu_0}\,H$ ($E = vB$).

The character of the wave polarization depends on the phase difference φ. For $\varphi = \pm m\pi$, the wave is *plane polarized*; that is, the vector $\mathbf{E}$ oscillates in one plane (this plane is called the *wave polarization plane*), and for another phase difference, the wave is *elliptically polarized*, or (for $\varphi = \pm(m + \frac{1}{2})\pi$ and for $E_{0x} = E_{0y}$), the wave is *circularly polarized* (see Subsection P4.1.1).

► **Energy of electromagnetic waves.** The volume density of the electromagnetic wave energy is calculated by the formula

$$w = \tfrac{1}{2}\varepsilon\varepsilon_0 E^2 + \tfrac{1}{2}\mu\mu_0 H^2 = \varepsilon\varepsilon_0 E^2 = \mu\mu_0 H^2 = \frac{1}{v}EH.$$

In the case of a monochromatic plane polarized wave, we have

$$w = \varepsilon\varepsilon_0 E_0^2 \cos^2(\omega t - kx), \qquad \langle w\rangle = \tfrac{1}{2}\varepsilon\varepsilon_0 E_0^2.$$

For the elliptically polarized wave:

$$w = \varepsilon\varepsilon_0\left[E_{0y}^2\cos^2(\omega t - kx) + E_{0z}^2\cos^2(\omega t - kx + \varphi)\right],$$
$$\langle w\rangle = \tfrac{1}{2}\varepsilon\varepsilon_0\left(E_{y0}^2 + E_{z0}^2\right).$$

For the wave circularly polarized ($E_{0y} = E_{0z} = E_0$, $\varphi = \frac{1}{2}\pi \pm \pi m$), the energy density does not vary in time: $w = \varepsilon\varepsilon_0 E_0^2$.

The energy flux density in an electromagnetic wave is determined by the Poynting vector (see Subsection P3.11.2):

$$\mathbf{S} = w\mathbf{v} = \mathbf{E}\times\mathbf{H},$$

which points in the direction of the wave propagation. The *intensity of an electromagnetic wave* is the magnitude of the time-average of the Poynting vector:

$$I = |\langle\mathbf{S}\rangle| = v\langle w\rangle.$$

► **Wave pressure.** According to the theory of relativity, the energy flux density of electromagnetic field in a vacuum means that there exists a momentum of the electromagnetic field. The volume density of the electromagnetic field momentum is equal (in magnitude) to w/c, the momentum flux density is equal to $\mathbf{S}/c$, and its modulus is equal to w. In the case of wave reflection or absorption, there is a variation in the wave momentum, which must manifest itself in the wave pressure on an obstacle. In the case of normal reflection of a plane wave, the pressure is equal to $p = \langle w\rangle(1+R)$, where R is the fraction of the reflected energy (the *coefficient of reflection*). Within the framework of electrodynamics, the wave pressure is explained by the action of the wave magnetic field on the current excited on reflecting surface by the wave electric field.

► **Radiation of plane current.** The simplest example of a system creating alternating fields and radiating a plane electromagnetic wave is the time-alternating plane current. We consider the current in the plane (x, z) directed along z and varying by the law $i_z = i_0\cos\omega t$ (Fig. P4.15). It follows from the second of Maxwell's equations in integral form (see Subsection P3.11.1) that the displacement current vanishes, and hence, for a narrow loop surrounding the current, we have $B_x(0,t) = \pm\frac{1}{2}\mu_0 i_0\cos\omega t$, where the minus sign corresponds to the field on the right of the plane (for small $y > 0$), and the plus sign corresponds to the field on the left of the plane. Using the relation between E and B in a plane wave, we obtain $E_z(0,t) = -A_E\cos\omega t$, where $A_E = \frac{1}{2}\mu_0 c i_0 = i_0/(2\varepsilon_0 c)$. The electric field is directed opposite to the current, its work over the current is negative; that is, the current gives energy to the wave. The field far from the plane has the form $E(y,t) = -A_E\cos(\omega t - ky)$ for $y > 0$ and $E(y,t) = -A_E\cos(\omega t + ky)$ for $y < 0$.

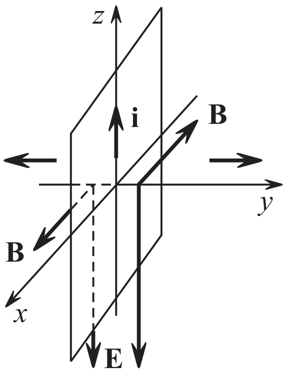

Figure P4.15. Radiation of plane current.

► **Wave radiation by moving charges.** The radiation of electromagnetic waves occurs in accelerated motion of charges. An electric dipole whose dipole moment rapidly varies in time (a *Hertz oscillator* or a *Hertz vibrator*) is a simple radiating system. Since the electromagnetic perturbations propagate with velocity c, the field of radiation at the distance r at time t is determined by the motion of charges in the dipole at time $t' = t - r/c$. The radiation field has a rather simple form only in the *wave zone*; that is, at distances that are large compared with both the dipole dimensions and $\lambda = c\tau$, where τ is the typical time of the dipole moment variation (in the case of harmonic oscillations, λ is the wavelength). The electric and magnetic fields in the wave zones are perpendicular to the radius vector $\mathbf{r}$ drawn from the dipole to the point of observation:

$$\mathbf{E} = \frac{1}{4\pi\varepsilon_0 c^2 r^3}\bigl[(\ddot{\mathbf{p}}\times\mathbf{r})\times\mathbf{r}\bigr]_{t-r/c}, \qquad \mathbf{B} = \frac{\mu_0}{4\pi c r^2}\bigl[\ddot{\mathbf{p}}\times\mathbf{r}\bigr]_{t-r/c}.$$

The mutual location of the vectors $\mathbf{E}$, $\mathbf{H}$, and $\mathbf{r}$ is shown in Fig. P4.16.

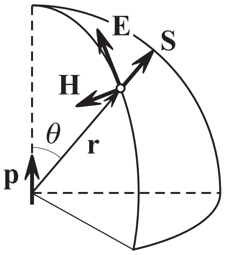

Figure P4.16. Radiation of a moving electric dipole.

The solution of the Maxwell equations in the form or retarded potentials (see Subsection P3.11.1) permits one to write the expressions for the potentials at the point $\mathbf{r}$ at time t. For example, the vector potential has the form:

$$\mathbf{A}(\mathbf{r},t) = \frac{\mu_0}{4\pi}\frac{q\mathbf{v}(t-r/c)}{r} = \frac{\mu_0}{4\pi}\frac{\dot{\mathbf{p}}(t-r/c)}{r}.$$

In calculations of $\mathbf{B} = \operatorname{curl}\mathbf{A}$, the principal role in the wave zone is played by the term arising in the argument differentiation $\dot{\mathbf{p}}$, which results in the above expression for $\mathbf{B}$. Similar but more cumbersome calculations can also be performed for the electric field.

The fields decrease with the distance according to the law $1/r$. The Poynting vector in the wave zone is directed along $\mathbf{r}$; in the direction making an angle θ with the vector $\mathbf{p}$, it is equal to

$$S = \frac{1}{4\pi\varepsilon_0}\frac{\sin^2\theta}{4\pi c^3 r^2}\bigl(\ddot{\mathbf{p}}\big|_{t-r/c}\bigr)^2.$$

The energy flux through a closed surface is precisely the power of the dipole radiation:

$$P = \int_0^\pi S(\theta) 2\pi r^2 \sin\theta \, d\theta = \frac{1}{4\pi\varepsilon_0} \frac{2\ddot{\mathbf{p}}^2}{3c^3}.$$

Assuming that only one of the dipole charges is in motion, we obtain the formula for the power of radiation of a particle in accelerated motion:

$$P = \frac{1}{4\pi\varepsilon_0} \frac{2q^2\ddot{\mathbf{r}}^2}{3c^3}, \qquad \text{(P4.2.2.4)}$$

which is proportional to its squared acceleration.

An electric dipole whose moment varies by the harmonic law, $\mathbf{p} = \mathbf{p}_0 \cos\omega t$, is a *linear harmonic oscillator*. The dependence of the radiated wave intensity on the angle θ has the form

$$I = |\langle\mathbf{S}\rangle| = \frac{1}{4\pi\varepsilon_0} \frac{p_0^2 \omega^4 \sin^2\theta}{8\pi c^3 r^2}.$$

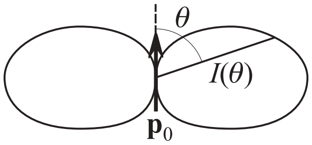

Figure P4.17. Directional pattern of a linear oscillator.

The dependence $I(\theta)$ for $r = \text{const}$ (the *directional pattern*) is shown in Fig. P4.17. The time-average power of radiation of such an oscillator

$$P = \frac{1}{4\pi\varepsilon_0} \frac{\omega^4 \mathbf{p}_0^2}{3c^3} \qquad \text{(P4.2.2.5)}$$

is proportional to the fourth power of its frequency.

Example 1. A free electron (with mass m) in the field of a plane electromagnetic wave with amplitude E_0 exhibits forced oscillations with amplitude $A = eE_0/(m\omega^2)$ (the equation of motion of the electron has the form $m\ddot{x} = -eE_0 \cos\omega t$). One can see that the radiation power of a free electron in the field of an electromagnetic wave is independent of the frequency, and the scattering cross-section (the ratio of the radiation power to the incident wave intensity) is equal to

$$\sigma = \frac{P}{I} = \frac{8}{3} \frac{(ke^2)^2}{m^2 c^4} \sim 10^{-30}\ \text{m}^2.$$

Another situation arises if, in the electromagnetic wave field, there is an atomic electron the natural frequency ω_0 of whose oscillations is large compared to the frequency of the incident (light) wave. Then the oscillation amplitude (see Subsection P4.1.3) is equal to $A = eE_0/(m\omega_0^2)$; that is, it is almost independent of ω. In this case, the radiation power and the light scattering cross-section are proportional to ω^4, which qualitatively explains the blue color of the sky (the blue color scattering is stronger).

Example 2. In a hydrogen atom, let the electron move about the nucleus in a circular orbit with a decreasing radius r and speed v. The electron energy and radiation power are

$$W = \frac{mv^2}{2} - \frac{ke^2}{r} = -\frac{ke^2}{2r}, \qquad P = \frac{2ke^2\ddot{r}}{3c^3} = \frac{2}{3} \frac{(ke^2)^3}{m^2 c^3} \frac{1}{r^4},$$

since $m\ddot{r} = mv^2/r = ke^2/r^2$. It follows from the law of conservation of energy, $P = -dW/dt$, that

$$\frac{dr}{dt} = -\frac{4}{3} \frac{(ke^2)^2}{m^2 c^3} \frac{1}{r^2}.$$

Separating the variables and integrating, we find the time in which the radius decreases from its initial value r_0 to zero (i.e., the time in which the electron falls onto the nucleus, or the *deexcitation time*):

$$t = \frac{1}{4} \frac{m^2 c^3}{(ke^2)^2} r_0^3 \sim 10^{-10}\ \text{s},$$

where $r_0 \sim 10^{-10}$ m is the atomic radius.

► **Doppler effect for electromagnetic waves in vacuum.** The main distinction from the acoustic Doppler effect (see Subsection P4.2.1) is that there is no reference system associated with the medium, where the wave propagates. Therefore, the relation between the radiation frequency ν_0 (measured in the source reference system K_S) and the registered frequency ν (measured in the receiver reference system K_R) can depend only on their relative velocity. Assume that in K_R, the source moves with velocity v directed at the angle θ made with the radius vector drawn from the receiver to the source. Repeating the argument given in Subsection P4.2.1, we obtain

$$\nu = \frac{\widetilde{\nu}_0}{1 + (v/c)\cos\theta},$$

where $\widetilde{\nu}_0$ is the source frequency measured by the clock in the system K_R. Passing to the intrinsic time ($\widetilde{T}_0 = \gamma T_0$, or $\widetilde{\nu}_0 = \nu_0/\gamma$; see Subsection P1.10.2), we obtain

$$\nu = \frac{\nu_0}{\gamma[1 + (v/c)\cos\theta]} = \frac{\nu_0\sqrt{1 - v^2/c^2}}{1 + (v/c)\cos\theta}. \qquad \text{(P4.2.2.6)}$$

One can see that, because of the time transformation, not only the longitudinal but also the transverse Doppler effect is observed (for the source motion perpendicular to the direction to the receiver).

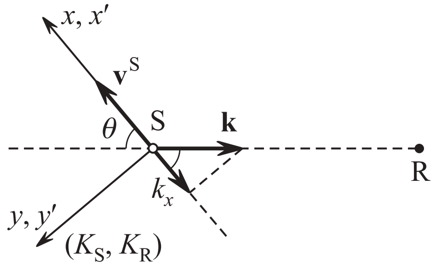

Figure P4.18. To the explanation of the Doppler effect for electromagnetic waves.

It is useful to consider the Doppler effect from a different viewpoint. Since the oscillation phase at a given point of the wave ($\omega t - \mathbf{k}\cdot\mathbf{r}$) must be invariant under the transition to another reference system, the ($\mathbf{k}, \omega/c$) is a four-vector of zero length ($k^2 - \omega^2/c^2 = 0$). If, in the frame K_R, the axis x is directed parallel to the source velocity $\mathbf{v}^\mathrm{S}$ (Fig. P4.18), then, in this reference system, we have $k_x = -k\cos\theta = -(\omega/c)\cos\theta$. Using the Lorentz transformations to pass to the frame K_S, we obtain: $\omega_0/c = \gamma[(\omega/c) - k_x(v/c)]$, or $\omega_0 = \gamma[\omega + \omega(v/c)\cos\theta]$. Expressing ω, we obtain (P4.2.2.6). This method allows us, by writing the Lorentz transformations for the wave vector $\mathbf{k}$, to obtain formulas for the light aberration phenomenon, which is important in astronomy.

► **Scale of electromagnetic waves.** Depending on the way of radiation and registration of electromagnetic waves, several ranges with conditional (overlapping) boundaries are distinguished in the scale of the frequency ν or of the wavelengths in a vacuum $\lambda = c/\nu$:

1. The radio waves ($\lambda > 0.05$ mm).
2. The optical (light) radiation (10 nm $< \lambda <$ 1 mm):
   a) the infrared (IR) radiation (770 nm $< \lambda <$ 1 mm),
   b) the visible light (380 nm $< \lambda <$ 770 nm),
   c) the ultraviolet (UV) radiation (10 nm $< \lambda <$ 380 nm).
3. The X-rays radiation (0.01 pm $< \lambda <$ 100 nm).
4. The gamma radiation (gamma rays) ($\lambda < 0.1$ nm).

Chapter P5

Optics

P5.1. Geometric Optics. Radiometry

P5.1.1. Geometric Optics

► **Fundamental laws of geometric optics.** Optics studies the electromagnetic radiation of optic (light) range (see Subsection P4.2.2) as well as phenomena arising in its propagation in space and under interaction with matter. *Geometric optics* does not consider the wave character and polarization of light radiation and deals with notions of *light rays* pointing out the direction of light propagation and narrow *light beams* formed by light rays.

The fundamental laws of geometric optics are listed below.

1. *Law of rectilinear light propagation*.

2. *Law of independence of light beams*. The energy in each beam propagates independently of other beams; illumination of the surface on which several beams are incident, is equal to the sum of illuminations created by each beam separately.

3. *Law of light reflection*. The reflected ray lies in *incidence plane*, formed by the incident ray and the normal to the surface at the point of incidence; the angle of incidence is equal to the angle of reflection. All the angles are counted from the normal.

4. *Law of light refraction*. The refracted ray lies in the plane of incidence; the ratio of the sine of the angle of incidence α_1 to the sine of angle of refraction α_2 depends on the wavelength but is independent of the angle of incidence (Snell law):

$$\frac{\sin\alpha_1}{\sin\alpha_2} = n_{21} = \frac{n_2}{n_1}. \qquad \text{(P5.1.1.1)}$$

The constant quantity n_{21} is called the *relative index of refraction* of the second medium with respect to the first one, which is equal to the ratio of (*absolute*) *indices of refraction* of each of the media (of indices of refraction of the medium with respect to a vacuum). From the viewpoint of wave optics, the absolute index of refraction shows by what factor the phase velocity of the light wave of a given frequency is less than the velocity of this wave in a vacuum:

$$v = c/n, \qquad n = \sqrt{\mu\varepsilon} \approx \sqrt{\varepsilon} \qquad \text{(P5.1.1.2)}$$

(see Subsection P4.2.2). If $n_2 < n_1$, then for $\alpha_1 > \alpha_\text{c}$, where $\sin\alpha_\text{c} = n_{21} < 1$, one observes the *total reflection of light*; that is, the refracted ray is absent. If the light ray propagates in a medium with index of refraction gradually varying along an axis (in a layered medium), then it is convenient to use formula (P5.1.1.1) in the form $n\sin\alpha = \text{const}$, where α is the angle with this axis. One can see that α varies gradually, which means that the ray is bending.

The laws of geometric optics listed above must be supplemented with the *principle of reversibility of light beams*.

► **Limits of applicability of geometric optics.** The laws of geometric optics act where the phenomena of interference, diffraction, and polarization are insignificant. This happens when the wave amplitude and its first spatial derivatives vary just slightly over the wavelength. These conditions are violated at the shadow boundary, near the geometric point of convergence of light rays (focus), where light travels past narrow diaphragms, and also light propagates through media with rapidly varying index of refraction or with strong absorption. For example, when a light beam travels past a circular diaphragm of diameter d (for holes of irregular shape, d is understood as the minimum transverse dimension), it spreads out due to diffraction at a distance $l \sim d^2/\lambda$; one can use the laws of geometric optics at small distances compared to l.

► **Huygens principle and Fermat principle.** The laws of geometric optics are closely related to the *Huygens principle* (Huygens wave construction) and the *Fermat principle*. The Huygens principle is based on abstract-wave concepts and, at each point, permits constructing an auxiliary wave surface the normal to which shows the light ray direction. To construct the wave surface at time $t+\Delta t$, one considers all the points of the wave surface at time t as sources of secondary light waves. The envelope of spherical wave surfaces of secondary waves forms a new wave surface of the principal wave.

The Fermat principle is one of the examples of variational principles that play an important role in physics. It states that the time of light propagation along the true trajectory is extremal (usually, minimum or maximum) compared with all the virtual nearby trajectories. More precisely, this time does not vary (in the first order of magnitude) for a small distortion of the trajectory.

The Huygens and Fermat principles permit obtaining the fundamental laws of geometric optics but do not permit leaving its limits.

► **Optical path length.** It is convenient to express the time of light propagation through a medium with a variable index of refraction in terms of the *optical path length* L:

$$t = \int_1^2 \frac{dl}{c/n} = \frac{L}{c}, \qquad L = \int_1^2 n\,dl. \tag{P5.1.1.3}$$

This notion is also useful in studying the interference.

► **Images in optical systems.** One of the important problems of geometric optics is the construction of *images* formed by optical systems and the study of their properties. An image is the point of intersection of ray transmitted through an optical system. Images are *real* (the rays converge after leaving the system) and *virtual* (emergent rays diverge from the virtual point of intersection of their virtual continuations). The system of reflecting and refracting spherical (and plane) surfaces perpendicular to an axis forms the image of a point source by rays incident at small angles to the axis (*paraxial approximation*). The system axis is called the *principal optic axis*. The point of convergence of rays parallel to the axis is called the *focus of the system*; the plane perpendicular to the axis and drawn through the focus is called the *focal plane*. Like the images, the foci can be real and apparent. Additionally, one introduces the notion of "apparent source" denoting the point of intersection of imaginary continuations of the converging rays incident on the system.

In what follows, we use the important property of images: the optical path lengths of all rays from the source to the image are the same; that is, the optical system does not change the path difference of rays.

The basic elements of optical systems are the simple optical systems: plane and spherical mirrors, plane and spherical refracting surfaces, and thin lenses. The image formed by each of these elements is the source for the subsequent element.

When considering a simple system, one counts all the distances from the point of intersection of this system with the principal optical axis. The distance from this point to the source is denoted by s, the distance to the image, by s', and the distance to the focus, by f (*focal distance*). To real sources, images, and foci there correspond positive values, to apparent sources, negative values.

Below are formulas relating s, s', and f for simple optical systems.

1) **Spherical mirror** of radius R:

$$\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}. \qquad \text{(P5.1.1.4)}$$

The focal distance is equal to $f = R/2$, for a concave mirror, $R > 0$, for a convex mirror, $R < 0$.

2) **Plane mirror** forms the image of a point source located behind the mirror symmetrically to the source. Formally, (P5.1.1.4) holds for it as $R \to \infty$; that is, $s' = -s$ (to a real source there corresponds a virtual image, to an apparent source, there corresponds a real image).

3) **Spherical refracting surface** of radius R with the relative index of refraction $n_{21} = n_2/n_1$:

$$\frac{1}{s}+\frac{n_{21}}{s'}=\frac{n_{21}-1}{R}.$$

For a convex surface, $R > 0$, for a concave surface, $R < 0$.

4) **Plane refracting surface** is obtained from the spherical surface in the limit as $|R| \to \infty$:

$$s' = -n_{21}s.$$

5) **Thin lens** bounded by spherical surfaces of radii R_1 and R_2. Relation (P5.1.1.4) holds, the focal distance of a thin lens is calculated by the formula:

$$\frac{1}{F}=(n_{21}-1)\left(\frac{1}{R_1}+\frac{1}{R_2}\right).$$

The radii R_1, R_2 are assumed to be positive for convex surfaces and negative for concave surfaces. The quantity $D = 1/F$ is called the *focal power*; it is measured in *dioptres* (dpt), with 1 dpt = 1/m.

The theoretical limit of the image dimensions and the resolving power of optical systems is determined by the light diffraction.

P5.1.2. Radiometry and Photometry

Radiometry studies the measurement of electromagnetic radiation at all wavelengths, including visible light. Photometry studies the measurement of light within the wavelength range visible by the human eye.

► **Characteristics of radiation in space.** The radiation power emitted by a radiation source at a given point of space in a particular direction is characterized by the *radiant intensity*, I:

$$d\Phi = I\cos\theta\, ds\, d\Omega. \qquad \text{(P5.1.2.1)}$$

The radiation power $d\Phi$ is called the *radiant flux*; it is the energy transferred per unit time through the area element ds by the light rays contained in the solid angle $d\Omega$. The angle θ is the angle between a selected direction and the normal to the area element. The product $\cos\theta\, ds$ is called the *apparent size* of the area element in the specified direction. The volume density of *radiant energy*, $u = dW/dV$, is calculated as

$$u=\frac{1}{c}\int I\, d\Omega. \qquad \text{(P5.1.2.2)}$$

In the case of isotropic radiation, $u = 4\pi I/c$. For the intensity I and the density u, one can obtain the *spectral decomposition* in frequencies or wavelengths:

$$u = \int_0^\infty u_\nu\, d\nu = \int_0^\infty u_\omega\, d\omega = \int_0^\infty u_\lambda\, d\lambda.$$

Equating the energy contained in the mutually corresponding spectral intervals, one can find the relation between distinct spectral representations. For example, by setting $u_\nu\,|d\nu| = u_\lambda\,|d\lambda|$ with $\lambda = c/\nu$ taken into account, we obtain

$$u_\nu = \left(\frac{c}{\nu^2}\right) u_\lambda.$$

Similarly, we can obtain the decomposition in two mutually perpendicular polarizations.

► **Light and energy characteristics.** The above-introduced *energy characteristics* are used to obtain an objective description of the radiation. The *photometric* or *light* characteristics take account of the sensitivity of the eye to the optical radiation. The radiant power is measured in watts and the photometric unit corresponding to it is called the *luminous flux* and is measured in *lumens* (lm). To pass to the luminous flux, it is necessary to multiply the radiant power by the *luminous efficacy* η (measured in lm/W), which is equal to $\eta_0 = 625\,\mathrm{lm/W}$ for the wavelength $\lambda_0 = 555$ nm and to $\eta_0 V_\lambda$ for other wavelengths, where V_λ is the curve of *visibility*, or *relative spectral sensitivity* of the eye ($V_\lambda = 1$ for $\lambda = 555$ nm and decreases to zero approaching the boundaries of the optical range). Recalculations from arbitrary radiant power to luminous flux can be performed by the formula $\Phi_{\mathrm{lu}} = \eta_0 \int \Phi_\lambda V_\lambda\, d\lambda$. Recalculations from other energy characteristics to luminous characteristics and conversely can be performed similarly (for example, from the radiation intensity to the light intensity).

► **Characteristics of radiation source.** The point source is characterized by the *source energy power* determined as the radiant power in a given direction per unit solid angle: $d\Phi = J\, d\Omega$. The luminous characteristic — that is, the *source luminous intensity* — is determined in terms of the luminous flow. The radiant power unit, *candela*, is one of the basic SI units (1 lm = 1 cd × 1 sr, where “cd” stands for the *candela* and “sr” stands for the *steradian*). If there is no absorption or scattering of radiation, then the radiation intensity in the same direction at the distance r from the source is equal to

$$I = \frac{J}{r^2}.$$

For area sources—that is, for radiating surfaces—the notion of *energy radiance* in a given direction B_θ is introduced (the luminous characteristic is the *brightness*). The energy power emitted by a surface element ds is equal to

$$dJ = B_\theta \cos\theta\, ds \quad \text{or} \quad d\Phi = B_\theta \cos\theta\, ds\, d\Omega, \qquad \text{(P5.1.2.3)}$$

where θ is the angle between the normal to the radiating surface and the radiation direction. The source whose B_θ is independent of the direction is called a *Lambertian source*. A Lambertian source of any shape appears uniformly bright (for example, the solar disk). The *radiant exitance* R (the luminous characteristic is the *luminous exitance*) is determined as the total radiant power in the solid angle 2π per unit area of a radiating surface:

$$R = \int B_\theta \cos\theta\, d\Omega. \qquad \text{(P5.1.2.4)}$$

For a Lambertian source, $R = \pi B$.

► **Irradiance.** The radiant energy flux per unit area of illuminated surface is called the *irradiance* and denoted E. The corresponding light quantity is called the *illuminance* and measured in *luxes* (lx), with $1\,\mathrm{lx} = 1\,\mathrm{lm}/\mathrm{m}^2$. If a point source radiation is incident at an angle θ with the normal, then

$$E = \frac{J}{r^2}\cos\theta.$$
